CURRENT NACA REPORTS

NACA TN 2323

THEORETICAL INVESTIGATION OF SUBMERGED INLETS AT LOW SPEEDS. Alvin H. Sacks and John R. Spreiter. August 1951. 48p. diagrs., photos. (NACA TN 2323)

The flow field in a submerged inlet is investigated by theoretical, wind-tunnel, and visual-flow studies. Equations are developed for the growth of the ramp-floor boundary layer for parallel, divergent, and convergent ramp walls; and a general equation is derived relating the boundary-layer pressure losses to the boundary-layer thickness. The formation of a vortex pair in the divergent-ramp inlet is discussed, and relationships are established between the vortex pressure losses and the geometry of the inlet.

NACA TN 2391

FURTHER COMPARISONS OF THEORETICAL AND EXPERIMENTAL LIFT AND PRESSURE DISTRIBUTIONS ON AIRFOILS IN CASCADE AT LOW-SUBSONIC SPEED. S. Katzoff and Margery E. Hannah. August 1951. 24p. diagrs. (NACA TN 2391)

Comparisons of theoretical and experimental lift coefficients and pressure distributions were made for five compressor-type cascades of highly cambered NACA 6-series airfoils. The experimental lift coefficients were 0.2 to 0.4 less than the theoretical for the same mean-flow direction. When the theoretical lift was made equal to the experimental lift by simply adjusting the circulation to the desired value, the Kutta condition being neglected, close agreements were obtained between the pressure distributions. The data (low-speed) were obtained by the newer technique of NACA TN 2028, and the comparisons are substantially better than those previously reported in NACA TN 1376.

NACA TN 2425

PLASTIC STRESS-STRAIN RELATIONS FOR 75S-T6 ALUMINUM ALLOY SUBJECTED TO BIAXIAL TENSILE STRESSES. Joseph Marin, B. H. Ulrich and W. P. Hughes, Pennsylvania State College. August 1951. 48p. diagrs., photos., 5 tabs. (NACA TN 2425)

Constant-stress-ratio tests, variable-stress-ratio tests, and special tests were made on a tubular 75S-T6 aluminum-alloy specimen. The stresses used were essentially biaxial and tensile stresses. The constant-stress-ratio test results gave control data and showed the influence of biaxial stresses on the yield, fracture, and ultimate strength of the material. It is possible to determine from certain variable-stress-ratio tests whether there is any significant difference between the flow and deformation type of theory. The special tests checked specific assumptions made in the theories of plastic flow.

NACA TN 2426

AN INVESTIGATION OF AIRCRAFT HEATERS. XXXIV - EXPERIMENTAL DETERMINATION OF THERMAL AND HYDRODYNAMICAL BEHAVIOR OF AIR FLOWING BETWEEN A FLAT AND A WAVE-SHAPED PLATE. L. M. K. Boelter, V. D. Sanders, G. Young, M. Morgan and E. H. Morrin, University of California. August 1951. 30p. diagrs. (NACA TN 2426)

Investigation was conducted on thermal and hydrodynamical behavior of air flowing along a passage of which one side was flat and steam-heated and the other side was wave-shaped and unheated. Turbulence produced by air flowing over wavy surfaces approximately doubles heat-transfer rate for narrow duct widths. At large duct widths, the effect is negligible. Pressure drop was greatly increased over that for a straight duct. Pressure drop was increased to at least 4 times for large duct widths and to at least 10 times for small duct widths.

NACA TN 2428

AN INVESTIGATION OF AIRCRAFT HEATERS. XXXVI - PRELIMINARY INVESTIGATION OF A COMBUSTION-TYPE AIRCRAFT HEATER. L. M. K. Boelter, W. R. Elswick, V. D. Sanders and M. W. Rubesin, University of California. August 1951. 15p. diagrs. (NACA TN 2428)

Experimental results on the thermal performance of an aircraft combustion-type heater are presented. Evaluation of the thermal effectiveness of the heater reveals that the effects of gaseous radiation and turbulence due to combustion are negligible.

NACA TN 2433

A CRITICAL REVIEW OF NOTCH SENSITIVITY IN STRESS-RUPTURE TESTS. W. F. Brown, Jr. and George Sachs. August 1951. 29p. diagrs. (NACA TN 2433)

A critical review of the English and German literature on notch rupture testing was made to establish the influence of notching on various heat-treated steels and several nonferrous alloys when subjected

to long-time loading at elevated temperatures. A correlation between rupture ductility and notch sensitivity is established for low-alloy steels. Notch rupture data are compared with data obtained at room temperature to reveal the general effects of notch geometry. Notch embrittlement observed for low-alloy steels in rupture tests is discussed with regard to a precipitation reaction and is correlated with the composition and heat treatment.

NACA TN 2434

A BIHARMONIC RELAXATION METHOD FOR CALCULATING THERMAL STRESS IN COOLED IRREGULAR CYLINDERS. Arthur G. Holms. August 1951. 49p. diagrs., 4 tabs. (NACA TN 2434)

A numerical method was developed for calculating thermal stresses in irregular cylinders cooled by one or more internal passages. The use of relaxation methods and elementary methods of finite differences was found to give approximations to the correct values when compared with previously known solutions for concentric circular cylinders possessing symmetrical and asymmetrical temperature distributions.

NACA TN 2437

SOME MEASUREMENTS OF THE EFFECT OF GASEOUS IMPERFECTIONS ON THE CRITICAL PRESSURE RATIO IN AIR AND THE SPEED OF SOUND IN NITROGEN. Coleman duP. Donaldson and Jim J. Jones. August 1951. 15p. diagrs., photos., tab. (NACA TN 2437)

Experiments were made to measure the speed of sound in nitrogen at room temperatures in the pressure range of 0 to 2000 pounds per square inch absolute and the critical pressure ratio of air expanded isentropically from stagnation conditions in the same range. The experimental results were then compared with the values obtained by using the Van der Waals equation and the Beattie-Bridgeman equation.

NACA TN 2440

WIND-TUNNEL INVESTIGATION AND ANALYSIS OF THE EFFECTS OF END PLATES ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT WING. Donald R. Riley. August 1951. 55p. diagrs., photo., 2 tabs. (NACA TN 2440)

Wind-tunnel results on end-plate effects on the aerodynamic characteristics of an unswept and untapered wing of aspect ratio 4 are presented, and experimental values of the end-plate effects on the lift-curve slope and induced drag are determined and compared with theory. Expressions are developed for the lift-drag and maximum lift-drag ratios and results compared with calculated values. A theoretical analysis is presented to indicate the effect of factors influencing the lift-drag and maximum lift-drag characteristics.

NACA TN 2441

OPTICAL METHODS INVOLVING LIGHT SCATTERING FOR MEASURING SIZE AND CONCENTRATION OF CONDENSATION PARTICLES IN SUPERCOOLED HYPERSONIC FLOW. Enoch J. Durbin. August 1951. 28p. diagrs., photos., 2 tabs. (NACA TN 2441)

Optical methods involving light scattering for measuring the size and concentration of condensation particles in supercooled hypersonic air flow are discussed. For verification of these methods, radii of ammonium-chloride particles were determined, and a comparison of these results with other measurements gave good agreement. By using these methods the size and concentration of condensation particles in supercooled hypersonic air flow were measured. A table of angular-light-intensity-distribution functions is given for use in measuring small particles having an index of refraction of 1.20, the index of refraction of oxygen and nitrogen.

NACA TN 2442

A PHOTOELASTIC INVESTIGATION OF STRESS CONCENTRATIONS DUE TO SMALL FILLETS AND GROOVES IN TENSION. M. M. Frocht, Illinois Institute of Technology. August 1951. 45p. diagrs., photos., 5 tabs. (NACA TN 2442)

Factors of stress concentration for deep, sharp, and symmetrically arranged grooves and fillets in tension members have been determined photoelastically and are given in this report. Curves are given showing the distribution of the principal stresses on the section through the grooves. Complete isopachic patterns for several basic cases of grooved bars are included.

NACA TN 2443

THE SIMILARITY LAW FOR HYPERSONIC FLOW ABOUT SLENDER THREE-DIMENSIONAL SHAPES. Frank M. Hamaker, Stanford E. Neice and A. J. Eggers, Jr. August 1951. 22p. diagrs. (NACA TN 2443)

The similarity law for steady hypersonic flow about slender three-dimensional shapes is derived in terms of customary aerodynamic parameters. The law is employed to determine simple relations for correlating the pressures, forces and moments acting on related shapes in hypersonic flows. In the special case of inclined bodies of revolution, these expressions for the forces and moments are generalized to include some significant effects of the viscous cross force.

NACA RM 51E04

INVESTIGATION OF TORSION CREEP-TO-RUPTURE PROPERTIES OF N-155 ALLOY. C. W. MacGregor and F. J. Walcott, Jr., Massachusetts Institute of Technology. August 1951. 26p. diagrs., photos., 4 tabs. (NACA RM 51E04)

An investigation of the tension creep-to-rupture properties of the alloy steel N-155 was undertaken. Rupture times in the 10-to-1000-hour range were considered and tests were made at the temperatures 1200°, 1350°, and 1500° F. The effect of stress concentration in the form of transverse circular

holes was investigated under the same conditions. Comparisons of the effects of simple combined stresses (as in torsion) were made with torsion creep-to-rupture properties.

NACA RM E51E15

COMBUSTION OF SMOKE IN DIFFUSION AND BUNSEN FLAMES. Thomas P. Clark. August 1951. 13p. diagrs., photos. (NACA RM E51E15)

Varying amounts of smoke, both in the form of concentrated filaments and dilute homogeneous mixtures with the combustible, were burned in diffusion flames of ethylene and in bunsen flames of ethylene-air mixtures. Stable flames of both types were found capable of burning large amounts of carbon smoke if the smoke was finely divided. It was found that finely divided smoke passing through the flame zone in the form of a laminar filament could be completely burned at a relative smoke-fuel carbon ratio within the filament as high as 3.5:1. Conversely, low over-all concentrations of smoke could pass through the reaction zone without burning completely, if the smoke was agglomerated into flecks of soot. The smoke was found to burn in both the inner and the outer cones of the bunsen flame.

NACA TM 1301

THE FLOW OF GASES IN NARROW CHANNELS. (Über die Strömung von Gasen in engen Kanälen). R. E. H. Rasmussen. August 1951. 46p. diagrs., photo., 2 tabs. (NACA TM 1301. Trans. from Annalen der Physik, v.29, ser.5, no.8, August 1937, p.665-697).

Measurements were made of the flow of gases through various narrow channels a few microns wide at average pressures from 0.00003 to 40 cm. Hg. The flow rate, defined as the product of pressure and volume rate of flow at unit pressure difference, first decreased linearly with decrease in mean pressure in the channel, in agreement with laminar-flow theory, reached a minimum when the mean path length was approximately equal to the channel width, and then increased to a constant value. The product of flow rate and square root of molecular number was approximately the same function of mean path length for all gases for a given channel.

NACA TM 1306

THREE PAPERS FROM CONFERENCE ON "WING AND TAIL-SURFACE OSCILLATIONS" - MARCH 6-8, 1941, MUNICH. I. REMARKS CONCERNING AERODYNAMICALLY BALANCED CONTROL SURFACES. (Bemerkung zum aerodynamisch innenausgeglichenen Ruder). H. Söhngen. II. AERODYNAMICALLY EQUIVALENT SYSTEMS FOR VARIOUS FORMS OF CONTROL SURFACES WITHIN THE SCOPE OF THE TWO-DIMENSIONAL WING THEORY. (Aerodynamische Ersatzsysteme für verschiedene Ruderformen im Rahmen der zweidimensionalen Tragflächentheorie). L. Schwarz. III. COMPARATIVE CALCULATIONS CONCERNING AERODYNAMIC BALANCE OF CONTROL SURFACES. (Vergleichsrechnungen zum aerodynamischen Ruderinnenausgleich). F. Dietze. August 1951. 47p. diagrs., tab. (NACA TM 1306. Trans. from Lilienthal Gesellschaft für Luftfahrtforschung, Berlin. Bericht 135, p.61-74).

NACA TM 1307

LATERAL CONTROL BY SPOILERS AT THE DVL. (DVL - Unterbrecherquersteuerung). M. Kramer, Th. Zobel and C. G. Esche. I. SYSTEMATIC WIND-TUNNEL TESTS CONCERNING THE PROBLEM OF LATERAL CONTROL BY SPOILERS PERMEABLE TO AIR. M. Kramer and Th. Zobel. II. CONTRIBUTION TO THE LATERAL CONTROL BY SPOILERS AT THE DVL. M. Kramer. III. FLIGHT TESTS IN THE LATERAL CONTROLS BY SPOILERS ON THE AIRPLANE MODEL FIESELER FI 156. C. G. Esche. August 1951. 82p. diagrs., photo., tab. (NACA TM 1307. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 964).

The present report describes the development of spoiler control at the DVL during the period from the end of 1936 until the beginning of 1939.

DECLASSIFIED NACA REPORTS

NACA RM E7C03

DETERMINATION OF RAM-JET COMBUSTION-CHAMBER TEMPERATURES BY MEANS OF TOTAL-PRESSURE SURVEYS. I. Irving Pinkel. March 3, 1947. 10p. diagrs., tab. (NACA RM E7C03) (Declassified from Restricted, 7/3/51)

Describes a method for determining the total temperature of the gases at the combustion-chamber outlet of a ram-jet engine from the loss in total pressure measured across the combustion chamber. Presents a working chart for determining the ratio of the total temperature of the gases at the combustion-chamber outlet to the total temperature of the gases at the combustion-chamber inlet. Values of total temperature ratio across the combustion chamber of a 20-inch ram jet were obtained at pressure altitudes from 6000 to 15,000 feet. The difference between the temperature ratio across the combustion chamber determined from the chart and that obtained from thermocouple measurement was within 6.2 percent of the thermocouple-temperature ratio and within the accuracy of thermocouple measurements.

NACA RM E7C05

INCREASE IN STABLE-AIR-FLOW OPERATING RANGE OF A MIXED-FLOW COMPRESSOR BY MEANS OF A SURGE INHIBITOR. Eugene B. Laskin and Milton G. Kofskey. April 3, 1947. 21p. diagrs., photos. (NACA RM E7C05) (Declassified from Restricted, 7/3/51)

Presents a description and design principles of a surge inhibitor for increasing the stable-air-flow operating range of a mixed-flow compressor operating at high impeller tip speeds. Test results of the compressor unit with the surge inhibitor showed a considerable gain in stable-air-flow operating range over the range of equivalent impeller tip speeds from 1255 to 1738 fps. The surge inhibitor was capable

of increasing the net stable-air-flow operating range more than 8 times its original value at an equivalent tip speed of 1550 fps. The efficiency and the pressure ratio in the normal stable-air-flow operating range were not impaired when the surge inhibitor was inoperative.

NACA RM E9E02

CRITERIONS FOR CONDENSATION-FREE FLOW IN SUPERSONIC TUNNELS. Warren C. Burgess, Jr. and Ferris L. Seashore. June 16, 1949. 41p. diagrs., photos., tab. (NACA RM E9E02) (Declassified from Confidential, 7/3/51)

The results of an investigation of water vapor condensation shocks in the air passing through supersonic tunnels are presented. Criterions for condensation free flow are established by correlating experimental observations with the Volmer theory of nuclei formation. Experimental observations were made at Mach numbers up to 2.00. The criterions are presented in a form independent of tunnel-inlet stagnation pressure and are extended theoretically to a Mach number of 4.0. Preliminary evidence of the effect of tunnel size on the criterions is presented.

NACA RM L6K22

TWO-DIMENSIONAL WIND-TUNNEL INVESTIGATION AT HIGH REYNOLDS NUMBERS OF TWO SYMMETRICAL CIRCULAR-ARC AIRFOIL SECTIONS WITH HIGH-LIFT DEVICES. William J. Underwood and Robert J. Nuber. March 12, 1947. 35p. diagrs., photos., 2 tabs. (NACA RM L6K22) (Declassified from Restricted, 7/3/51)

The investigation was made of airfoils of 6-percent and 10-percent thickness equipped with 0.20-chord plain trailing-edge flaps, 0.15-chord drooped-nose flaps, and 0.10-chord leading-edge extensible flaps. The tests were run at high Reynolds numbers and low Mach numbers ($M \leq 0.14$). Maximum section lift coefficients of 1.95 and 2.03 were obtained at a Reynolds number of 6×10^6 for the optimum combination of drooped-nose and plain flaps for the 6- and 10-percent-thick airfoils, respectively.

NACA RM L8K26

CALCULATION OF AERODYNAMIC FORCES ON A PROPELLER IN PITCH OR YAW. John L. Crigler and Jean Gilman, Jr. February 15, 1949. 32p. diagrs. (NACA RM L8K26) (Declassified from Restricted, 7/3/50)

An analysis was made to determine the applicability of existing propeller theory and the theory of oscillating airfoils to the problem of determining the magnitude of the forces on propellers in pitch or yaw. Strip calculations using compressible airfoil characteristics were first made as though steady-state conditions existed successively at several blade positions of the propeller blades during one revolution. A theory of oscillating airfoils in pulsating incompressible potential flow was then considered from which it was possible to determine factors which would modify the steady-state forces.

BRITISH REPORTS

N-9011*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) STURGEON T.T. MK.2 VR.363 (2 MERLIN 140 S/1). CLIMB AND LEVEL SPEED PERFORMANCE, FUEL CONSUMPTION AND SPECIFIC AIR RANGE (WITHOUT TARGET). May 31, 1951. 26p. diagrs., 10 tabs. (AAEE Rept. A.A.E.E./845/1, pt.9)

With take-off weight of 22,100 lb and intermediate power, the maximum rate of climb was 2,030 ft/min up to full throttle height (9,800 ft), the Service ceiling was 34,800 ft, and the time to Service ceiling was 34.5 min. With weight 21,000 lb, maximum continuous power, and at the full throttle height (23,200 ft), the cruising speed was 282 knots T.A.S. With weight 20,480 lb and at cruising speed of 130 knots I.A.S., the following values were obtained for specific air range: (1) 5,000 ft, M.S. gear - 2.50 N.M.P.G.; (2) 15,000 ft, M.S. gear - 2.78 N.M.P.G.; (3) 25,000 ft, M.S. gear - 2.60 N.M.P.G.

N-9047*

Royal Aircraft Establishment (Gt. Brit.) THE G10/240E DECADE COUNTING VALVE. G. C. Rowley. April 1951. 15p. diagrs. (RAE Tech. Note MS 6)

This note describes the gas-filled decade valve recently developed by Standard Telephones and Cables Ltd., and gives details of suitable circuits. The choice of components for stepping speeds up to 30,000 pps is discussed.

N-9051*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) FIREFLY MK.5 VT.428 (GRIFFON 74). CHECK HANDLING TRIALS WITH AIR/SEA RESCUE CONTAINERS FITTED. May 25, 1951. 3p. (AAEE Rept. A.A.E.E./780,e, pt.11)

When carrying one type "G" air/sea rescue container under each wing, the handling characteristics were indistinguishable from those when carrying other underwing stores. It is considered safe, as far as handling characteristics are concerned, to clear the carriage of these units up to a maximum I.A.S. of 300 knots (the highest tested) It is considered that the carriage of the air/sea rescue container under one wing and either a 45 or 90 gallon drop tank under the other, may be cleared without further tests.

N-9129*

Royal Aircraft Establishment (Gt. Brit.) AN INSTRUMENT FOR INVESTIGATING BOUNDARY LUBRICATING PROPERTIES. E. D. Tingle. March 1951. 21p. diagrs., photo. (RAE Tech. Note Chem. 1148)

A rapid method of comparing the boundary lubricating properties of materials and the durability of

solid-lubricant films is described. A modified Wells instrument provides a record of the friction between lubricated metal surfaces at a range of sliding speeds from 0.26 to 5.1 c/s. A standard preparation technique for comparative tests is described.

UNPUBLISHED PAPERS

N-8908*

CRITICAL REVIEW OF VARIOUS REPORTS ON THE INSTABILITY OF FLAT SANDWICH PLATES. (Literatuurstudie over sandwichconstructies IV). F. J. Plantema. 16p., 4 tabs. (Trans. from Nationaal Luchtvaartlaboratorium, Amsterdam. S.364, December 1949)

Presents a review of reports on the buckling of flat sandwich plates. Various treatments on cylinders are not included, while the bending of flat plates is noted only incidentally. Considerations about the efficiency (optimum design) are also excluded.

National Advisory Committee for Aeronautics

Research Abstracts

NO. 9 OCTOBER 15, 1951

CURRENT NACA REPORTS

NACA TN 2449

INVESTIGATION OF INFLUENCE OF CHEMICAL COMPOSITION ON FORGED MODIFIED LOW-CARBON N-155 ALLOYS IN SOLUTION-TREATED AND AGED CONDITION AS RELATED TO RUPTURE PROPERTIES AT 1200° F. E. E. Reynolds, J. W. Freeman and A. E. White, University of Michigan. September 1951. 111p. diagrs., photos., 11 tabs. (NACA TN 2449)

Use of careful control over processing conditions in this investigation has shown that it is possible to correlate stress-rupture properties of forged alloys of the low-carbon N-155 alloy type at 1200° F with systematic variations in chemical composition and that a wide range in properties can be obtained by such variations. However, no alloy was obtained which had properties which were outstanding compared with those of the standard basic analysis of low-carbon N-155 alloy.

NACA TN 2466

A GENERAL CORRELATION OF TEMPERATURE PROFILES DOWNSTREAM OF A HEATED AIR JET DIRECTED PERPENDICULARLY TO AN AIR STREAM. Edmund E. Callaghan and Robert S. Ruggeri. September 1951. 37p. diagrs. (NACA TN 2466)

An experimental investigation was conducted to determine the temperature profile downstream of a heated air jet directed perpendicularly to an air stream. The profiles were determined at several positions downstream of the jet as a function of jet density, free-stream density, jet velocity, jet temperature, free-stream velocity, and orifice flow coefficient. A method is presented which yields a good approximation of the temperature profile in terms of dimensionless parameters of the flow and geometric conditions.

NACA TN 2487

EFFECT OF GROUND INTERFERENCE ON THE AERODYNAMIC CHARACTERISTICS OF A 42° SWEPTBACK WING. G. Chester Furlong and Thomas V. Bollech. October 1951. 24p. diagrs., photos. (NACA TN 2487. Formerly RM L8F04)

The effects of ground interference on the aerodynamic characteristics of a 42° sweptback wing have been determined at distances above the ground 0.68 and 0.92 of the mean aerodynamic chord (measured from the 0.25 mean aerodynamic chord). The wing was tested without flaps and with inboard trailing-edge split and outboard leading-edge flaps deflected. The wing had an aspect ratio of 4, a taper ratio of 0.625, and NACA 64_1-112 airfoil sections perpendicular to the 0.273 chord line. The results are, in general, comparable to those reported for unswept wings. The longitudinal stability at the stall was not materially affected at the ground heights of the present tests.

NACA TN 2492

A METHOD OF SOLVING THE DIRECT AND INVERSE PROBLEM OF SUPERSONIC FLOW ALONG ARBITRARY STREAM FILAMENTS OF REVOLUTION IN TURBOMACHINES. Chung-Hua Wu and Eleanor L. Costilow. September 1951. 25p. diagrs. (NACA TN 2492)

A method is presented for the determination of the supersonic flow past arbitrary turbomachine blades along stream surfaces of revolution and for the design of these blades for a prescribed velocity or turning distribution around the blades. The shapes of the stream surfaces are arbitrary. The method takes into account the variable distance between adjacent stream surfaces.

NACA TN 2494

LIFT AND MOMENT ON OSCILLATING TRIANGULAR AND RELATED WINGS WITH SUPERSONIC EDGES. Herbert C. Nelson. September 1951. 34p. diagrs. (NACA TN 2494)

The linearized velocity potential for a thin, flat, tri-triangular or related wing with supersonic edges, undergoing harmonic torsional oscillations and vertical translations in a constant supersonic stream, is derived in terms of a frequency parameter. Closed expressions for the velocity potential, section force and moment coefficients for the triangular wing are developed to the third power of the frequency of oscillation.

NACA TN 2497

GENERALIZED CONICAL-FLOW FIELDS IN SUPERSONIC WING THEORY. Harvard Lomax and Max. A. Heaslet. September 1951. 45p. diagrs. (NACA TN 2497)

Linearized, compressible-flow analysis is applied to the study of quasi-conical supersonic wing theory. Single-integral equations are derived which relate either the loading to the shape of a lifting surface or the thickness of a symmetrical wing to the pressure distribution for triangular wings with subsonic lead-

ing edges. The forms of these equations and their inversions are simplified through the introduction of the finite part and the generalized principal part of an integral. Applications of the theory, in the lifting case, include previously known results. In the nonlifting case, it is shown that for a specified pressure distribution the theory does not always predict a unique thickness distribution. This is demonstrated for a triangular plan form having a constant pressure gradient in the stream direction.

NACA TN 2498

FLIGHT INVESTIGATION OF THE EFFECT OF ATMOSPHERIC TURBULENCE ON THE CLIMB PERFORMANCE OF AN AIRPLANE. Harry Press and Herbert C. McClanahan, Jr. October 1951. 30p. diagrs., 5 tabs. (NACA TN 2498)

The results of an investigation consisting of a series of one-engine climb tests with a twin-engine transport airplane indicate that light turbulence of the type generally present in clear air over flat terrain has no significant effect on the average rate of climb for a series of runs. Turbulence does, however, increase the variation in the rate of climb from run to run. The standard deviation of the rate of climb attributable to turbulence decreases rapidly when the climb duration is increased from 1 to 5 minutes.

NACA TN 2500

A COMPARISON OF THE TURBULENT BOUNDARY-LAYER GROWTH ON AN UNSWEPT AND A SWEPT WING. John M. Altman and Nora-Lee F. Hayter. September 1951. 30p. diagrs., photos. (NACA TN 2500)

Turbulent boundary-layer measurements are presented for a 45° swept and a two-dimensional unswept wing. A comparison is made of the displacement thickness, the momentum thickness, and the shape parameters for the two wings based on the component of velocity normal to the leading edge. The tests were conducted at a Reynolds number of about 4 million based on the component of velocity normal to the leading edge.

NACA TN 2501

EXPRESSIONS FOR MEASURING THE ACCURACY OF APPROXIMATE SOLUTIONS TO COMPRESSIBLE FLOW THROUGH CASCADES OF BLADES WITH EXAMPLES OF USE. John T. Sinnette, Jr., George R. Costello and Robert L. Cummings. October 1951. 33p. diagrs. (NACA TN 2501)

Four necessary conditions for steady irrotational compressible flow through a straight cascade of blades are derived from the irrotationality condition and the conservation of mass and momentum, and these conditions are used to obtain expressions for measuring the accuracy of approximate compressible flow solutions. Application to typical compressor cascades indicated that an approximation based on linear relation between pressure and specific volume is considerably more accurate than the incompressible approximation or the Prandtl-Glauert approximation.

NACA TN 2502

EXAMPLES OF THREE REPRESENTATIVE TYPES OF AIRFOIL-SECTION STALL AT LOW SPEED. George B. McCullough and Donald E. Gault. September 1951. 52p. diagrs., photo., 6 tabs. (NACA TN 2502)

A summary of airfoil-section stalling characteristics, based on experimental investigations of five airfoil sections, is presented. Section stalling characteristics of three types are considered and are designated: trailing-edge stall, leading-edge stall, and thin-airfoil stall. The corresponding boundary-layer flows are discussed, and illustrative examples of the force, moment, pressure-distribution, and boundary-layer characteristics of each type are furnished.

NACA RM A51G09

SCHLIEREN INVESTIGATION OF THE WING SHOCK-WAVE BOUNDARY-LAYER INTERACTION IN FLIGHT. George E. Cooper and Richard S. Bray. September 1951. 26p. diagrs., photos. (NACA RM A51G09)

Schlieren photographs obtained in flight of the shock-wave interaction with a thick turbulent boundary layer on a wing are presented together with measured boundary-layer characteristics. Good correlation with theoretical and wind-tunnel investigations of boundary-layer shock-wave interaction was obtained, particularly with respect to the lower Mach number for the establishment of a forked or bifurcated type of shock wave.

NACA RM E51G20

PRELIMINARY RESULTS OF A DETERMINATION OF TEMPERATURES OF FLAMES BY MEANS OF K-BAND MICROWAVE ATTENUATION. Leonard Rudlin. September 1951. 20p. diagrs. (NACA RM E51G20)

The temperature effects on the attenuation of K-band microwaves, at a frequency of 26,500±30 megacycles per second, through natural-gas and propane flames containing added alkali halide salts, were investigated over a temperature range from 1900° to 2500° K. The preliminary data of this investigation indicated that the attenuation varies appreciably with the sodium-line-reversal temperatures of the flames and is independent of the particular hydrocarbon fuels that were used for temperature sources and of the particular halide components of the compounds used, in the concentrations employed to produce easily measurable attenuation. A reproducibility of ±25° K was obtainable.

NACA RM E51G24

RESOLUTION OF ANNEALING EXPERIMENTS FOR THE STUDY OF NONEQUILIBRIUM STATES. Philip Schwed. September 1951. 15p. diagrs. (NACA RM E51G24)

The two techniques for conducting annealing experiments for the purpose of determining the distribution of atoms of a solid among nonequilibrium states are

considered. Related definitions for resolving power for annealing with steadily rising temperature and for annealing at a series of fixed temperatures are given. The necessary separation of activation energies for the resolution of two different nonequilibrium states is found to be greater in the case of a steadily rising temperature, but of the order of 10 percent of the activation energy for both techniques. The resolving power in the case of a steadily rising temperature is independent of the rate of temperature rise.

NACA TM 1277

PRESENT STATE OF DEVELOPMENT IN NON-STEADY MOTION OF A LIFTING SURFACE. (Lo stato attuale delle ricerche sul moto instazionario di una superficie portante). P. Cicala. October 1951. 96p. diagrs., 3 tabs. (NACA TM 1277. Trans. from Aerotecnica, v.21, no.9-10, Sept.-Oct.1941, p.557-591, 670-685, 759-773).

A summary is given of the principal results on air forces for a wing undergoing unsteady motion in an incompressible fluid and of methods followed by various investigators, as of 1941. Part I contains results for a wing of infinite aspect ratio; part II deals with procedures for wings of finite aspect ratio; part III contains results for force components in the direction of motion (propulsion or drag); part IV considers the results of some experimental investigations. Each part contains an evaluation of existing publications.

NACA TM 1314

ON THE TURBULENT FRICTION LAYER FOR RISING PRESSURE. (Zur turbulenten reibungsschicht bei druckanstieg). K. Wieghardt and W. Tillmann. October 1951. 46p. diagrs. (NACA TM 1314. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. UM 6617, November 20, 1944).

Among the information presented are included displacement, momentum, and kinetic energy thicknesses, shearing stress distributions across the boundary layer, and surface friction coefficients. The Gruschwitz method and its modifications are examined and tested. An energy theorem for the turbulent boundary layer is introduced and discussed but does not lead to a method for the prediction of the behavior of the turbulent boundary layer because relations for the shearing stress and the surface friction are lacking.

NACA TM 1315

DISPLACEMENT EFFECT OF THE LAMINAR BOUNDARY LAYER AND THE PRESSURE DRAG. (Verdrängungswirkung der laminaren Grenzschichten und Druckwiderstand). H. Görtler. October 1951. 43p. diagrs., 3 tabs. (NACA TM 1315. Trans. from Ingenieur-Archiv, v.14, 1944, p.286-305).

The displacement effect of the boundary layer on the outer frictionless flow is discussed for both steady and unsteady flows. The analysis is restricted to cases in which the potential flow pressure distribution remains valid for the boundary-layer calculation. Formulas are given for the dependence of the pressure drag, friction drag, and total drag of circular cylinders on the time from the start of motion for cases in which the velocity varies as a power of the time. Formulas for the location and for the time for the appearance of the separation point are given for two dimensional bodies of arbitrary shape.

A SIMPLE TEST GEAR FOR MEASUREMENT OF EXTINCTION VOLTAGE OF COLD CATHODE DIODES UNDER DYNAMIC CONDITIONS. N. E. G. Hill. May 1951. 8p. diagrs., 3 tabs. (RAE Tech. Note EL.21)

Describes a test gear developed to enable extinction voltage data to be collected on cold cathode diodes under operating conditions. The test gear is a simple variant of the striking voltage test gear which has been described in an earlier report. It enables the striking and extinction voltages of a diode to be measured simultaneously to the nearest 1 volt.

PHOTOGRAPHIC LENS TESTING. R. W. Fish. March 1951. 31p. diagrs., photos. (RAE Tech. Note Ph.443)

The methods used at present by the Royal Aircraft Establishment for the testing of lenses designed for air photography are given in detail. The apparatus and standard conditions for the measurement of the lens resolving power are described, and the treatment and accuracy of the experimental data discussed. Extension of the resolving power measurements to the focusing of cameras and the estimation of cine-camera performance are briefly described.

THE EVALUATION OF PERSPEX JOINTING TECHNIQUES. January 1951. 43p. diagrs., photos., 40 tabs. (MOS S & TM 5/51; Fairey Aviation Co., Ltd., Hayes)

Describes a program of work carried out to afford a comparison of joint strengths in Perspex when the jointing is effected by an acrylic dough and a solvent cement. It was also desired to obtain the relevant design data. Results are given for tension, bend and shear strengths at ambient temperatures, +70°C, and -70°C, for both plasticized and unplasticized Perspex. It has been shown that joints made with an acrylic dough afford higher ultimate strengths than those made with a solvent cement. It is also apparent that various imperfections in the joint produce considerable reduction in joint strength.

THE BURNING OF SINGLE DROPS OF FUEL. PART II. EXPERIMENTAL RESULTS. G. A. E. Godsave. April 1951. 19p. photos., diagrs., 3 tabs. (NGTE R.87)

This is Part II in the series of reports describing investigations of the mechanism of the combustion of the individual drops in a liquid fuel spray. This report gives results of experimental measurements of the burning rates of single drops of various fuels suspended in still air on a fine silica filament. Over the range of drop diameter investigation (2,000-1,000μ), the burning drops decreased in size at a mass rate proportional to the first power of their diameters. The burning rate at any diameter, and hence the total drop life, may be characterized by a constant λ called the evaporation constant. Using the experimental technique described in this report, it was possible to determine the values of the evaporation constant λ for a series of pure hydrocarbons and commercial fuels.

ON THE ERRORS INVOLVED IN MEASURING SUPERSONIC MACH NUMBERS. W. T. Lord and D. Beastall. April 1951. 43p. diagrs., tab. (RAE Aero 2100)

This note presents a method of finding the errors to be expected in deriving the Mach number at a point in a supersonic flow from the formulas which depend on the pitot, static, and stagnation pressures at that point, when the errors involved in the pressure readings can be estimated. It thus suggests the best formula to use in any given case. The method is illustrated by a series of figures covering values of Mach number from 1 to 4, when no pressure has an error more than four times greater than that of any other. Other cases may be computed as required.

CORROSION OF SURFACE TREATED ALUMINUM ALLOYS. Fred M. Reinhart. 1951. 9p. diagrs., 2 tabs. (National Bureau of Standards. Rept. 1004)

Panels of aluminum alloy 24S-T3, surface-treated by the Alrok 14 and Bonderite 170 processes, were exposed in a salt fog cabinet, tidewater and marine atmosphere, both unpainted and painted, to evaluate their protective merits in these environments. The unpainted Alrok 14 surface-treated material was more resistant to corrosive attack in the tidewater and marine atmosphere than was the Bonderite 170 treated material. The Alrok 14 treated material was susceptible to the pitting type of corrosive attack only while the Bonderite 170 treated material was susceptible to intergranular attack. Both surface treatments were good bases for paint coatings in both environments for 24 months.

NACA TN 2467

THE AERODYNAMIC BEHAVIOR OF A HARMONICALLY OSCILLATING FINITE SWEPTBACK WING IN SUPERSONIC FLOW. Chieh-Chien Chang, Johns Hopkins University. October 1951. 76p. diagrs. (NACA TN 2467)

By an extension of Evvard's "diaphragm" concept outside the wing tip, two approximate methods are presented for calculating the aerodynamic behavior of harmonically oscillating, sweptback finite wings with both supersonic leading and trailing edges - one expressing the integration in terms of Fresnal integrals and the second one similar to the first except that a series expansion of the source-strength function is used. If the wing frequency parameter is small both methods give accurate results in the engineering sense without requiring undue computing skill. A number of graphs are presented to show pressure distribution of the wings at different Mach numbers, sweepback angles, and frequency parameters. Comparisons of pressure coefficients calculated from present methods and exact two dimensional solutions based on linearized theory are made.

NACA TN 2468

INVESTIGATION AT LOW SPEED OF 45° AND 60° SWEPTBACK, TAPERED, LOW-DRAG WINGS EQUIPPED WITH VARIOUS TYPES OF FULL-SPAN, TRAILING-EDGE FLAPS. John J. Harper, Georgia Institute of Technology. October 1951. 53p. diagrs., photos., 3 tabs. (NACA TN 2468)

An investigation was made to determine the low-speed aerodynamic characteristics of two sweptback, low-drag, tapered wings equipped with full-span split and slotted flaps and three special types of trailing-edge flaps. Sweep angles of 45° and 60° measured at the quarter chord were used. The results showed no appreciable gain in maximum lift coefficients for either the split flap or the special flaps on the 60° model but these same flaps did produce an increment in lift on the 45° model. The slotted flap produced the largest increase in lift on both models. The effect of the flaps on drag and pitching moment is the same as that indicated by other test data available. The slotted flap caused the largest increase in pitching moment for a given deflection angle. All flap configurations increased the stability of both wings.

NACA TN 2469

RUPTURE PROPERTIES OF LOW-CARBON N-155 TYPE ALLOYS MADE WITH A COLUMBIUM-TANTALUM FERRO-ALLOY. J. W. Freeman, E. E. Reynolds and A. E. White, University of Michigan. October 1951. 11p. diagrs., 2 tabs. (NACA TN 2469)

An experimental columbium-tantalum ferro-alloy was substituted for ferro-columbium in making laboratory heats of low-carbon N-155 alloy and an N-155 type alloy (20Cr-20Ni-20Co+2Cb). This substitution had no significant effect upon stress-rupture and creep properties of either alloy at 1200° and 1500° F. The results indicate the probable practicality of using high-tantalum ferro-columbium for making columbium-bearing heat-resistant alloys. In addition to using columbium not otherwise available, an actual reduction of the amount of columbium used is indicated.

NACA TN 2472

FUNDAMENTAL EFFECTS OF COLD-WORKING ON CREEP PROPERTIES OF LOW-CARBON N-155 ALLOY. D. N. Frey, J. W. Freeman and A. E. White, University of Michigan. October 1951. 45p. diagrs., photos. (NACA TN 2472)

Effects of cold-working under various conditions on the creep resistance at 1200° F and on the internal structure of low-carbon N-155 were determined in part by microscopic examination and X-ray diffraction. Effects of annealing at various times and temperatures on creep resistance and internal structure of the cold-worked samples were also partially evaluated. Cold-working was found to improve the creep resistance of this alloy by the introduction of residual elastic stresses into the lattice. These stresses acted to prevent the movement of the fundamental creep flow units.

NACA TN 2474

EMPIRICAL RELATION BETWEEN INDUCED VELOCITY, THRUST, AND RATE OF DESCENT OF A HELICOPTER ROTOR AS DETERMINED BY WIND-TUNNEL TESTS ON FOUR MODEL ROTORS. Walter Castles, Jr. and Robin B. Gray, Georgia Institute of Technology. October 1951. 72p. diagrs., photos., 8 tabs. (NACA TN 2474)

The empirical relation between the induced velocity, thrust, and rate of vertical descent of a helicopter rotor was calculated from wind-tunnel force tests of four model rotors by the application of blade element theory to the measured values of the thrust, torque, blade angle, and equivalent free-stream rate of descent. The tests covered the useful range of the ratio of thrust coefficient to effective solidity and the range of vertical descent from hovering to descent velocities slightly greater than those for autorotation. Possible sources of discrepancy between

previous flight and wind-tunnel test data are discussed and the principal effects of blade taper and twist on the vertical-descent characteristics are evaluated.

NACA TN 2475

SOME FEATURES OF ARTIFICALLY THICKENED FULLY DEVELOPED TURBULENT BOUNDARY LAYERS WITH ZERO PRESSURE GRADIENT. P. S. Klebanoff and Z. W. Diehl, National Bureau of Standards. October 1951. 55p. diagrs., photos. (NACA TN 2475)

Results are presented of tests to determine the feasibility of artifically thickening a turbulent boundary layer on a flat plate. It is shown that it is possible to do substantial thickening and obtain a fully developed turbulent boundary layer which is free from any distortions introduced by the thickening process. Measurements of mean velocity, spectrum of u-fluctuation, and intensity of u-fluctuation are presented. Some features of the fully developed turbulent boundary layer with zero pressure gradient are discussed. The mean flow in the boundary layer is compared with the logarithmic laws of mean-velocity distribution derived for pipes and channels, and the existing theories dealing with the shape of the spectrum in isotropic turbulence are applied to the spectrum measured in the outer portion of the boundary layer.

NACA TN 2496

FLIGHT INVESTIGATION OF A MECHANICAL FEEL DEVICE IN AN IRREVERSIBLE ELEVATOR CONTROL SYSTEM OF A LARGE AIRPLANE. B. Porter Brown, Robert G. Chilton and James B. Whitten. October 1951. 47p. diagrs., photos. (NACA TN 2496)

Data are presented showing the flight characteristics of a large airplane having a control-surface booster and mechanical feel device in the elevator-control system. The tests were made with various force gradients provided by the adjustable feel device. The booster was set to operate at a very high boost ratio throughout the tests so that the measured or apparent stick-free stability would be influenced only slightly by the aerodynamic hinge moments. The results show the effect of the feel device on the handling qualities of the test airplane and also the design features which should be incorporated in such feel devices.

NACA TN 2499

LAMINAR FRICTION AND HEAT TRANSFER AT MACH NUMBERS FROM 1 TO 10. E. B. Klunker and F. Edward McLean. October 1951. 22p. diagrs. (NACA TN 2499)

Velocity and temperature profiles and laminar boundary-layer characteristics have been computed for Mach numbers from 1 to 10, utilizing experimental values of the heat capacity, viscosity, and conductivity. The analysis shows that an effective temperature, which is a function of the surface temperature and stream conditions, arises naturally and is the proper reference temperature to be used in heat-transfer calculations. The effective temperature and the recovery temperature become identical for the condition of zero heat transfer.

NACA TN 2506

AN ANALYTIC DETERMINATION OF THE FLOW BEHIND A SYMMETRICAL CURVED SHOCK IN A UNIFORM STREAM. C. C. Lin and S. F. Shen, Massachusetts Institute of Technology. October 1951. 45p. diagrs. (NACA TN 2506)

A power-series-expansion method is used to determine the flow pattern behind a detached curved shock in a uniform stream. The limitations of the method are discussed and earlier applications are extended to include more terms and to give improved accuracy. The analysis is carried out in a manner applicable to both the two-dimensional and the axially symmetrical cases. The particular example with free-stream Mach number 1.7 is computed in the axially symmetrical case by using a fourth-degree polynomial to represent the flow and comparison is made with experimental results.

NACA TN 2509

A SELF-SYNCHRONIZING STROBOSCOPIC SCHLIEREN SYSTEM FOR THE STUDY OF UNSTEADY AIR FLOWS. Leslie F. Lawrence, Stanley F. Schmidt and Floyd W. Looschen. October 1951. 30p. diagrs., photos., tab. (NACA TN 2509)

A description and several examples of an application of a self-synchronized stroboscopic schlieren system are presented. The instrument provides for visual examination of unsteady flow phenomena occuring about aerodynamic bodies in wind tunnels. The frequency limitations of the instrument were arbitrarily selected for a particular test and may be varied by modifying electronic circuits of the system. Complete circuit diagrams are presented.

NACA TN 2510

EXPERIMENTAL VALUES OF THE SURFACE TENSION OF SUPERCOOLED WATER. Paul T. Hacker. October 1951. 20p. diagrs., photos., tab. (NACA TN 2510)

The surface tension of water has been determined experimentally for the temperature range, 0° to -22.2° C. The weak inflection point in the surface-tension - temperature relation, as indicated by the International Critical Table values for temperatures down to -8° C, was substantiated by the measurements in the temperature range, 0° to -22.2° C. The surface tension increases at approximately a linear rate from a value of 76.96 ± 0.06 dynes per centimeter at -8° C to 79.67 ± 0.06 dynes per centimeter at -22.2° C.

NACA TN 2511

CALCULATION OF HIGHER APPROXIMATIONS FOR TWO-DIMENSIONAL COMPRESSIBLE FLOW

BY A SIMPLIFIED ITERATION PROCESS. W. H. Braun and M. M. Klein. October 1951. 54p. diagrs., 10 tabs. (NACA TN 2511)

The iteration equations for a simplified solution of the nonlinear compressible-flow equation are developed and applied to two profiles, the ellipse and the Kaplan section. Limitations imposed on the solutions by simplifications in the differential equation and the boundary conditions are discussed. The velocities near the midchord, the critical and potential limit free-stream Mach numbers, and the extent of isentropic supersonic regions are calculated to four approximations for the Kaplan section and to six approximations for the ellipse. The development of the iteration equations and the presentation of the results are made in conformity with the Kármán transonic similarity law and comparisons are made with other solutions.

NACA TN 2513

EFFECTS OF SOME SOLUTION TREATMENTS FOLLOWED BY AN AGING TREATMENT ON THE LIFE OF SMALL CAST GAS-TURBINE BLADES OF A COBALT-CHROMIUM-BASE ALLOY. II - EFFECT OF SELECTED COMBINATIONS OF SOAKING TIME, TEMPERATURE, AND COOLING RATE. C. A. Hoffman and C. F. Robards. October 1951. 19p. diagrs., photos., 4 tabs. (NACA TN 2513)

An investigation was conducted to determine the effects of a number of solution and aging treatments on the life of small cast gas-turbine blades of Haynes Stellite alloy 21 (a cobalt-chromium-base alloy). Solution Treating at 2250° F followed by slow furnace cooling and subsequent aging was found to improve the mean life and the initial failure time of the blades. This improvement was confirmed by statistical analysis. Metallographic examination revealed the presence of a lamellar structure in the improved blades. Other treatments investigated did not improve blade life. The blades were operated at 1500° F and 20,000 pounds per square inch at the blade mid-span. Samples of 20 and 22 blades were used.

NACA TN 2517

AN INVESTIGATION OF AIRCRAFT HEATERS. XXXVII - EXPERIMENTAL DETERMINATION OF THERMAL AND HYDRODYNAMICAL BEHAVIOR OF AIR FLOWING ALONG A FLAT PLATE CONTAINING TURBULENCE PROMOTERS. L. M. K. Boelter, G. Young, M. L. Greenfield, V. D. Sanders and M. Morgan, University of California. October 1951. 26p. diagrs. (NACA TN 2517)

This report contains heat-transfer and pressure-drop data for air flowing over a heated flat plate containing strips of metal placed normal to the direction of air flow. The heat-transfer rates and static pressure drops are increased for this system over that for a flat plate alone because of the eddies, turbulence, and fin effect caused by the interrupters.

NACA TN 2520

EFFECTS OF PRESSURE-RAKE DESIGN PARAMETERS ON STATIC-PRESSURE MEASUREMENT FOR RAKES USED IN SUBSONIC FREE JETS. Lloyd N. Krause. October 1951. 20p. diagrs. (NACA TN 2520)

A subsonic-free-jet investigation was conducted to determine the effect of pressure-rake design parameters on static-pressure measurement. The design parameters investigated include: the location of the static orifices in relation to the tube nose and supporting strut; the proximity effects of adjacent tubes near the static orifices; and the effect of ratio of support diameter to jet diameter. The investigation covered a Mach number range of 0.3 to 0.95. Information and recommendations are provided for the design of pressure rakes to be used in subsonic free jets.

NACA TN 2521

LAMINAR BOUNDARY LAYER ON A CIRCULAR CONE IN SUPERSONIC FLOW AT A SMALL ANGLE OF ATTACK. Franklin K. Moore. October 1951. 44p. diagrs., tab. (NACA TN 2521)

The laminar boundary layer on a circular cone at angle of attack to a supersonic stream is discussed. A perturbation analysis was made to show the influence of a small angle of attack on such boundary-layer quantities as skin friction, boundary-layer thickness, viscous lift, drag, and pitching moment.

NACA RM E51H09

FLAME VELOCITIES OVER A WIDE COMPOSITION RANGE FOR PENTANE-AIR, ETHYLENE-AIR, AND PROPYNE-AIR FLAMES. Dorothy M. Simon and Edgar L. Wong. October 1951. 40p. diagrs., photos., 4 tabs. (NACA RM E51H09)

Fundamental flame velocities are reported for pentane air, ethylene-air, and propyne-air mixtures for the concentration range 60 to 130 percent of stoichiometric. A form of the Tanford and Pease equation, which includes a small constant velocity term independent of diffusion, will predict the observed changes in flame velocity.

NACA TM 1322

THEORY OF THIN-WALLED RODS. (O Teorii Tonkostennykh Sterzhnei). A. L. Goldenveizer. October 1951. 53p. (NACA TM 1322. Trans. from Prikladnaya Matematika i Mekhanika, v.13, Nov.-Dec.1949, p. 561-596).

Starting with the Love equations for bending of extensible shells, "principal stress states" are sought for a thin-walled rod of arbitrary but open cross section. Principal stress states exclude those local states arising from end conditions which damp out with distance from the ends. It is found that for rods of intermediate length, long enough to avoid local bending at a support, and short enough that elementary torsion and bending are not the most significant

stress states, four principal states exist. Three of these states are associated with the planar distribution of axial stress and are equivalent to the engineering theory of extension and bending of solid sections. The fourth state resembles that which has been called in the literature "bending stress due to torsional", except that cross sections are permitted to bend and the shear along the center line of the cross section is permitted to differ from zero.

Royal Aircraft Establishment (Gt. Brit.)
A UNIFIED THEORY OF SUPERSONIC WING FLOW, EMPLOYING CONICAL FIELDS. H. Multhropp. April 1951. 178p. diagrs. (RAE Aero 2415)

This paper attempts to unify the supersonic wing flow theory by employing conical fields with a single transformation. The theory is applied first to the case of wings wholly inside the Mach cone and then to problems of wings which are partly outside the Mach cone. Enough partial solutions are worked out to enable the full solution to be built up for a flat plate of any practicable plan form at incidence and sideslip. The problem of a wing with supersonic curved leading edges is treated. Gives results for wings of small finite thickness at zero incidence. For calculations for wings in which the effective incidence varies as the chordwise or spanwise coordinates, the conception of conical fields of different order than that used for constant incidence is introduced.

Department of Supply (Australia)
AN INVESTIGATION INTO ENGINE WEAR CAUSED BY DUST. R. V. Pavia. July 1950. 19p. diagrs., photos., 5 tabs. (Department of Supply. ACA-50)

A number of wear tests have been made on an R.1830 Twin Wasp single-cylinder engine with dust introduced into the intake air, to study the effects on engine wear of dust quantity, dust concentration, and dust size. The results show that generally the wear is proportional to the weight of dust fed, but the amount of wear produced by a given weight of dust decreases as the dust concentration increases. Maximum wear was obtained with a dust size of about 15 microns, while the wear with 100-micron dust was only half as much. A simple method, which agrees well with the experimental results, has been suggested for estimating the wear caused by a mixture of dusts with known individual wear characteristics.

N-3136*

INFLUENCE OF THE FLUID BOUNDARIES ON THE LONGITUDINAL STABILITY OF BODIES. (Der einfluss von flussigkeitsgrenzen auf die langsstabilität von körpern). W. Albring. August 1951. 12p. diagrs. (Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. UM 6407, July 14, 1944).

Reports ideas on the problem of "nose-down tendency" of submarines near the surface. A marked increase in displacement at the nose has an adverse effect. If a hydrodynamically unfavorable shape is dictated by the purpose of application, the possibility of balance by a properly designed tail surface may still remain. This is confirmed by the derivation of stability equations. From these, a few rules have been derived for design. Researchers must determine the magnitude of interference by experiment.

N-9888*

ON THE USE OF LIGHT GASES FOR CLOSED-CYCLE HEAT ENGINES. (Uber die Verwendung von leichten Gasen für Wärmekraftmaschinen mit geschlossenem Kreislauf). J. Ackeret. 8p. diagr. (Trans. from Schweizerische Bauzeitung, v.127, 1946, p.51-52).

Although the conventional operating medium for closed-cycle heat engines is air, it should be of interest to see whether further progress could be achieved by the use of other gases. This report discusses the most essential points, but leaves out a number of problems, especially those of the operation. It is noted that for the cycle efficiency, without consideration of the temperature and pressure losses, the nature of the gas plays no part. It is assumed that only gases and gas mixtures of the same atomic structure are employed.

N-10759*

THE INTERFERENCE EFFECT OF A WIND TUNNEL WITH MIXED CONTOUR. (Sull'interferenza di una Galleria Aerodinamica a Contorno Misto). Enrico Pistolesi. August 1951. 33p. diagrs. (Trans. from Pontificia Accademia delle Scienze, Commentationes, v.7, no.5, p.75-100).

This report deals with the case in which the free vortex system of the wing is formed by a couple of concentric vortices or by a continuous distribution of vortices. The development is limited so that the formulas retain their generalities. The results are applied to two specific cases: (1) circulation constant along the span, and (2) elliptic circulation distribution.

HORIZONTAL TAIL LOADS IN MANEUVERING FLIGHT. Henry A. Pearson, William A. McGowan and James J. Donegan. 1951. ii, 12p. diagrs., 2 tabs. (NACA Rept. 1007. Formerly TN 2078)

A method is derived for determining the horizontal tail load following a prescribed maneuver. The tail load is broken down into various components which are examined to determine the maximum values. The method is extended to include suggestions for distributing the load across the span as well as in a chordwise direction. Equations are given for determining the maximum possible pitching angular velocity and pitching acceleration in a pull-up maneuver.

NACA TN 2451

MATHEMATICAL IMPROVEMENT OF METHOD FOR COMPUTING POISSON INTEGRALS INVOLVED IN DETERMINATION OF VELOCITY DISTRIBUTION ON AIRFOILS. I. Flügge-Lotz, Stanford University. October 1951. 84p. diagrs., 3 tabs. (NACA TN 2451)

A solution is presented of the Poisson integral involved in the determination of the change in velocity distribution resulting from a change in airfoil profile in parallel incompressible flow. Three well developed numerical methods of evaluating this integral, all based on the division of the range of integration into small equal intervals, and the difficulties involved in each method, are discussed. A new method based on the use of unequal intervals, is developed and compared with the other methods by means of several examples.

NACA TN 2465

EXPERIMENTAL AERODYNAMIC DERIVATIVES OF A SINUSOIDALLY OSCILLATING AIRFOIL IN TWO-DIMENSIONAL FLOW. Robert L. Halfman, Massachusetts Institute of Technology. November 1951. 83p. diagrs., photo., 19 tabs. (NACA TN 2465)

Experimental measurements of the aerodynamic reactions on a symmetrical airfoil oscillating harmonically in a two-dimensional flow are presented and analyzed. Harmonic motions include pure pitch and pure translation, for several amplitudes and superimposed on an initial angle of attack, as well as combined pitch and translation. Considerable consistent data for pure pitch were obtained from a search of available reference material, and several definite Reynolds number effects are evident.

NACA TN 2473

ON THE SPECTRUM OF ISOTROPIC TURBULENCE. H. W. Liepmann, J. Laufer and Kate Liepmann, California Institute of Technology. November 1951. 61p. diagrs. (NACA TN 2473)

Measurements of the spectrum and correlation functions at large Reynolds numbers were made, as well as a series of accurate spectrum measurements at lower Reynolds numbers, and the results are compared with theory. The second, fourth, and sixth moments of the spectrum were computed from the measurements and are discussed in relation to theoretical results. The significance of the number of zeros of the fluctuating velocity components was investigated and examples of measurements for the determination of the microscale of turbulence from zero counts are presented.

NACA TN 2493

ANALYSIS OF AN AXIAL COMPRESSOR STAGE WITH INFINITESIMAL AND FINITE BLADE SPACING. H. J. Reissner and L. Meyerhoff, Polytechnic Institute of Brooklyn. October 1951. 32p. diagrs. (NACA TN 2493)

A method of designing circular blade systems of finite spacing is developed. First, the theory of flow through a system of infinitesimally spaced surfaces is formulated by means of a continuous axially symmetric force field which is uniform in the circumferential direction. This force field replaces the effect of the blade system, with its hub and shroud boundary surfaces. Second, the force field in the space between the blades, hub, and shroud is replaced in the equations of finite spacing by inertia and pressure terms, which were omitted in equations of infinitesimal spacing. These terms will change values of flow variables of infinitesimal spacing.

NACA TN 2495

WIND-TUNNEL INVESTIGATION OF EFFECTS OF VARIOUS AERODYNAMIC BALANCE SHAPES AND SWEEPBACK ON CONTROL-SURFACE CHARACTERISTICS OF SEMISPAN TAIL SURFACES WITH NACA 0009, 0015, 66-009, 66(215)-014, AND CIRCULAR-ARC AIRFOIL SECTIONS. John J. Harper, Georgia Institute of Technology. October 1951. 127p. diagrs., photos., 5 tabs. (NACA TN 2495)

A summary of force data on unswept and sweptback airplane control surfaces is presented. Lift and hinge-moment characteristics were determined for

four unswept, semispan control surfaces, and lift, drag, hinge moment, and pitching moment were determined for two semispan, sweptback control surfaces. These control surfaces were of the wide-chord type suitable for use as elevators or rudders. Measured values of the various parameters are compared with those obtained from section data by application of lifting-surface and lifting-line theory.

NACA TN 2503

HYDRODYNAMIC INVESTIGATION OF A SERIES OF HULL MODELS SUITABLE FOR SMALL FLYING BOATS AND AMPHIBIANS. W. C. Hugli, Jr. and W. C. Axt, Stevens Institute of Technology. November 1951. 122p. diagrs., photos., 4 tabs. (NACA TN 2503)

Results of an investigation to obtain hydrodynamic information on a series of hull models suitable for small flying boats or amphibians of from 2000 to 5000 pounds gross weight are presented. The series of hulls consisted of a basic hull with simple lines with plus or minus variations to this design in which the beam, sternpost angle, and afterbody length were altered. Modifications were also investigated to determine the advantage of refining the hull lines. The hulls were tested for hydrodynamic resistance and main spray. On the basis of these characteristics, the best beam and sternpost angle were selected for each of the three afterbody lengths investigated. The resulting three hulls were further tested for landing and porpoising characteristics.

NACA TN 2512

STRESSES IN A TWO-BAY NONCIRCULAR CYLINDER UNDER TRANSVERSE LOADS. George E. Griffith. October 1951. 34p. diagrs., 3 tabs. (NACA TN 2512)

A method, taking into account the effects of flexibility and based on a general eighth-order differential equation, is presented for finding the stresses in a two-bay, noncircular cylinder the cross section of which can be composed of circular arcs. Numerical examples are given for two cases of ring flexibility for a cylinder of doubly symmetrical (essentially elliptic) cross section, subjected to concentrated radial, moment, and tangential loads. The results parallel those already obtained for shells with circular rings.

NACA TN 2514

RELATIVE STRUCTURAL EFFICIENCIES OF FLAT BALSA-CORE SANDWICH AND STIFFENED-PANEL CONSTRUCTION. Ralph E. Hubka, Norris F. Dow and Paul Seide. October 1951. 29p. diagrs. (NACA TN 2514)

An analysis is made and charts are presented for the determination of regions of efficient application of flat balsa-core sandwich and stiffened-panel construction for a large range of design requirements. Optimum sandwiches were found to have relatively low values of the ratio of core thickness to face thickness.

NACA TN 2515

THE LINEARIZED CHARACTERISTICS METHOD AND ITS APPLICATION TO PRACTICAL NON-LINEAR SUPERSONIC PROBLEMS. Antonio Ferri. October 1951. 65p. diagrs. (NACA TN 2515)

The method of characteristics has been linearized by assuming that the flow field can be represented as a basic flow field determined by nonlinearized methods and a linearized superposed flow field that considers small changes in boundary conditions. The method has been applied to two-dimensional rotational flow, to calculations of axially symmetric flow, to slender bodies without symmetry, and to wing problems.

NACA TN 2516

A SURVEY OF CREEP IN METALS. A. D. Schwope and L. R. Jackson, Battelle Memorial Institute. November 1951. 66p. diagrs., tab. (NACA TN 2516)

This report summarizes numerous theories relating to creep phenomena and the extent of current knowledge on the subject. Various possible mechanisms by which creep occurs both in single crystals and in polycrystals are described. An extensive bibliography of published works in this field is also included.

NACA TN 2522

A GRAPHICAL METHOD FOR PLOTTING AMPLITUDE AND PHASE ANGLE OF TRANSFER FUNCTIONS OF DYNAMIC SYSTEMS WITHOUT FACTORING POLYNOMIALS. Earl F. Smith. November 1951. 35p. diagrs., 4 tabs. (NACA TN 2522)

A method is presented for obtaining amplitude and angle plots for rational algebraic functions of an imaginary variable. The method involves the use of templets but does not require the factoring of polynomials. Application of the method is illustrated by by an example in which the frequency response of an aircraft and automatic control system is plotted.

NACA TN 2523

ROTOGENERATIVE DETECTION OF CORROSION CURRENTS. Joseph B. McAndrew, William H. Colner and Howard T. Francis, Armour Research Foundation. November 1951. 12p. photos., diagrs. (NACA TN 2523)

A new technique for studying corrosion phenomena is described which permits the detection of the presence of currents produced by local cells on the surface of a corroding metal specimen. A cylindrical specimen is rotated at several hundred revolutions per minute in the corrosion medium. A small reference electrode is positioned as near the specimen as possible, thus scanning the surface of the metal. The signal produced is amplified and applied to an oscilloscope, together with a suitably synchronized sweep voltage. A standing pattern is produced on the oscilloscope which is a reproduction of the potential fields set up in the corrosion medium by the currents flowing between the elements of local cells.

NACA TN 2524

AN INVESTIGATION OF AIRCRAFT HEATERS. XXXVIII - DETERMINATION OF THERMAL PERFORMANCE OF RECTANGULAR- AND TRAPEZOIDAL-SHAPED INNER-SKIN PASSAGES FOR ANTI-ICING SYSTEMS. L. M. K. Boelter, V. D. Sanders and F. E. Romie, University of California. November 1951. 21p. diagrs., photos. (NACA TN 2524)

An investigation was conducted to determine the thermal and hydrodynamic behavior of air in the downstream portion of two types of double-skin passages used in heated-air leading-edge anti-icing systems. The downstream average unit thermal conductance in the turbulent region was 30 to 35 percent below that given by the commonly used equations. In the laminar region, the experimental unit conductance was about 30 percent below the predicted values for rectangular ducts but for trapezoidal ducts the data were much lower than the predicted values.

NACA TN 2525

THE EFFECT OF RATE OF CHANGE OF ANGLE OF ATTACK ON THE MAXIMUM LIFT COEFFICIENT OF A PURSUIT AIRPLANE. Burnett L. Gadeberg. October 1951. 17p. diagrs., photo. (NACA TN 2525. Formerly RM A8I30)

Flight tests have been made with a pursuit airplane to determine the effect of Mach and Reynolds numbers on the variation of the rate of change of maximum lift coefficient with rate of change of angle of attack. These tests have indicated that the rate of increase of maximum lift coefficient with increasing abruptness of the stall is significantly affected by Reynolds number as well as Mach number. Both parameters reduce this rate of increase over the lower ranges tested and increase it in the higher ranges.

NACA TN 2528

A METHOD FOR PREDICTING THE UPWASH ANGLES INDUCED AT THE PROPELLER PLANE OF A COMBINATION OF BODIES WITH AN UNSWEPT WING. Paul F. Yaggy. October 1951. 24p. diagrs., photos. (NACA TN 2528)

An approximate method for predicting the upwash angles induced at the horizontal center line of the propeller disk of a twin-engine airplane is developed and is shown to be satisfactory. The applicability of the method to other airplanes is discussed.

NACA TN 2529

SECONDARY STRESSES IN THIN-WALLED BEAMS WITH CLOSED CROSS SECTIONS. Stanley Urner Benscoter, California Institute of Technology. October 1951. 104p. diagrs. (NACA TN 2529)

An accurate method of determining secondary stresses in thin-walled, uniform beams of closed cross section is presented. The cross sections are assumed to be preserved by closely spaced rigid diaphragms. In the first section of the paper the integrodifferential equation governing axial displacements is formulated and solved for a beam without longitudinal stiffeners. In the second section of the paper the corresponding summation-difference equation is developed and solved for a beam with stiffeners (flanges and stringers). The cross section, loading distribution, and end conditions are assumed to be arbitrary.

NACA TN 2531
National Advisory Committee for Aeronautics.
SIMPLIFIED METHOD FOR CALCULATION OF COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH ARBITRARY FREE-STREAM PRESSURE GRADIENT. George M. Low. October 1951. 28p. diagrs., 2 tabs. (NACA TN 2531)

The Kármán-Polhausen method, as applied to compressible laminar boundary layers, is simplified by an analysis similar to the incompressible Holstein-Bohlen method. The analysis is carried out under the assumptions of a Prandtl number of 1, zero heat transfer, and a linear viscosity-temperature relation. Results are presented so that velocity and temperature profiles, momentum and displacement thicknesses, and wall shear stress can be calculated for flows over two-dimensional bodies with arbitrary free-stream velocity distributions. The results are also applicable to flows over three-dimensional bodies with axial symmetry through the use of Mangler's transformation.

NACA TN 2532
National Advisory Committee for Aeronautics.
X-RAY DIFFRACTION STUDY OF THE INTERNAL STRUCTURE OF SUPERCOOLED WATER. Robert G. Dorsch and Bemrose Boyd. October 1951. 14p. diagrs., photo. (NACA TN 2532)

X-ray diffraction data for water in the temperature range 21° to -16° C are presented. The minimum between the two main diffraction peaks deepened continuously, as the temperature was lowered. It is concluded that supercooled water apparently becomes progressively more ice-like in structure as the temperature is lowered.

NACA TN 2535
National Advisory Committee for Aeronautics.
MINIMUM WAVE DRAG OF BODIES OF REVOLUTION WITH A CYLINDRICAL CENTER SECTION. Franklyn B. Fuller and Benjamin R. Briggs. October 1951. 34p. diagrs. (NACA TN 2535)

The minimum wave-drag problem with auxiliary conditions is solved for axial flow about bodies of revolution consisting of two symmetrical ogival sections joined by a circular cylinder. The auxiliary conditions are that the total length, the length of the cylinder, the frontal area, and the volume are held constant. The results are related to similar results known for bodies of revolution without a cylindrical midsection, and it is found that the addition of small amounts of center section has little effect on the drag. The maximum thickness ratio leading to the least total of wave and friction drag is investigated briefly.

NACA TN 2545

DISCREPANCIES BETWEEN THEORETICAL AND OBSERVED BEHAVIOR OF CYCLICALLY LOADED BEARINGS. R. W. Dayton, E. M. Simons and F. A. Fend, Battelle Memorial Institute. November 1951. 27p. diagrs., photos. (NACA TN 2545)

Discrepancies between theory and the experimental behavior of a cyclically loaded shaft rotating in a sleeve bearing are analyzed. For constant loads rotating at one-half the frequency of shaft rotation, eccentricity ratios were found to be unity when kerosene was used to lubricate the test bearing. This agrees with theoretical predictions. However, when SAE 10 oil was used, the eccentricity ratios were reduced. Under the latter conditions, the eccentricity ratio decreased as the shaft speed increased. Refinements of the test conditions resulted in observed eccentricity ratios which were closer to the theoretically predicted value of unity.

NACA RM E51H31

A MULTIPLE-RANGE SELF-BALANCING THERMOCOUPLE POTENTIOMETER. I. Warshawsky and M. Estrin. November 1951. 15p. diagrs., photo., 2 tabs. (NACA RM E51H31)

A multiple-range potentiometer circuit is described that provides automatic measurement of temperatures or temperature differences with any one of several thermocouple-material pairs. Techniques of automatic reference-junction compensation, span adjustment, and zero suppression are described that permit rapid selection of range and wire material, without the necessity for restandardization, by setting of two external tap switches.

NACA TM 1308

ON MOTION OF FLUID IN BOUNDARY LAYER NEAR LINE OF INTERSECTION OF TWO PLANES. (O Dvizhenii Zhidkosti v Pogranichnom Sloe Vblizi Linii Peresechenia Dvukh Ploskostei). L. G. Loitsianskii and V. P. Bolshakov. November 1951. 27p. diagrs., 4 tabs. (NACA TM 1308. Trans. from Central Aero-Hydrodynamical Institute, Transactions, Rept.279, 1936, p.3-18).

A motion of a slightly viscous incompressible fluid that flows between two semi-infinite planes which intersect at an angle between 0° and 180° is discussed. The increase in thickness of the boundary layer near the line of intersection of the two planes, the limits of the effect of the corner, and the effect on the drag are determined. The analysis is made for both laminar and turbulent flow by using the momentum theorem and assuming suitable velocity profiles.

NACA TM 1309

ON THE THEORY OF THIN AND THIN-WALLED RODS. (K. Teorii Tonkikh i Tonkostennykh Sterzhnei). G. Y. Dzhanelidze. October 1951. 18p. tab. (NACA TM 1309. Trans. from Prikladnaya Matematika i Mekhanika, v.13, Nov.-Dec.1949, p.597-608).

An approximate theory for the torsion and bending of thin shells is developed. The theory is based on two fundamental assumptions: cross sections are unstrained in their own planes, and the longitudinal strain in the cross section can be represented by a planar distribution (the usual engineering assumption) and by a distribution proportional to the St. Venant warping. The torsion and bending problems are discussed in the light of these assumptions; the analysis is then applied to the free vibration of a thin shell in combined torsion and bending.

NACA TM 1311

CONTRIBUTIONS TO THE THEORY OF THE SPREADING OF A FREE JET ISSUING FROM A NOZZLE. (Zur Theorie der Ausbreitung eines aus einer Düse austretenden freien Strahls). W. Szablewski. November 1951. 72p. diagrs. (NACA TM 1311. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. UM 8003, September 1944).

For the flow field of a free jet leaving a nozzle of circular cross section in a medium with straight uniform flow field, approximate formulas are presented for the calculation of the velocity distribution and the dimensions of the core region. The agreement with experimental results is satisfactory.

NACA TM 1320

INVESTIGATIONS ON WINGS WITH AND WITHOUT SWEEPBACK AT HIGH SUBSONIC SPEEDS. (Untersuchungen an gepfeilten und ungepfeilten Flügeln bei hohen Unterschallgeschwindigkeiten). Jakob Ackeret, Max Degen and Nikolaus Rott. November 1951. 14p. diagrs., photos. (NACA TM 1320. Trans. from Zeitschrift für angewandte Mathematik und Physik, v.1, 1950, p.32-42).

Drag tests at zero lift have been made at Mach numbers from 0.7 to approximately 0.95 in the high speed wind tunnel of the Institute for Aerodynamics, ETH, Zürich, on a group of untapered wings of aspect ratio 3.25, having sweep angles of 0° and 35°. For each sweep angle, a series of geometrically similar models was tested at a constant Reynolds number to provide a verification of computed tunnel blocking corrections. Tests were also made for wings having thickness ratios of 0.09 and 0.12 and the results compared with results predicted by von Kármán's similarity law.

NACA TM 1323

INFLUENCE OF STATIC LONGITUDINAL STABILITY ON THE BEHAVIOR OF AIRPLANES IN GUSTS. (Einfluss der statischen Längsstabilität auf das Verhalten eines Flugzeuges in Böen). H. Hoene. November 1951. 26p. diagrs. (NACA TM 1323. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1422, December 31, 1940).

The equations of motion for an airplane penetrating a gust are derived using a few simplifying assumptions. Calculations of loads for different static longitudinal stability on two German airplane models,

HC 45 and HS 122, are compared with flight tests. Good agreement is obtained between the trend of the flight tests and the calculated values; however no absolute comparison was possible between the flight tests and calculations.

Department of Supply (Australia)
CORROSION OF METALS. METALS UNDER STRESS: I. ALUMINIUM. P. F. Thompson. July 1950. 22p. photos., diagrs. (Department of Supply. ACA-49)

Discusses the corrosion of aluminum under stress. Gives time-potential curves determined simultaneously of stressed and unstressed electrodes of commercially pure aluminum. Test pieces of various shapes were used. Determinations were made in various liquids, including distilled water, tap water, salt solutions and sea water; and so that full assessment of the oxidizing potentials could be made, these solutions were examined under full aeration and under complete deaeration. The conclusions following on the work of this report indicate that stresses are but contributory factors in the so-called process of "stress-corrosion."

OBSERVATION OF THE LUBRICATING OIL FILM BETWEEN PISTON RING AND CYLINDER OF A RUNNING ENGINE. THE EFFECT OF RING GEOMETRY. R. L. Brooks and M. L. Atkin. November 1950. 13p. diagrs., photos. (Department of Supply. ACA-52)

The effect of ring geometry on lubrication between the top piston ring and cylinder wall of a single cylinder aircraft engine was studied by measuring the electrical contact resistance. Torsion rings gave better results than square section rings of corresponding designs. Tapered leading edges were effective in promoting the rapid formation and maintenance of an oil film. Chamfered edges did not effect any improvement. Rings which were tapered across the full bearing faces gave traces which had a sawtooth appearance, with severe breakdowns at the bottom centers. Two piston ring designs which might give improved performance have been suggested.

THE LIFT DISTRIBUTION OVER THE WINGS OF AN AIRPLANE I - SPANWISE LIFT DISTRIBUTION. (La Distribuzione della Portanza sulla Velatura di un Valivolo. I - La Distribuzione della Portanza sull'apertura). Enrico Pistolesi. August 1951. 92p. diagrs. (Trans. from Annali del Registro Aeronautico Italiano, v. 3, no.3, September 1942. 80p.)

Presents a review of methods of calculating the spanwise lift distribution over the wings of an airplane. Includes methods producing quick, and reasonably approximate solutions by simple means, including those obtained by an elaboration in diagrams and tables from one of the theoretical methods. Gives a brief summary of special wing theories, as distinct from Prandtl's simple line vortex, which can be used for the theoretical calculation of the lift distribution along the span as well as along the chord.

CURRENT NACA REPORTS

NACA TN 2530

WIND-TUNNEL INVESTIGATION OF SIX SHIELDED TOTAL-PRESSURE TUBES AT HIGH ANGLES OF ATTACK. SUBSONIC SPEEDS. Walter R. Russell, William Gracey, William Letko and Paul G. Fournier. November 1951. 25p. diagrs., tab. (NACA TN 2530)

Calibrations of six shielded total-pressure tubes over an angle-of-attack range of -30° to 65° at Mach numbers of 0.26, 0.50, 0.70, 0.90, and 0.95 are presented. One of these tubes was a standard Kiel design, while the other tubes were variations of this design. The design variables which were investigated included the shape of the venturi entry (conical and curved), the position of the total-pressure probe with respect to the leading edge of the shield, the internal diameter of the shield, and the shape of the leading-edge profile. The effect of these variables on the range of angle of attack over which the tubes remained insensitive to inclination is discussed.

NACA TN 2533

EVALUATION OF HIGH-ANGLE-OF-ATTACK AERODYNAMIC-DERIVATIVE DATA AND STALL-FLUTTER PREDICTION TECHNIQUES. Robert L. Halfman, H. C. Johnson and S. M. Haley, Massachusetts Institute of Technology. November 1951. 154p. diagrs., photos., 11 tabs. (NACA TN 2533)

The aerodynamic reactions on wings oscillating harmonically in pitch and translation in the stall range have been measured, evaluated, and correlated where possible with available published data. Data on the time-average values in the stall range of both lift and moment are presented. The results of numerous experimental observations of stall flutter have been reviewed and known attempts at its prediction have been examined, compared, and extended. A semi-empirical method of predicting the variations of moment in pitch with airfoil shape, reduced frequency, initial angle of attack, and amplitude of oscillation has been presented.

NACA TN 2534

EXPERIMENTAL INVESTIGATION OF THE LOW-SPEED STATIC AND YAWING STABILITY CHARACTERISTICS OF A 45° SWEPTBACK HIGH-WING CONFIGURATION WITH VARIOUS TWIN VERTICAL WING FINS. Alex Goodman and Walter D. Wolhart. November 1951. 25p. diagrs., photos., 3 tabs. (NACA TN 2534)

Results are presented of an investigation of the low-speed static and yawing stability characteristics of a 45° sweptback high-wing, low-horizontal-tail configuration with various twin vertical fins located on the wing. The static and yawing stability characteristics obtained with the various twin-fin configurations are compared with the characteristics of a similiar configuration with a single vertical tail at the rear of the fuselage. In addition, the effects of a small vertical fin at the rear of the fuselage on the characteristics of the twin-fin configurations are presented.

NACA TN 2539

APPLICATION OF VARIATIONAL METHODS TO TRANSONIC FLOWS WITH SHOCK WAVES. Chi-Teh Wang and Pei-Chi Chou, New York University. November 1951. 32p. diagrs., 4 tabs. (NACA TN 2539)

By modifying Bateman's variational principle for irrotational flows, it is shown that a variational principle for flows with rotation and variable entropy can be obtained. By applying this variational principle to the regions of flow behind shock waves and Bateman's original principle to the other regions in the fluid, shock equations can be directly obtained. A procedure for computing numerical solutions for such flows is suggested, and a numerical example is carried out. The results show that when the Mach number increases to a certain limiting value without allowing for shock waves the variational method does not have a solution. This probably indicates the breakdown of the irrotational flow. By allowing shock waves to occur, solution again exists.

NACA TN 2540

APPLICATION OF RESPONSE FUNCTION TO CALCULATION OF FLUTTER CHARACTERISTICS OF A WING CARRYING CONCENTRATED MASSES. H. Serbin and E. L. Costilow, Purdue University. November 1951. 52p. diagrs., 3 tabs. (NACA TN 2540)

Concepts involved in the harmonic-response-function method, such as the direct or conjugate characteristic modes, are illustrated by application of the method to the calculation of the change in flutter characteristics of a wing due to adding concentrated masses. The rigid body is first idealized as a point mass, then as a distributed mass. The main purpose of the numerical procedures which are given is to illustrate the scope of the method and to make some of its abstract formulations more specific. An appendix is given which contains some of the essential theoretical background.

NACA TN 2541

STUDIES OF VON KÁRMÁN'S SIMILARITY THEORY AND ITS EXTENSION TO COMPRESSIBLE FLOWS. A CRITICAL EXAMINATION OF SIMILARITY THEORY FOR INCOMPRESSIBLE FLOWS. C. C. Lin and S. F. Shen, Massachusetts Institute of Technology. November 1951. 24p. (NACA TN 2541)

Von Kármán's similarity theory for incompressible flows is examined critically by using modern concepts in order to provide a basis for extending the theory to compressible flows. It is found that the original form of the theory is supported by modern concepts.

NACA TN 2544

HYDRODYNAMIC LUBRICATION OF CYCLICALLY LOADED BEARINGS. R. W. Dayton and E. M. Simons, Battelle Memorial Institute. November 1951. 76p. diagrs., photos. (NACA TN 2544)

Results are presented of an experimental investigation conducted in order to check the validity of analytical studies of simple cases of cyclic loading and to determine the effect of the loading conditions on hydrodynamic lubrication when the load diagram is so complex that analytical treatment is difficult or impossible. A precise test bearing was set up to which constant or varying unidirectional loads or constant rotating loads could be applied, singly or together, and the effect of the load diagram on hydrodynamic lubrication was measured from the attitude of the journal in the bearing.

NACA TN 2546

VISCOSITIES OF AIR AND NITROGEN AT LOW PRESSURES. Herrick L. Johnston, Robert W. Mattox and Robert W. Powers, Ohio State University. November 1951. 22p. diagrs., 6 tabs. (NACA TN 2546)

Information is presented of the results of an investigation to measure the viscosities of nitrogen and air at 306° and 273° K at pressures from 500 to 0.0005 millimeter of mercury and at 194° and 79° K at pressures down to 0.3 millimeter of mercury.

NACA TN 2555

National Gas Turbine Establishment (Gt. Brit.)
A NOTE ON RADIATION HEAT TRANSFER. G. A. E. Godsave. March 1951. 21p. diagrs. (NGTE Memo. M.111)

The majority of previous discussions of radiation heat transfer between surfaces have been restricted to the case where the surfaces are considered to be grey and opaque. In this paper the case of interchange of radiation between surfaces that may partly absorb, reflect and transmit the incident radiation is considered. The surfaces are considered to be selective emitters. Expressions for calculating radiation heat transfer under these conditions are derived in particular for parallel plane surfaces, concentric spherical surfaces and concentric cylindrical surfaces. Both regularly reflecting and diffusely reflecting surfaces are discussed. For the special case of grey opaque surfaces these expressions all reduce to those previously published by other authors for this case.

COMPUTATION OF ONE-DIMENSIONAL GAS FLOWS. (Raschet odnoragmernik gazovik techenii). B. M. Kiselev. 29p. diagrs. (Trans. from Prikladnaia Matematika i Mekhanika, v.11, 1947, p.177-192).

Problems of one-dimensional gas flow are solved by means of three equations: the equation of continuity or conservation of mass, the equation of mechanics, and the equation of energy. In a number of papers, the solution is considerably simplified by the application of the initial or stagnation parameters p_0, ρ_0, and T_0, and the introduction of the nondimensional velocity $\lambda = W/a$. The solution of the problems can be still further simplified if these equations are applied in a somewhat modified form. In the present paper, the transformed equations of gas dynamics are given and the effectiveness of the application of these equations is illustrated with the aid of a number of examples. The computation of an ejector is considered in greater detail.

FLEXURAL FATIGUE STRENGTHS OF RIVETED BOX BEAMS - ALCLAD 14S-T6, ALCLAD 75S-T6, AND VARIOUS TEMPERS OF ALCLAD 24S. I. D. Eaton and Marshall Holt. Aluminum Company of America. November 1951. 25p. diagrs., photos., 3 tabs. (NACA TN 2452)

Results are given of tests made to determine and compare the flexural fatigue strengths of built-up riveted box beams made from 14S-T6, 75S-T6, and various tempers of 24S alclad aluminum-alloy sheet.

NACA TN 2482

STABILITY AND CONTROL CHARACTERISTICS OF A COMPLETE AIRPLANE MODEL HAVING A WING WITH QUARTER-CHORD LINE SWEPT BACK 40°, ASPECT RATIO 2.50, AND TAPER RATIO 0.42. Marvin Schuldenfrei, Paul Comisarow and Kenneth W. Goodson. December 1951. 86p. photos., diagrs. (NACA TN 2482. Formerly RM L7B25)

An investigation has been made of a complete airplane model having a wing with the quarter-chord line swept back 40°, aspect ratio 2.50, and taper ratio 0.42 to determine its low-speed stability and control characteristics. The longitudinal stability investigation included stabilizer and tail-off tests with different wing dihedral angles ($\Gamma = 0^\circ$ and $\Gamma = -10^\circ$) over an angle-of-attack range for the cruising and landing configurations and tests with a high horizontal-tail location ($\Gamma = -10^\circ$) for the cruising configuration. Tests were made of the wing alone and to determine the effect of wing end plates in pitch. Lateral stability characteristics were determined for the airplane with different geometric wing dihedrals, with end plates, and with several dorsal modifications. Tests were made with ailerons and spoilers to determine control characteristics.

NACA TN 2518

CRITERIONS FOR CONDENSATION-FREE FLOW IN SUPERSONIC TUNNELS. Warren C. Burgess, Jr. and Ferris L. Seashore. December 1951. 39p. diagrs., photos., tab. (NACA TN 2518. Formerly RM E9E02)

The results of an investigation of water-vapor condensation shocks in the air passing through supersonic tunnels are presented. Criterions for condensation free flow are established by correlating experimental observations with the Volmer theory of nuclei formation. Experimental observations were made at Mach numbers up to 2.01. The criterions are presented in a form independent of tunnel-inlet stagnation pressure and are extended theoretically to a Mach number of 4.0. Preliminary evidence of the effect of tunnel size on the criterions is presented.

NACA TN 2527

A VELOCITY-CORRECTION FORMULA FOR THE CALCULATION OF TRANSONIC MACH NUMBER DISTRIBUTIONS OVER DIAMOND-SHAPED AIRFOILS. H. Reese Ivey and Keith C. Harder. November 1951. 28p. diagrs. (NACA TN 2527)

A velocity-correction formula is proposed for the purpose of calculating, from the known Mach number distribution for a diamond-shaped airfoil, at a stream Mach number of 1.0, Mach number distributions on the same airfoil at speeds from a Mach number of about 0.8 to shock-attachment Mach number. An expression for the rate of change of local Mach number with stream Mach number is derived and an explicit equation for the drag coefficient as a function of stream Mach number and thickness ratio is given.

NACA TN 2536

CRITICAL COMBINATIONS OF BENDING, SHEAR, AND TRANSVERSE COMPRESSIVE STRESSES FOR BUCKLING OF INFINITELY LONG FLAT PLATES. Aldie E. Johnson, Jr. and Kenneth P. Buchert. December 1951. 40p. diagrs., 3 tabs. (NACA TN 2536)

Three-dimensional interaction surfaces are presented for the computation of elastic buckling stresses for an infinitely long flat plate subjected to combinations of bending, shear, and transverse compression in its plane - a loading approximating that occurring in a shear web. Surfaces are presented for two sets of edge conditions: both edges simply supported, and lower edge simply supported, upper edge clamped. Present results are in good agreement with data for one-load and two-load limiting cases previously published.

NACA TN 2537

HEAT CAPACITY LAG IN GASES. Richard Walker, Iowa State College. November 1951. 40p. diagrs., tab. (NACA TN 2537)

A review is presented of the literature on the sonic studies of the problem of the excitation of molecular vibrations by collision and the theory on which the interpretation of almost all the sonic work has been based is discussed. The principal experimental programs are described and most of the available results are included in a table.

NACA TN 2542

STUDIES OF VON KÁRMÁN'S SIMILARITY THEORY AND ITS EXTENSION TO COMPRESSIBLE FLOWS. A SIMILARITY THEORY FOR TURBULENT BOUNDARY LAYER OVER A FLAT PLATE IN COMPRESSIBLE FLOW. C. C. Lin and S. F. Shen, Massachusetts Institute of Technology. November 1951. 37p. (NACA TN 2542)

As an application of the concepts in NACA TN 2541, the problem of turbulent boundary layer over a flat plate in compressible flow is treated. The dissipation term in the energy equation, usually neglected, is first studied and found to be of importance. In the differential equations governing the fluctuations, the lower-frequency components of all quantities are regarded to participate in an equilibrium in accordance with similarity. After proper linearization, a set of differential equations containing only the lower order frequency fluctuations is obtained. In parallel with Von Kármán's theory in incompressible flow, similarity scales for all the flow variables are derived. Two possible length scales are found and the significance of this possibility is discussed.

NACA TN 2543

STUDIES OF VON KÁRMÁN'S SIMILARITY THEORY AND ITS EXTENSION TO COMPRESSIBLE FLOWS. INVESTIGATION OF TURBULENT BOUNDARY LAYER OVER A FLAT PLATE IN COMPRESSIBLE FLOW BY THE SIMILARITY THEORY. S. F. Shen, Massachusetts Institute of Technology. November 1951. 43p. (NACA TN 2543)

The turbulent-boundary-layer flow over a flat plate in compressible flow is considered on the basis of the scheme established in NACA TN 2542. It is shown how the influence of the Mach number (e.g., on the velocity and temperature distribution) can be predicted from the theory after the constant coefficients in the theory are determined by one set of experimental measurements.

NACA TN 2547

AN INVESTIGATION BY THE HODOGRAPH METHOD OF FLOW THROUGH A SYMMETRICAL NOZZLE WITH LOCALLY SUPERSONIC REGIONS. F. Edward Ehlers and Hirsh G. Cohen, Brown University. November 1951. 61p. diagrs., 2 tabs. (NACA TN 2547)

To study the flow of a compressible fluid through a channel having locally supersonic regions, the Tricomi equation is used in the hodograph variables as an approximation in the sonic region to the equation of flow of an irrotational, inviscid gas. A one-parameter family of solutions of the Tricomi equation is used which provides symmetrical accelerated-decelerated flows. Variation of this parameter alters the Mach number at the center of the throat, the velocity distribution and gradient along the center streamline, as well as the shape of the channel, that is the curvature of the bounding streamline. Other solutions to the Tricomi equation are discussed which may be used to formulate channel flows.

NACA TN 2550

DETERMINATION OF SHAPES OF BOATTAIL BODIES OF REVOLUTION FOR MINIMUM WAVE DRAG. Mac C. Adams. November 1951. 20p. diagrs. (NACA TN 2550)

By use of an approximate equation for the wave drag of slender bodies of revolution in a supersonic flow field, the optimum shapes of certain boattail bodies are determined for minimum wave drag. The properties of three specific families of bodies are determined, the first family consisting of bodies having a given length and base area and a contour passing through a prescribed point between the nose and base, the second family having fixed length, base area, and maximum area, and the third family having given length, volume, and base area.

NACA TN 2551

EFFECT OF VARIOUS PARAMETERS INCLUDING MACH NUMBER ON THE SINGLE-DEGREE-OF-FREEDOM FLUTTER OF A CONTROL SURFACE IN POTENTIAL FLOW. Harry L. Runyan. December 1951. 33p. diagrs. (NACA TN 2551)

Calculations demonstrating the existence of single-degree-of-freedom flutter of a control surface are presented. The effect of various parameters such as Mach number, aerodynamic balance, structural damping, and inertia ratio are shown. Even though the calculations are based on potential-flow theory, the results should provide a logical basis or framework with which to examine oscillations of a control surface believed due to separated flow phenomena.

NACA TN 2552

CONSIDERATIONS ON THE EFFECT OF WIND-TUNNEL WALLS ON OSCILLATING AIR FORCES FOR TWO-DIMENSIONAL SUBSONIC COMPRESSIBLE FLOW. Harry L. Runyan and Charles E. Watkins. December 1951. 18p. diagrs. (NACA TN 2552)

This paper treats the effect of wind-tunnel walls on the oscillating two-dimensional air forces in a compressible medium. The walls are simulated by the usual method of placing images at appropriate distances above and below the wing. An important result shown is that, for certain conditions of wing frequency, tunnel height, and Mach number, the tunnel and wing may form a resonant system so that the forces on the wing are greatly changed from the condition of no tunnel walls.

NACA TN 2554

THEORETICAL AERODYNAMIC CHARACTERISTICS OF A FAMILY OF SLENDER WING-TAIL-BODY COMBINATIONS. Harvard Lomax and Paul F. Byrd. November 1951. 75p. diagrs., 2 tabs. (NACA TN 2554)

The aerodynamic characteristics of an airplane configuration composed of a swept-back, nearly constant chord wing and a triangular tail mounted on a cylindrical body are presented. The analysis is based on the assumption that the free-stream Mach number is near unity or that the configuration is slender. The calculations for the tail are made on the assumption that the vortex system trailing back from the wing is either a sheet lying entirely in the plane of the flat tail surface or has completely "rolled up" into two point vortices that lie either in, above, or below the plane of the tail surface.

NACA TN 2557

INFRARED SPECTRA OF 59 DICYCLIC HYDROCARBONS. K. T. Serijan, I. A. Goodman and W. J. Yankauskas. November 1951. 37p. diagrs., 4 tabs. (NACA TN 2557)

The infrared spectra are presented for 59 dicyclic hydrocarbons consisting of some diphenylalkanes, dicyclohexylalkanes, alkylbiphenyls, and alkylbicyclohexyls ranging from C_{12} to C_{18}. The physical properties of these compounds, which were available in a high state of purity, are tabulated for reference purposes.

NACA TN 2558

SOME EFFECTS OF VARIATIONS IN SEVERAL PARAMETERS INCLUDING FLUID DENSITY ON THE FLUTTER SPEED OF LIGHT UNIFORM CANTILEVER WINGS. Donald S. Woolston and George E. Castile. December 1951. 40p. diagrs., 10 tabs. (NACA TN 2558)

An experimental investigation has been made of some effects of variations in several parameters, including fluid density, on the flutter characteristics of light uniform cantilever wings. Special emphasis has been placed on low values of the relative-density parameter $1/\sqrt{\kappa}$, where κ is the ratio of fluid density to wing mass. The experimental investigation has been supplemented by an analytical investigation. In general, the theoretical results followed the trends indicated by experiment except at low values of the relative density parameter and, in this region, additional analytical investigation seems necessary.

NACA TN 2559

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF CONDENSATION OF AIR IN HYPERSONIC WIND TUNNELS. H. Guyford Stever and Kenneth C. Rathbun, Massachusetts Institute of Technology. November 1951. 79p. diagrs., photos. (NACA TN 2559)

Presents results of theoretical and experimental investigation of condensation of air in hypersonic wind tunnels. The experimental work was done in a tunnel with Mach number of approximately 7. Condensation was detected and measured by condensation-fog light-scattering, static-pressure measurements, and changes in wedge shock angle at degrees of supersaturation considerably lower than those predicted by existing condensation theory. Effects of varying supply pressures and temperatures were also measured. The nucleation theory of condensation was modified to take account of a postulated variation of surface tension with decrease in size of spontaneously formed drops which act as nuclei of condensation. The modified theory was applied to pure oxygen and nitrogen and its predictions were compared with those of the unmodified theory.

NACA TN 2560

AN EXPERIMENTAL INVESTIGATION OF TRANSONIC FLOW PAST TWO-DIMENSIONAL WEDGE AND CIRCULAR-ARC SECTIONS USING A MACH-ZEHNDER INTERFEROMETER. Arthur Earl Bryson, Jr., California Institute of Technology. November 1951. 97p. diagrs., photos. (NACA TN 2560)

Interferometer measurements are given of the flow fields near two-dimensional wedge and circular-arc sections at zero angle of attack. Pressure distributions and drag coefficients as functions of Mach number were obtained and the wedge data are compared with theory. It is shown that the local Mach number at any point on the surface of a finite three dimensional body or an unswept two-dimensional body, moving through an infinite fluid, has a stationary value at Mach number 1 and, in fact, remains nearly constant for a range of speeds below and above Mach number 1. On the basis of this concept and the experimental data, pressure distributions and drag coefficients for the wedge and circular-arc sections are presented throughout the entire transonic range of velocities.

NACA TN 2562

NUMERICAL DETERMINATION OF INDICIAL LIFT OF TWO-DIMENSIONAL AIRFOILS AT SUBSONIC MACH NUMBERS FROM OSCILLATORY LIFT COEFFICIENTS WITH CALCULATIONS FOR MACH NUMBER 0.7. Bernard Mazelsky. December 1951. 38p. diagrs., tab. (NACA TN 2562)

The indicial lift and moment on an airfoil experiencing a sudden acquisition of vertical velocity is calculated for Mach number 0.7 from the available flutter coefficients for an oscillating airfoil. An approximate calculation is also made for the indicial-lift function due to penetration of a sharp-edged gust.

NACA TN 2565

A THEORETICAL ANALYSIS OF THE EFFECT OF SEVERAL AUXILIARY DAMPING DEVICES ON THE LATERAL STABILITY AND CONTROLLABILITY OF A HIGH-SPEED AIRCRAFT. Ordway B. Gates, Jr. December 1951. 39p. diagrs., 6 tabs. (NACA TN 2565)

An investigation has been made to determine the effect of several auxiliary damping devices on the lateral stability and controllability of a present-day high-speed airplane. The results are presented in the form of aircraft motions subsequent to applied yawing or rolling moments, comparisons of the time to damp to half amplitude and the period of the lateral modes of motion, rudder motion required for zero sideslip subsequent to an aileron deflection, and combinations of rudder and aileron deflection necessary to perform steady turning maneuvers for each of the investigated damping devices.

NACA TN 2566

A STUDY OF ELASTIC AND PLASTIC STRESS CONCENTRATION FACTORS DUE TO NOTCHES AND FILLETS IN FLAT PLATES. Herbert F. Hardrath and Lachlan Ohman. December 1951. 23p. diagrs. (NACA TN 2566)

Six large 24S-T3 aluminum-alloy-sheet specimens containing various notches or fillets were tested in tension to determine their stress concentration factors in the elastic and plastic ranges. The elastic stress concentration factors were found to be slightly higher than those predicted by other methods. A generalization of a relation presented by Stowell gave good agreement with the plastic stress concentration factors as they decreased with increasing plastic strain.

NACA TN 2569

A SUMMARY OF METEOROLOGICAL CONDITIONS ASSOCIATED WITH AIRCRAFT ICING AND A PROPOSED METHOD OF SELECTING DESIGN CRITERIONS FOR ICE-PROTECTION EQUIPMENT. Paul T. Hacker and Robert G. Dorsch. November 1951. 35p. diagrs. (NACA TN 2569)

Data on the meteorological parameters pertinent to the aircraft icing problem are so summarized as to give the frequency of occurrence of observed icing situations according to two of the parameters. The summarized data indicate that statistical relations exist between some of the parameters. A method, based upon the collection efficiency of an airfoil and the frequency of occurrence of icing situations with various liquid-water contents and mean-effective droplet sizes, is proposed for the selection of design criterions for ice-protection equipment. The method provides a convenient means of calculating the percentage of icing encounters in which the water collection rate exceeds the design rate.

NACA TN 2578

A COMPARISON OF PREDICTED AND EXPERIMENTALLY DETERMINED LONGITUDINAL DYNAMIC RESPONSES OF A STABILIZED AIRPLANE. Louis H. Smaus, Marvin R. Gore and Merle G. Waugh. December 1951. 53p. diagrs., photos. (NACA TN 2578)

The dynamic stability in pitch of an aircraft with autopilot was predicted by combining ground measured autopilot transfer functions to obtain open-loop and closed-loop frequency responses and transient responses for the combination. These predicted responses for three airspeeds and for various amounts of displacement and rate-of-displacement feedback are compared with corresponding frequency and transient responses of the stabilized airplane as measured in flight.

NACA TN 2579

APPROXIMATE METHODS FOR CALCULATING THE FLOW ABOUT NONLIFTING BODIES OF REVOLUTION AT HIGH SUPERSONIC AIRSPEEDS. A. J. Eggers, Jr. and Raymond C. Savin. December 1951. 40p. diagrs. (NACA TN 2579)

Explicit expressions are developed which yield the Mach number and pressure distributions on the surfaces of pointed nonlifting bodies of revolution operating at high supersonic airspeeds and at values of the hypersonic similarity parameter (ratio of free-stream Mach number to slenderness ratio) greater than 1. Very simple explicit expressions are obtained for these distributions in the special case of slender bodies. In the case of cones, the analytic solutions accurately define the entire flow field over a wide range of free-stream Mach numbers and apex angles.

NACA TN 2580

AN ANALYSIS OF AN X-RAY ABSORPTION METHOD FOR MEASUREMENT OF HIGH GAS TEMPERATURES. Ruth N. Weltmann and Perry W. Kuhns. December 1951. 35p. diagrs., photos., 2 tabs. (NACA TN 2580)

An analysis is presented of an X-ray absorption method for determining high gas temperatures. The

indicated temperature represents the mean density of the gas. Correction factors for dissociation and air-gas mixture are calculated as a function of temperature for stoichiometric mixtures of hydrocarbons and air. Design suggestions for a practical instrument are given on the basis of a theoretical analysis, which is corroborated by a few experimental data.

NACA RM E51I05

COMPARISON OF HIGH-SPEED OPERATING CHARACTERISTICS OF SIZE 215 CYLINDRICAL-ROLLER BEARINGS AS DETERMINED IN TURBO-JET ENGINE AND IN LABORATORY TEST RIG. E. Fred Macks and Zolton N. Nemeth. November 1951. 33p. diagrs., photos., tab. (NACA RM E51I05)

Inner- and outer-race cooling-correlation curves were obtained for the turbojet-engine turbine-roller bearing with the same inner- and outer-race cooling-correlation parameters and exponents as those determined for the test-rig bearing. The inner- and outer-race turbine roller-bearing temperatures may be predicted from a single curve regardless of variations in speed, load, oil flow, oil inlet temperatures, oil inlet viscosity, oil-jet diameter, or any combination of these parameters.

NACA RM E51I10

ELEVATED TEMPERATURE PROPERTIES OF TITANIUM CARBIDE BASE CERAMALS CONTAINING NICKEL OR IRON: A. L. Cooper and L. E. Colteryahn. December 1951. 47p. photos., diagrs., 5 tabs. (NACA RM E51I10)

Elevated-temperature properties of titanium carbide base ceramals containing nickel or iron were determined in oxidation, modulus of rupture, tensile strength, and thermal-shock resistance. Metallographic structure was studied. These materials followed the general growth law and exhibited two stages in oxidation. The following tensile strengths were found at 2000° F; 13.3 weight percent nickel, 16,150 pounds per square inch; 11.8 weight percent iron, 12,500 pounds per square inch; unalloyed titanium carbide, 16,450 pounds per square inch. Nickel or iron additions to titanium carbide improved the thermal-shock resistance, nickel more. The path of fracture in tensile and thermal-shock specimens was found to progress approximately 50 percent intergranularly and 50 percent transgranularly.

NACA RM E51I18

FORCED-CONVECTION HEAT TRANSFER TO WATER AT HIGH PRESSURES AND TEMPERATURES IN THE NONBOILING REGION. S. J. Kaufman and R. W. Henderson. November 1951. 16p. diagrs., photos. (NACA RM E51I18)

Forced-convection heat-transfer data have been obtained for water flowing in an electrically heated tube of circular cross section at water pressures of 200 and 2000 pounds per square inch, and temperatures in the nonboiling region, for water velocities ranging between 5 and 35 feet per second. The results indicate that conventional correlations can be used to predict heat-transfer coefficients for water at pressures up to 2000 pounds per square inch and temperatures in the nonboiling region.

NACA RM E51J05

FUNDAMENTAL FLAME VELOCITIES OF PURE HYDROCARBONS. III - EXTENSION OF TUBE METHOD TO HIGH FLAME VELOCITIES - ACETYLENE-AIR MIXTURES. Oscar Levine and Melvin Gerstein. December 1951. 21p. diagrs. (NACA RM E51J05)

The tube method of measuring flame velocities has been extended to fundamental flame velocities of 141 centimeters per second. This extension was accomplished by reducing the flame-tube diameter from 25 to 12.5 millimeters. The reduction in flame-tube diameter decreased the Reynolds number of the unburned gas ahead of the flame from a turbulent to a laminar region. The gas-velocity correction in the 12.5-millimeter flame tube fits the empirical linear relation between gas velocity and spatial flame velocity previously obtained in the 25-millimeter flame tube. The ratio of the flame tube cross sectional area to the flame surface area was found to be the same constant in the 25- and the 12.5-millimeter flame tubes. A simplified equation for calculating the flame surface area from flame photographs is presented.

NACA RM E51J09

VARIATION OF THE PRESSURE LIMITS OF FLAME PROPAGATION WITH TUBE DIAMETER FOR PROPANE-AIR MIXTURES. Frank E. Belles and Dorothy M. Simon. December 1951. 17p. diagrs., tab. (NACA RM E51J09)

An investigation was made of the variation of the pressure limits of flame propagation with tube diameter for quiescent propane-air mixtures. Pressure limits were measured in glass tubes of six different inside diameters, with a precise apparatus. Critical diameters for flame propagation were calculated and the effect of pressure was determined. The critical diameters depended on the pressure to the -0.97 power for stoichiometric mixtures. The pressure dependence decreased with decreasing propane concentration. Critical diameters were related to quenching distance, flame speeds, and minimum ignition energy.

NACA TM 1316

RESISTANCE OF A PLATE IN PARALLEL FLOW AT LOW REYNOLDS NUMBERS. (Odpor podélne obtékané desky pri malých Reynoldsových číslech). Zbynek Janour. November 1951. 40p. diagrs., tab. (NACA TM 1316. Trans. from Letecký Vyzkumný Ústav, Praha, Rept. 2, 1947).

The present paper gives the results of measurements of the resistance of a plate placed parallel to the flow in the range of Reynolds numbers from 10 to 2300; in this range the resistance deviates from the formula of Blasius. The lower limit of validity of the Blasius formula is determined and also the increase

in resistance at the edges parallel to the flow in the case of a plate of finite width.

NACA TM 1319

TORSION AND BENDING OF PRISMATIC RODS OF HOLLOW RECTANGULAR SECTION. (Kruchenie i Izgib Prismaticheskikh Sterzhnei s Polym Pryamougol'nym Secheniem). B. L. Abramyan. November 1951. 24p. diagrs., 2 tabs. (NACA TM 1319. Trans. from Prikladnaya Mathematika i Mekhanika, v.14, no.3, 1950, p.265-276).

The torsion and bending of hollow rectangular beams was investigated without the requirement that the wall thickness be small compared with the transverse dimensions. The limits of applicability of the usual Bredt formula are indicated for the case of a square hollow tube in torsion. Formulas are given for bending stresses at different parts of the cross section of a hollow rectangular beam.

NACA TM 1321

RELATIONS BETWEEN THE MODULUS OF ELASTICITY OF BINARY ALLOYS AND THEIR STRUCTURE. (Beziehungen zwischen dem Elastizitatsmodul von Zweistofflegierungen und ihrem Aufbau). Werner Köster and Walter Rauscher. November 1951. 49p. diagrs. (NACA TM 1321. Trans. from Zeitschrift für Metallkunde, v.39, 1948, p.111-120. Dissertation Technische Hochschule Stuttgart, 1942).

A comprehensive survey of the elastic modulus of binary alloys as a function of the concentration is presented. Alloys that form continuous solid solutions, limited solid solutions, eutectic alloys, and alloys with intermetallic phases are investigated. Systems having the most important structures have been examined to obtain criteria for the relation between lattice structure, type of binding, and elastic behavior.

NACA TM 1326

CONCERNING THE FLOW ABOUT RING-SHAPED COWLINGS. PART II - ANNULAR BODIES OF INFINITE LENGTH WITH CIRCULATION FOR SMOOTH ENTRANCE. (Über die Strömung an ringförmigen Verkleidungen. II. Mitteilung: Ringkörper unendlicher Tiefe mit Zirkulation bei stossfreiem Eintritt). Dietrich Küchemann and Johanna Weber. November 1951. 41p. diagrs. (NACA TM 1326. Trans. from Zentrale für wissenschaftliches Berichtswesen über Luftfahrtforschung, Berlin. FB 1236/2, November 11, 1940).

The investigations carried out in a previous report (NACA TM 1325) concerning the flow about ring-shaped cowlings were extended by taking a circulation about the cowling into consideration. The present second report treats bodies of infinite length with approximately smooth entrance. The circulation was caused by distributing vortex rings of constant density over a stream surface extending to infinity. Furthermore, the influence of a hub body on such cowlings was dealt with. The examples treated are meant to give to the designer a basis for his design.

BRITISH REPORTS

N-11151*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) VARSITY T. MK.1 VX.835 (2 x HERCULES 265). MEASURED LANDINGS. August 14, 1951. 6p. curves, tab. (AAEE Rept. A.A.E.E./873, pt.15)

Using a glide approach with full flap at 85 knots I.A.S., the landing distances were 365 yards from 50 feet to touchdown, and a further 600 yards from touchdown to stop, the values being corrected to an aircraft weight of 36,000 pounds to I.C.A.N. sea-level conditions, on a level tarmac runway. It was considered, however, that the use of full braking during these landing runs was to some extent prejudiced by the harshness of the brake control combined with the need to minimize the occurrence of tire slip (or wheel locking).

Royal Aircraft Establishment (Gt. Brit.) THE THEORETICAL WAVE DRAG OF SOME BODIES OF REVOLUTION. L. E. Fraenkel. May 1951. 41p. diagrs., tab. (RAE Aero 2420)

The results of linearized theory for the wave drag of bodies of revolution are applied to bodies whose profiles (meridian sections) are either straight or parabolic arcs. Forebody and afterbody drag are examined; a reversibility theorem is established; and the interference effect of the forebody on the afterbody is investigated. Two different types of approximation are considered and their results are compared.

N-11238*

Royal Aircraft Establishment (Gt. Brit.) GUST ALLEVIATION FACTOR. J. Zbrozek. May 1951. 45p. diagrs. (RAE Aero 2421)

Presents theoretical calculations of gust alleviation factor made for rigid aircraft and with one degree of freedom only (that is, vertical motion). It is shown that for average gust lengths and for orthodox (tailed) aircraft the influence of the second degree of freedom (that is, pitching) on the value of the gust alleviation factor is negligibly small, providing the pitching moment of inertia is not unduly small. The influence of aspect ratio, the importance of the mass parameter, and the gust shape on the values of the gust alleviation factor are shown. The large influence of the gust shape on the value of the alleviation factor makes the gust analysis by simple measurements of maximum aircraft acceleration inadequate, and the full records of the time history of the aircraft are necessary. An alternative, more direct method of gust measurements is suggested.

NO. 14 DECEMBER 31, 1951

CURRENT NACA REPORTS

NACA TN 2445

WIND-TUNNEL TESTS AT LOW SPEED OF SWEPT AND YAWED WINGS HAVING VARIOUS PLAN FORMS. Paul E. Purser and M. Leroy Spearman. December 1951. 82p. diagrs., photos., 2 tabs. (NACA TN 2445. Formerly RM L7D23)

Results are presented of wind-tunnel tests made at low speed of various small-scale models of sweptback, sweptforward, and yawed wings. The tests covered changes in aspect ratio, taper ratio, and tip shape. Some data were obtained with high-lift devices on sweptback wings and with ailerons on sweptforward wings. The data have been briefly analyzed and some comparisons have been made with the available theory.

NACA TN 2553

PITCHING-MOMENT DERIVATIVES C_{m_q} AND $C_{m_{\dot{\alpha}}}$ AT SUPERSONIC SPEEDS FOR A SLENDER-DELTA-WING AND SLENDER-BODY COMBINATION AND APPROXIMATE SOLUTIONS FOR BROAD-DELTA-WING AND SLENDER-BODY COMBINATIONS. Arthur Henderson, Jr. December 1951. 29p. diagrs. (NACA TN 2553)

The pitching-moment derivatives C_{m_q} and $C_{m_{\dot{\alpha}}}$ for supersonic speeds are developed for a slender-delta-wing and slender-body combination having no afterbody. By drawing an analogy between the aerodynamics of the wing-body section of the configuration and the aerodynamics of a delta wing alone, the results for the slender-delta-wing and slender-body combination are modified to the extent that approximate solutions for C_{m_q} and $C_{m_{\dot{\alpha}}}$ for broad-delta-wing and slender-body combinations can be obtained.

NACA TN 2563

EXPERIMENTAL INVESTIGATION OF ROLLING PERFORMANCE OF STRAIGHT AND SWEPTBACK FLEXIBLE WINGS WITH VARIOUS AILERONS. Henry A. Cole, Jr. and Victor M. Ganzer, University of Washington. December 1951. 45p. diagrs., photos., 2 tabs. (NACA TN 2563)

An experimental investigation was conducted to determine the performance in roll of two flexible wings, one swept back 45° and the other unswept. Rolling moments due to aileron deflection, damping derivatives in roll, and free-rolling angular velocities due to aileron deflection were obtained at various speeds including, when possible, the aileron reversal speed.

NACA TN 2568

EFFECT OF SLIP ON FLOW NEAR A STAGNATION POINT AND IN A BOUNDARY LAYER. T. C. Lin and S. A. Schaaf, University of California. December 1951. 28p. diagrs. (NACA TN 2568)

Theoretical analyses are presented of the effect of slip on the flow of a rarefied gas near a stagnation point and in a boundary layer on a flat plate. The results indicate that the stagnation pressure is increased because of the effect of slip but that there is a negligible effect on the flat-plate skin-friction coefficient in the range of application of the analysis.

NACA TN 2572

CERAMIC COATINGS FOR PREVENTION OF CARBON ABSORPTION IN FOUR HEAT-RESISTANT ALLOYS. Joseph W. Pitts and Dwight G. Moore, National Bureau of Standards. December 1951. 14p. diagr., photos., 3 tabs. (NACA TN 2572)

Three ceramic coatings were applied to four heat-resistant alloys (three types of 18-8 stainless steel and Inconel) and then tested for their effectiveness in preventing carbon absorption after box carburizing for 4 hours at 1350° to 1650° F. Carbon absorption that occurred on uncoated specimens at these conditions was inhibited by the application of a ceramic coating. The coating apparently seals the surface of the alloy from carburizing gases and thus prevents carbon pickup and resulting precipitation of carbides at or near the grain boundaries.

NACA TN 2576

A STUDY OF SLIP FORMATION IN POLYCRYSTALLINE ALUMINUM. Aldie E. Johnson, Jr. and S. B. Batdorf. December 1951. 18p. photos., diagr., tab. (NACA TN 2576)

Experimental results are presented which shed light on the assumptions that have been made in several attempts to bridge the gap between the physical and mathematical theories of plasticity. The experimental results are compatible with, but do not necessarily verify, the conception that plastic deformation in strain-hardening materials is primarily due to slip. Slip was observed to occur first in a few iso-

lated grains and to spread gradually to adjacent grains as the stress level increased. The occurrence and spread of the slip lines suggested independent behavior of randomly oriented grains at low stress levels with interaction among grains increasing as the stress level increased.

NACA TN 2577

ON THE ANGULAR DISTRIBUTION OF SLIP LINES IN POLYCRYSTALLINE ALUMINUM ALLOY. John M. Hedgepeth, S. B. Batdorf and J. Lyell Sanders, Jr. December 1951. 18p. photos., diagrs., tab. (NACA TN 2577)

A rather wide distribution in the angular orientation of slip lines is generally observed in various grains of a metal subjected to plastic deformation. The relative frequency of occurrence of any given slip line angle for the case of simple tension has been derived on the basis of a model of a plastically deforming polycrystal that was recently used as the basis of a theory of polyaxial stress-strain relations (the so-called slip theory of plasticity). The results are compared with experiment and conclusions are drawn as to the limitations of the model.

NACA TN 2583

A SEMIEMPIRICAL PROCEDURE FOR COMPUTING THE WATER-PRESSURE DISTRIBUTION ON FLAT AND V-BOTTOM PRISMATIC SURFACES DURING IMPACT OR PLANING. Robert F. Smiley. December 1951. 28p. diagrs. (NACA TN 2583)

A semiempirical procedure is presented for computing the water-pressure distribution on flat and V-bottom prismatic surfaces during planing or landings. For the rectangular flat plate, calculated and experimental pressure distributions are in good agreement for trims below 30° and for wetted-length-beam ratios at least up to 3.3. For the case of a V-bottom prismatic surface with appreciable chine immersion, the pressures on chine-immersed sections of a model having an angle of dead rise of 30° are similar to those on the corresponding flat plate so that a simple modification of the flat-plate procedure can be used to predict approximately the pressures on V-bottom surfaces.

NACA TN 2584

AN ANALYSIS OF THE FLOW IN THE ROTATING PASSAGE OF LARGE RADIAL-INLET CENTRIFUGAL COMPRESSOR AT A TIP SPEED OF 700 FEET PER SECOND. Vasily D. Prian and Donald J. Michel. December 1951. 46p. diagrs., photo., tab. (NACA TN 2584)

An analysis of the flow in the rotating passage of a 48-inch diameter radial-inlet centrifugal impeller at a tip speed of 700 feet per second indicated that a region of low efficiency generally existed along the trailing face as a result of a combination of shifting of low energy air toward the trailing face and losses arising from the decelerations along the trailing face. Because of the comparatively large viscous losses along the trailing face, and with the unloading of the blades, the velocity at the driving face tip was higher than the trailing face tip. This velocity difference would be expected to result in mixing losses upon diffusion of the air. The theoretically predicted eddy on the driving face was not found experimentally. Modification of the theoretical entrance angle of flow for the first 15 percent of the passage gave fair agreement between the theoretical and experimental static pressures at off-design conditions except for the maximum flow conditions.

NACA RM E51J12

SPARK IGNITION OF FLOWING GASES. II - EFFECT OF ELECTRODE PARAMETERS ON ENERGY REQUIRED TO IGNITE A PROPANE-AIR MIXTURE. Clyde C. Swett, Jr. December 1951. 26p. diagrs., photos. (NACA RM E51J12)

The effect of electrode spacing, configuration, and material on the energy required for ignition of a propane-air mixture at a pressure of 3 inches mercury absolute was determined. The energy required decreased and then increased as the spacing was increased; a minimum occurred at a spacing of 0.65 inch. Small-diameter electrodes required less energy than large-diameter electrodes if the spacing was less than optimum; at the spacing of 0.65 inch no differences were observed. Glow discharges required more energy for ignition than the arc-glow discharges; with glow discharges the effect of electrode material was negligible. A determination of the energy distribution along the discharge showed one-third to one-half of the energy to be concentrated in a small region near the cathode and the remainder uniformly distributed across the spark gap. Long-duration (600-microsec) sparks required much less energy than the short-duration (1-microsec) sparks.

Royal Aircraft Establishment (Gt. Brit.) COMPARATIVE CORROSION TESTS ON MAGNESIUM ALLOY PARTS AND ALUMINUM ALLOY PARTS OF ELECTRICAL EQUIPMENT IN SALT FOG, AND CORROSION TESTS ON MAGNESIUM ALLOY CASTINGS IN A HUMIDITY CHAMBER. R. F. Sims and E. C. Railton. January 1951. 11p. photos. (RAE Tech. Note EL. 20)

Comparative tests under severe salt-fog conditions show that corrosion of properly treated magnesium alloys is no worse than that of aluminum alloys. Since aluminum has been widely used for parts of electrical equipment in sea-going aircraft, it should be possible to use magnesium alloy parts for similar purposes and so save weight. Points at which other metals contact the magnesium will need careful protection, however, if corrosion is to be avoided.

GRAPHITE LUBRICATION AND THE WEAR OF CARBON BRUSHES AT HIGH ALTITUDES. R. F. Sims. April 1951. 19p. diagrs. (RAE Tech. Note EL. 24)

The lubricity of graphite in normal atmospheric conditions is shown to be due to absorbed films of water. In dry atmospheres the water films are not maintained and where graphite brushes are running on commutators, seizure occurs, with resultant high rates of wear. Brushes may be treated with substances e. g. some metallic halides, which partly replace the water film, but their performance in extremely dry conditions depends critically on previous running of the bursh with the commutator in moist conditions.

RADIO FREQUENCY AND OTHER HEATING PROCESSES. A CALORIMETRIC METHOD OF ASSESSMENT OF THE R. F. CONDUCTIVITY OF GLUES. P. M. C. Lacey and G. E. Soane. (Progress Rept. 9.) August 1951. 8p. diagrs. (Forest Products Research Lab.)

The radio frequency conductivity of a number of synthetic resin glues has been determined over a wide range of temperature, to an accuracy of about ±15 percent by a calorimetric method, and compared with the voltages needed to set the same glues in wood joints. It is concluded that conductivity is not a reliable guide to set voltage.

CALCULATION OF THE DAMPING FOR ROLLING OSCILLATIONS OF A SWEPT WING. Doris E. Lehrian. 1951. 10p. diagrs., tab. (ARC CP 51; ARC 13, 448)

The damping derivative for rolling oscillations of a swept and an unswept wing, each of aspect ratio 6 is calculated for a range of frequency parameter values. Good agreement with experiment is obtained for the larger values of the frequency parameter. For the lower values the results diverge slightly; this difference may be partly due to the approximations made in the calculation, and partly due to the greater importance of tunnel wall interference effects as the frequency parameter tends to zero.

OBSERVATIONS OF THE INTERACTION BETWEEN THE SHOCK WAVES AND BOUNDARY LAYERS AT THE TRAILING EDGES OF AEROFOILS IN SUPERSONIC FLOW. D. W. Holder and R. J. North. December 28, 1950. 12p. photos., diagrs. (ARC CP 53; ARC 13,621)

Photographs have been taken of the flow at the trailing edges of three unyawed, two-dimensional airfoils placed in an airstream moving with a Mach number of 1.6 and giving a Reynolds number (based on chord) of 0.8×10^6. It is found that the conditions close to the trailing edge depend on the strength of the trailing-edge shock, particularly if the boundary layer is laminar ahead of the shock.

MEAN-SPEED MEASUREMENTS IN TWO-DIMENSIONAL, INCOMPRESSIBLE, FULLY-DEVELOPED TURBULENT CHANNEL FLOW. George T. Skinner. 1950. 44p. diagrs. (Calif. Inst. of Tech. Guggenheim Aeronautical Lab.)

Mean velocity profiles were measured in a 5-inch by 60-inch wind channel by the use of a hot-wire anemometer. Repeatability of results was established and accuracy of the instrumentation was estimated. A little scatter may have been caused by humidity variations and slight flow unsteadiness. Irregularities of a hot-wire in close proximity to a solid boundary at low speeds were observed. It was found that Kármán's logarithmic law holds reasonably well. The values of the constants for the law for the best over-all agreement were determined and compared with those obtained by others.

INVESTIGATION OF THE NACA 4-(5)(08)-03 AND NACA 4-(10)(08)-03 TWO-BLADE PROPELLERS AT FORWARD MACH NUMBERS TO 0.725 TO DETERMINE THE EFFECTS OF CAMBER AND COMPRESSIBILITY ON PERFORMANCE. James B. Delano. 1951. 31p. photos., diagrs. (NACA Rept. 1012. Formerly ACR L5F15)

The effects of blade section and camber and compressibility on propeller characteristics are presented for forward Mach numbers from 0.165 to 0.725 for blade angles from 20° to 60°. The camber-range investigated corresponds to section design lift coefficients of 0.3, 0.5, and 1.0.

NACA TN 2508

LANDING CHARACTERISTICS IN WAVES OF THREE DYNAMIC MODELS OF FLYING BOATS. James M. Benson, Robert F. Havens and David R. Woodward. January 1952. 41p. diagrs., photo., 2 tabs. (NACA TN 2508. Formerly RM L6L13)

Powered models of three different flying boats were landed in oncoming waves of various heights and lengths. The effects of varying the trim at landing, the deceleration after landing, and the size of the waves were determined. Data are presented on the motions and accelerations obtained during landings in rough water.

NACA TN 2538

MECHANICAL AND CORROSION TESTS OF SPOT-WELDED ALUMINUM ALLOYS. Fred M. Reinhart, National Bureau of Standards, and W. F. Hess, R. A. Wyant, F. J. Winsor and R. R. Nash, Rensselaer Polytechnic Institute. December 1951. 74p. diagrs., photos., 19 tabs. (NACA TN 2538)

Corrosion behavior of spot-welded aluminum-alloy (alclad 24S-T3, 24S-T3, alclad XB75S-T6, XB75S-T6, and R-301-T6) panels of varying weld quality was determined. Tidewater and weather exposure tests were made and the results were evaluated largely in terms of distribution of corrosion products and effects on weld strength. Metallographic examinations of several of the alloys were also made to determine the extent and type of corrosion attack associated with various welding and exposure conditions.

NACA TN 2573

DEVELOPMENT OF AUXILIARY CYCLOTRON EQUIPMENT FOR USING TRITIUM AS BOMBARDING PARTICLES IN A CYCLOTRON. D. N. Kundu, F. G. Boyle and M. L. Pool, Ohio State University. December 1951. 19p. diagrs. (NACA TN 2573)

A circulating system for radioactive tritium was constructed, assembled, and tested. The results showed that the pumping speed of the system was too low for use. With a sufficiently increased pumping speed, it is believed that the circulating system would provide satisfactory operation.

NACA TN 2574

THEORETICAL ANALYSIS OF SOME SIMPLE TYPES OF ACCELERATION RESTRICTORS. William H. Phillips. December 1951. 35p. diagrs., 2 tabs. (NACA TN 2574)

Acceleration restrictors which work on the principle of stopping the upward motion of the elevator when the signal from an acceleration-sensing device reaches a certain value have been analyzed for representative fighter and transport airplanes over a range of altitude and center-of-gravity positions.

NACA TN 2575

A FLIGHT INVESTIGATION OF THE EFFECT OF CENTER-OF-GRAVITY LOCATION ON GUST LOADS. Jack Funk and Earle T. Binckley. December 1951. 18p. diagrs., 3 tabs. (NACA TN 2575)

Two jet-propelled airplanes were flown in rough air to investigate the effects of center-of-gravity location on gust loads. Data were obtained at centers of gravity of 20.9 and 27.5 percent mean aerodynamic chord for incremental load factor up to 1 g. The results indicate that a 6.6-percent forward movement of center of gravity decreases the gust loads by approximately 10 percent. The most frequently occurring distance from 1 g to peak acceleration was 17.5 chords. Calculations of the change in normal acceleration for a center-of-gravity movement from 20.9 to 27.5 percent mean aerodynamic chord for a single triangular gust having a gradient distance of 17.5 chords were in good agreement with the test results.

NACA TN 2581

DEFLECTIONS OF A SIMPLY SUPPORTED RECTANGULAR SANDWICH PLATE SUBJECTED TO TRANSVERSE LOADS. Kuo Tai Yen, Sadettin Gunturkun and Frederick V. Pohle, Polytechnic

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER, TITLE AND AUTHOR.

Institute of Brooklyn. December 1951. 39p. curves, diagrs., 3 tabs. (NACA TN 2581)

The differential equations of the bending of sandwich plates were integrated to obtain the deflections when the four edges of the plate are simply supported and the loading consists of either a uniformly distributed transverse load or a concentrated load applied at the center of the panel. The deflection patterns are shown in diagrams and the maximum deflection of the plate is presented in a number of graphs.

NACA TN 2582

GENERAL CONSIDERATION OF PROBLEMS IN COMPRESSIBLE FLOW USING THE HODOGRAPH METHOD. Chieh-Chien Chang, Johns Hopkins University. January 1952. 113p. diagrs. (NACA TN 2582)

This is an investigation of the hodograph method as it is applied in general to the problem of compressible flow. The hodograph equations are given in various canonical forms convenient for obtaining solutions in the different flow regimes. However, since the coefficients of the canonical differential equations are implicit functions and therefore exact solutions are difficult to find, different approximations are chosen so that simpler differential equations can be obtained. The detailed development is concentrated on Chaplygin's second equation. The first-order approximation is well known as the Tricomi equation; the second- and third-order approximations follow the exact gas law closely in the neighborhood of sonic velocity. The flow through an aperture is reexamined by comparing the present approximate relation with the exact Chaplygin solutions.

NACA TN 2586

FUNDAMENTAL EFFECTS OF COLD-WORK ON SOME COBALT-CHROMIUM-NICKEL-IRON BASE CREEP-RESISTANT ALLOYS. D. N. Frey, J. W. Freeman and A. E. White, University of Michigan. January 1952. 12p. diagrs. (NACA TN 2586)

The influence of cold-working on creep properties of an alloy containing 20-percent cobalt, 20-percent chromium, 20-percent nickel, and the balance iron and on the same alloy modified by small additions of tungsten alone or tungsten, molybdenum, and columbium in combination was studied. Effects of cold-working on creep resistance were the same for all alloys studied for temperatures up to 1600° F and reductions between 15 and 40 percent. Conclusions were reached by studying creep properties and also internal stress relaxation at test temperatures which previous work had shown to be the controlling factor in response of such alloys to cold-working.

NACA TN 2587

INFLUENCE OF WING AND FUSELAGE ON THE VERTICAL-TAIL CONTRIBUTION TO THE LOW-SPEED ROLLING DERIVATIVES OF MIDWING AIRPLANE MODELS WITH 45° SWEPTBACK SURFACES. Walter D. Wolhart. December 1951. 55p. diagrs., photo., 3 tabs. (NACA TN 2587)

Results are presented of an investigation to determine the influence of the wing and fuselage on the vertical-tail contribution to the rolling derivatives of midwing airplane models with 45° sweptback surfaces. Comparisons are also made between measured and calculated vertical-tail contributions to the rolling derivatives which include corrections for the effect of fuselage and wing sidewash due to roll.

NACA TN 2589

AN ANALYTICAL INVESTIGATION USING AERODYNAMIC LIMITATIONS OF SEVERAL DESIGNS OF HIGH STAGE PRESSURE RATIO MULTISTAGE COMPRESSORS. Charles H. Voit and Arthur R. Thomson. December 1951. 56p. diagrs., 2 tabs. (NACA TN 2589)

An analysis of the effect of the principal design variables on the stagewise design-point characteristics of axial-flow compressors having high average stage pressure ratios was made. The investigation considered certain design limits and the manner in which they are affected by the principal design variables. Optimum stagewise variations of axial velocity and relative inlet-air angle were determined. An estimate was made of the obtainable over-all total pressure ratio by the use of several stagewise distributions of these variables.

NACA TN 2595

DESIGN OF TWO-DIMENSIONAL CHANNELS WITH PRESCRIBED VELOCITY DISTRIBUTIONS ALONG THE CHANNEL WALLS. II - SOLUTION BY GREEN'S FUNCTION. John D. Stanitz. January 1952. 35p. diagrs., 2 tabs. (NACA TN 2595)

Methods of solution by Green's function are developed for the design of two-dimensional unbranched channels with prescribed velocities as a function of arc length along the channel walls. The methods apply to incompressible and linearized compressible, nonviscous irrotational flow. One numerical example is presented for an accelerating elbow with linearized compressible flow. The elbow shape obtained from the solution by Green's function is the same as that obtained from a solution by relaxation methods for the same prescribed conditions. The time required for the calculations is considerably less for solutions by Green's function.

NACA TM 1327

CONCERNING THE FLOW ABOUT RING-SHAPED COWLINGS. PART VI - FURTHER MEASUREMENTS ON INLET DEVICES. (Uber die Strömung an ringförmigen Verkleidungen. VI. Mitteilung: Weitere Messungen an Einlaufgeräten). Dietrich Kuchemann and Johanna Weber. December 1951. 21p. diagrs. (NACA TM 1327. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1236/6, March 30, 1942).

The present report presents as a supplement to the fourth report (available as ATI 50545, Air Materiel Command) in the series of investigations concerning the flow about ring-shaped cowlings further wind-

tunnel measurements on inlet devices which are to show the influence of the radius of the nose of the cowling on the flow conditions. Moreover, a simple rule for the design of such arrangements, containing a hub in the interior, is suggested.

APPROXIMATE SOLUTION TO VISCOUS FLOW AT LOW SPEEDS. I. FLOW PAST CIRCULAR CYLINDER. (Nenseiryutai No Osoi Nagare Ni Taisuru Hitotsu No Kinji Kaiho). Mitsutoshi Kawaguchi. 12p. diagrs., 2 tabs. (Trans. from Tokyo (Imperial) Univ., Institute of Science and Technology, Reports, v. 2, no. 3-4, Mar. -Apr., 1948, p. 33-37).

The stream function for $R = 10$ to $R = 20$ is analytically studied by developing it into a finite number of terms in order to approximately satisfy the Navier-Stokes equation. The results thus obtained may be considered to agree fairly well with experimental results. In the second approximation there was added the condition that the derivative of the equation of motion is satisfied at $r = 1$ but the approximation became impaired for $R > 20$.

NACA Rept. 1010

A RECURRENCE MATRIX SOLUTION FOR THE DYNAMIC RESPONSE OF AIRCRAFT IN GUSTS. John C. Houbolt. 1951. ii, 31p. diagrs., 7 tabs. (NACA Rept. 1010. Formerly NACA TN 2060)

Through the use of different equations and matrix notation a systematic procedure is developed for the calculation of the structural response of an aircraft flying through a gust. The method takes into account wing bending and twisting flexibilities, fuselage flexibility, vertical and pitching motion of the airplane, and some tail forces. Strip theory is used, but approximate three-dimensional and compressibility corrections can be made without difficulty. Either sharp-edge or arbitrary gusts may be treated.

NACA Rept. 1021

ANALYSIS OF PLANE-PLASTIC-STRESS PROBLEMS WITH AXIAL SYMMETRY IN STRAIN-HARDENING RANGE. M. H. Lee Wu. 1951. ii, 23p. diagrs. (NACA Rept. 1021. Formerly NACA TN 2217)

A method, based on the deformation theory and employing the finite-strain concept, was developed to solve plane-stress problems in the strain-hardening range of circular membrane, rotating disk, and infinite plate with circular hole. Distributions of octahedral shear strain, as well as principal stresses and strains, were obtained. Results show that: (1) Ratios of principal stresses remain essentially constant during loading; (2) distributions of strain in the plastic case are less uniform than in the elastic case, although distributions of stress are more uniform; (3) the deformation that can be accepted by the member depends mainly on the maximum octahedral shear strain of the material; and (4) the added load that the member can sustain between the onset of yielding and failure depends on octahedral shear stress-strain relation of the material.

NACA Rept. 1022

TEMPERATURE DISTRIBUTION IN INTERNALLY HEATED WALLS OF HEAT EXCHANGERS COMPOSED OF NONCIRCULAR FLOW PASSAGES. E. R. G. Eckert and George M. Low. 1951. ii, 14p. diagrs. (NACA Rept. 1022. Formerly TN 2257)

A method for the determination of circumferential temperature distributions and heat-transfer characteristics of heat exchangers composed of polygonal flow passages is developed. The passage walls are heated uniformly by internal heat sources and the coolant flow within the passages is turbulent. Applications of the method to heat exchangers with rectangular and triangular passages are presented.

NACA Rept. 1023

DIFFUSION OF CHROMIUM IN ALPHA COBALT-CHROMIUM SOLID SOLUTIONS. John W. Weeton. 1951. ii, 15p. diagrs., photos., tab. (NACA Rept. 1023. Formerly TN 2218)

Diffusion of chromium in α coblat-chromium solid solutions was investigated in the range of 0 to 40 atomic percent at temperatures of 1360°, 1300°, 1150°, and 1000° C. The activation heat of diffusion was determined to be 63,600 calories per mole and the equation relating diffusion D and temperature T is $D = 0.443\, e^{-\frac{63,600}{RT}}$ where R is the gas constant. When compared with most alloy systems for which diffusion data have been previously obtained, the diffusion rates of chromium in α colbalt-chromium solid solutions were found to be low.

NACA TN 2435

DIRECT-READING DESIGN CHARTS FOR 75S-T6 ALUMINUM-ALLOY FLAT COMPRESSION PANELS HAVING LONGITUDINAL EXTRUDED Z-SECTION STIFFENERS. William A. Hickman and Norris F. Dow. February 1952. 60p. diagrs., photos., 8 tabs. (NACA TN 2435)

Direct-reading design charts are presented for 75S-T6 aluminum-alloy flat compression panels having longitudinal extruded Z-section stiffeners. These charts, which cover a wide range of proportions, make possible the direct determination of the stress and all panel dimensions required to carry a given intensity of loading with a given skin thickness and effective length of panel.

NACA TN 2459

SOME EFFECTS OF VARYING THE DAMPING IN PITCH AND ROLL ON THE FLYING QUALITIES OF A SMALL SINGLE-ROTOR HELICOPTER. John P. Reeder and James B. Whitten. January 1952. 23p. diagrs., photos., 4 tabs. (NACA TN 2459)

Flight-test measurements and pilots' opinions of the

longitudinal flying qualities and lateral control characteristics of a small single-rotor helicopter are presented in which the damping of the helicopter in pitch and roll was varied by means of a rate sensitive automatic-control device from the amount present in the helicopter with the device inoperative to nearly three times that amount.

NACA TN 2481

HYDRODYNAMIC CHARACTERISTICS OF A LOW-DRAG, PLANING-TAIL FLYING-BOAT HULL. Henry B. Suydam. January 1952. 20p. diagrs., photo., tab. (NACA TN 2481. Formerly RM L7I10)

The hydrodynamic characteristics, as determined from model tests of a planing-tail, flying-boat hull that was found to have very low air drag, are described and these characteristics are compared with the hydrodynamic characteristics of a comparable conventional type of hull. The planing-tail hull was found to have generally greater take-off stability than the conventional type of hull, as well as having improved landing stability. The hydrodynamic resistance was lower for the planing-tail hull than for the conventional type of hull, and the load-resistance ratio was higher for the planing-tail hull.

NACA TN 2483

EFFECT OF FUSELAGE AND TAIL SURFACES ON LOW-SPEED YAWING CHARACTERISTICS OF A SWEPT-WING MODEL AS DETERMINED IN CURVED-FLOW TEST SECTION OF LANGLEY STABILITY TUNNEL. John D. Bird, Byron M. Jaquet and John W. Cowan. October 1951. 19p. diagrs., photo. (NACA TN 2483. Formerly RM L8G13)

Results are presented of a wind-tunnel investigation made to determine the influence of the fuselage and tail surfaces on the rotary derivatives in yawing flight of a transonic-airplane configuration having 45° sweptback wing and tail surfaces. The tests were run in the curved-flow test section of the Langley stability tunnel at a Reynolds number of 1.07×10^{6} and consisted of balance measurements throughout the angle-of-attack range for several flight-path radii of curvature. The results are compared with data from forced-oscillation and free-oscillation tests, and a description of testing techniques used is included.

NACA TN 2485

PILOT ESCAPE FROM SPINNING AIRPLANES AS DETERMINED FROM FREE-SPINNING-TUNNEL TESTS. Stanley H. Scher. October 1951. 36p. diagrs., photos., 4 tabs. (NACA TN 2485. Formerly RM L8D28)

Procedure for pilot escape from spinning airplanes has been determined by means of tests in which pilot escape was simulated from 21 airplane models spinning in the Langley 20-foot free-spinning tunnel. The results in general indicated that the pilot should bail out of the outboard side. Calculated centripetal accelerations acting on the pilot during a spin are presented.

NACA TN 2486

THEORETICAL CHARACTERISTICS OF TWO-DIMENSIONAL SUPERSONIC CONTROL SURFACES. Robert R. Morrissette and Lester F. Oborny. October 1951. 74p. diagrs., tab. (NACA TN 2486. Formerly RM L8G12)

The "Busemann second-order-approximation theory" for the pressure distribution over a two-dimensional airfoil in supersonic flow was used to determine some of the aerodynamic characteristics of uncambered symmetrical parabolic and double-wedge airfoils with leading-edge and trailing-edge flaps. The characteristics presented and discussed in this paper are: flap effectiveness factor, rate of change of hinge-moment coefficient with flap deflection, rate of change of the pitching-moment coefficient about the midchord with flap deflection, and the location of the center of pressure of the airfoil-flap combination.

NACA TN 2488

WIND-TUNNEL INVESTIGATION OF THE CONTRIBUTION OF A VERTICAL TAIL TO THE DIRECTIONAL STABILITY OF A FIGHTER-TYPE AIRPLANE. Alfred A. Marino and N. Mastrocola. January 1952. 41p. diagrs., photo., 4 tabs. (NACA TN 2488. Formerly RM L7K03)

Contributions of vertical tail and fuselage to directional stability are determined from pressure distributions measured over wide ranges of angle of attack and angle of yaw with stabilizer in each of three vertical positions, with stabilizer removed, and with both stabilizer and vertical tail removed. Results point out inadequacies of current design methods and show that more accurate methods must treat separately contributions of vertical tail, fuselage area above stabilizer, and fuselage area below stabilizer.

NACA TN 2504

EFFECTS OF WING POSITION AND HORIZONTAL-TAIL POSITION ON THE STATIC STABILITY CHARACTERISTICS OF MODELS WITH UNSWEPT AND 45° SWEPTBACK SURFACES WITH SOME REFERENCE TO MUTUAL INTERFERENCE. Alex Goodman. October 1951. 58p. diagrs., photos., 4 tabs. (NACA TN 2504)

Results are presented of an investigation made to determine the effects of wing position and horizontal-tail position on the low-speed static lateral and static longitudinal stability characteristics of airplane models having unswept and 45° sweptback surfaces. Interference increments between the various components are evaluated, and efficiency factors of the vertical tail as a function of wing position are presented.

NACA TN 2505

ON THE ATTACHED CURVED SHOCK IN FRONT OF A SHARP-NOSED AXIALLY SYMMETRICAL BODY PLACED IN A UNIFORM STREAM: S. F. Shen and C. C. Lin, Massachusetts Institute of Technology. October 1951. 66p. diagrs. 2 tabs. (NACA TN 2505)

The flow behind the attached curved shock near the nose of an axially symmetrical body placed in a uniform stream is investigated by perturbation from the Taylor-Maccoll conical solution. The first-order perturbation yields the ratio of the initial radii of curvature of the shock and the body. Numerical results are presented for initial semivertex angles of 10°, 20°, and 30°, up to a Mach number around 5. A negative ratio of curvatures is again obtained at low Mach number, as in the two-dimensional case. Higher-order perturbations indicate that a regular shock shape might lead to a logarithmic singularity at the nose of the body.

NACA TN 2507

EXPERIMENTAL INVESTIGATION OF OIL FILM PRESSURE DISTRIBUTION FOR MISALINED PLAIN BEARINGS. G. B. DuBois, H. H. Mabie and F. W. Ocvirk, Cornell University. October 1951. 89p. diagrs., photos., tab. (NACA TN 2507)

Effect of axial and twisting misalining couples on oil film pressure distribution of a loaded bearing was determined. Test data were obtained with a 1.62-by 1.62-inch bearing at a shaft speed of 5000 rpm, a centrally applied load giving 833 pounds per square inch on projected area, and with or without misalining couples. Five three-dimensional plaster models were made to represent the test data obtained under the various conditions. Profile curves of oil film pressure distribution as well as curves showing distribution of bearing temperature are included.

NACA TN 2549

INVESTIGATION OF HYDROCARBON IGNITION. Charles E. Frank and Angus U. Blackham, University of Cincinnati. January 1952. 33p. diagrs., 5 tabs. (NACA TN 2549)

Accurate spontaneous ignition temperatures were determined for over 50 pure organic compounds including paraffins, olefins, aromatic hydrocarbons, alcohols, ethers, and esters. The effects of a wide variety of additives and of eight selected metals on the spontaneous ignition temperatures of these compounds were observed. Results are correlated with chemical structure and with antiknock characteristics where known; the more fundamental aspects of the possible chain-breaking and chain-branching reactions involved are also considered.

NACA TN 2561

A STUDY OF POISSON'S RATIO IN THE YIELD REGION. George Gerard and Sorrel Wildhorn, New York University. January 1952. 30p. diagrs., photos. (NACA TN 2561)

The variation in Poisson's ratio from the elastic to the plastic value was studied experimentally by a systematic series of tests on several aluminum alloys. The tests were conducted under simple tensile and compressive loading along three orthogonal axes. A theoretical variation of Poisson's ratio for an orthotropic solid was obtained from dilatational considerations. The assumptions used in deriving the theory were examined by use of the test data and were found to be in reasonable agreement with experimental evidence.

NACA TN 2570

COMPARISON OF AIRSPEED CALIBRATIONS EVALUATED BY THE ACCELEROMETER AND RADAR METHODS. Lindsay J. Lina and James P. Trant, Jr. January 1952. 16p. diagrs., photos., tab. (NACA TN 2570)

Airspeed calibration of the pitot-static installation on a jet fighter airplane was made to compare the accelerometer method of determining the static-pressure error with the radar method. The tests included shallow dives up to a Mach number of about 0.80 with pull-ups of about 4, 3, and 2g normal acceleration. The results of the test indicated that, for vertical plane maneuvers, the accelerometer method may be used as an alternate to the radar method.

NACA TN 2588

TRANSONIC FLOW PAST A WEDGE PROFILE WITH DETACHED BOW WAVE - DETAILS OF ANALYSIS. Walter G. Vincenti and Cleo B. Wagoner. December 1951. 48p. diagrs., tab. (NACA TN 2588)

Details are given of the calculations of the flow with detached bow wave past a doubly symmetrical, double-wedge profile at zero angle of attack. The results of these calculations have been previously described in NACA TN 2339.

NACA TN 2593

DESIGN OF TWO-DIMENSIONAL CHANNELS WITH PRESCRIBED VELOCITY DISTRIBUTIONS ALONG THE CHANNEL WALLS. I - RELAXATION SOLUTIONS. John D. Stanitz. January 1952. 69p. diagrs., 6 tabs. (NACA TN 2593)

A general method of design is developed for two-dimensional unbranched channels with prescribed velocities as a function of arc length along the channel walls. The method is developed for both incompressible and compressible, irrotational, nonviscous flow. Two types of compressible flow are considered: the general type, with the ratio of specific heats γ equal to 1.4, for example, and the linearized type in which γ is equal to -1.0. The design method gives complete information concerning the flow throughout the channel. Five numerical examples are given including three elbow designs with the same prescribed velocity as a function of arc length along the channel walls but with incom-

pressible, linearized compressible, and compressible flow.

NACA TN 2596

AN IMPULSE-MOMENTUM METHOD FOR CALCULATING LANDING-GEAR CONTACT CONDITIONS IN ECCENTRIC LANDINGS. Robert T. Yntema and Benjamin Milwitzky. January 1952. 60p. diagrs., 3 tabs. (NACA TN 2596)

An impulse-momentum method for determining impact conditions for landing gears in eccentric landings is presented. The analysis is primarily concerned with the determination of landing-gear contact velocities for impacts subsequent to initial touchdown in eccentric landings and with the determination of the effective mass acting on each landing gear. Calculated results are presented which indicate the effects of such factors as landing-gear configuration and location, wing lift, side drift, angle of roll, and initial rolling velocity. A brief study of the effects of variable aerodynamic lift and damping in roll is also presented.

NACA TN 2599

EXPERIMENTAL DETERMINATION OF TIME CONSTANTS AND NUSSELT NUMBERS FOR BARE-WIRE THERMOCOUPLES IN HIGH-VELOCITY AIR STREAMS AND ANALYTIC APPROXIMATION OF CONDUCTION AND RADIATION ERRORS. D. Scadron and Isidore Warshawsky. January 1952. 81p. diagrs., 4 tabs. (NACA TN 2599)

The relations among Nusselt, Reynolds, and Mach numbers for cylinders mounted in cross flow to an air stream, in the ranges $250 <$ Reynolds number $< 30,000$ and $0.1 <$ Mach number < 0.9, have been obtained from experimental determinations of the time constants of bare-wire thermocouples. This information has been used to prepare nomographs for ready computation of approximate values of time constants, radiation errors, and conduction errors for bare cylindrical-wire thermocouples in high-temperature, high-velocity gas streams.

NACA TN 2601

COMPRESSIVE BUCKLING OF SIMPLY SUPPORTED CURVED PLATES AND CYLINDERS OF SANDWICH CONSTRUCTION. Manuel Stein and J. Mayers. January 1952. 34p. diagrs. (NACA TN 2601)

Theoretical solutions are presented for the buckling in uniform axial compression of two types of simply supported curved sandwich plates: the corrugated-core type and the isotropic type. Results are given in the form of equations and curves.

NACA TN 2604

A GENERAL THEORY OF THREE-DIMENSIONAL FLOW IN SUBSONIC AND SUPERSONIC TURBOMACHINES OF AXIAL-, RADIAL-, AND MIXED-FLOW TYPES. Chung-Hua Wu. January 1952. 93p. diagrs., tab. (NACA TN 2604)

Presents a general theory of steady three-dimensional flow of a nonviscous fluid in turbomachines having arbitrary hub and casing shapes and a finite number of blades. Solution of the three-dimensional direct and inverse problem is obtained by investigating an appropriate combination of two-dimensional flows on relative stream surfaces whose intersections with a z-plane either upstream of or somewhere inside the blade row form a circular arc or a radial line. The theory is applicable to both irrotational and rotational absolute flow at the inlet of the blade row and at both design and off-design operations.

NACA TN 2606

SPECTRUM OF TURBULENCE IN A CONTRACTING STREAM. H. S. Ribner and M. Tucker. January 1952. 54p. diagrs., tab. (NACA TN 2606)

Spectrum concepts are employed to study the selective effect of a stream contraction on longitudinal and lateral turbulent velocity fluctuations. By consideration of the effect of stream contraction on a single plane wave, the effect on spectrum and correlation tensors of the turbulence is determined. Weak turbulence and an inviscid fluid are postulated; compressibility of mean flow only is taken into account. For axisymmetric contraction and isotropic initial turbulence, explicit results are obtained. The one dimensional longitudinal spectrum is found to be markedly distorted. The selective effect of contraction on longitudinal and lateral components of turbulence is found to be given uniquely, regardless of details of the isotropic spectrum; comparison with experiment is made.

NACA TN 2609

ESTIMATE OF SLIP EFFECT ON COMPRESSIBLE LAMINAR-BOUNDARY-LAYER SKIN FRICTION. Harold Mirels. January 1952. 22p. diagrs. (NACA TN 2609)

A solution to Rayleigh's problem for a compressible fluid, with slip boundary conditions, has been obtained and related to the flow past a semi-infinite flat plate. The results have been interpreted to define the border region between continuum and slip flow and to estimate the effect of slip.

NACA TN 2610

ONE-DIMENSIONAL COMPRESSIBLE FLOW IN VANELESS DIFFUSERS OF RADIAL- AND MIXED-FLOW CENTRIFUGAL COMPRESSORS, INCLUDING EFFECTS OF FRICTION, HEAT TRANSFER AND AREA CHANGE. John D. Stanitz. January 1952. 61p. diagrs., photo. (NACA TN 2610)

An analysis method and a design method are developed for one-dimensional, compressible flow with friction, heat transfer, and area change in vaneless diffusers with arbitrary profiles in the axial-radial plane. In the analysis method the variations in fluid

properties are determined as a function of radius for a prescribed variation in diffuser wall spacing with radius. In the design method the variation in effective diffuser wall spacing is determined as a function of radius for an arbitrary prescribed variation in one fluid property. As a result of numerical examples it is concluded that: (1) The friction losses in most vaneless diffuser designs are considerable and these losses result from the usually large ratios of wetted surface to flow area in vaneless diffusers. (2) Vaneless diffuser efficiencies can be improved by increased compressor flow rates for a given impeller tip radius.

NACA TN 2611

EXPERIMENTAL INVESTIGATION OF BASE PRESSURE ON BLUNT-TRAILING-EDGE WINGS AT SUPERSONIC VELOCITIES. Dean R. Chapman, William R. Wimbrow and Robert H. Kester. January 1952. 53p. diagrs., photos., tab. (NACA TN 2611)

The pressures acting on the base of blunt-trailing-edge airfoils have been measured at Mach numbers of 1.25, 1.5, 2.0, and 3.1 and at Reynolds numbers from 0.2 to 3.8 million. Data are presented for 29 profiles both with laminar and with turbulent boundary layers approaching the trailing edges of the wings. The base pressure is found to be a function primarily of Mach number and the ratio of the boundary layer thickness at the trailing edge to the trailing-edge thickness.

NACA TN 2615

THE CALCULATED AND MEASURED PERFORMANCE CHARACTERISTICS OF A HEATED-WIRE LIQUID-WATER-CONTENT METER FOR MEASURING ICING SEVERITY. Carr B. Neel, Jr. and Charles P. Steinmetz. January 1952. 59p. diagrs., photos., 6 tabs. (NACA TN 2615)

Initial development has been made of an instrument which could be used to obtain statistical flight data on the liquid-water content of icing clouds and to provide a direct indication of icing severity. The sensing element of the instrument consists of a wire of known temperature-resistance characteristics which is heated by passing electrical current through it. The wire is mounted in the air stream and the degree of cooling resulting from evaporation of impinging water droplets is a measure of the liquid-water content of the cloud. Comparisons are made of the liquid-water content as measured with heated wires and absorbent cylinders in an artificially produced cloud. Performance characteristics of a heated-wire instrument are presented.

NACA TN 2621

DEFLECTION AND STRESS ANALYSIS OF THIN SOLID WINGS OF ARBITRARY PLAN FORM WITH PARTICULAR REFERENCE TO DELTA WINGS. Manuel Stein, J. Edward Anderson and John M. Hedgepeth. February 1952. 53p. photo., diagrs. (NACA TN 2621)

The structural analysis of arbitrary solid cantilever wings by thin-plate theory is reduced to the solution of linear ordinary differential equations by use of the assumption that the chordwise deflections may be expressed in the form of a power series. With the series limited to the first two and the first three terms, the differential equations are solved exactly for several examples of solid delta wings. For cases for which exact solutions to the differential equations cannot be obtained, a numerical procedure is derived. Some experimental data are presented and are found to compare favorably with the present theory.

NACA RM E51J29

PRELIMINARY RESULTS OF CYCLICAL DE-ICING OF A GAS-HEATED AIRFOIL. V. H. Gray, D. T. Bowden and U. von Glahn. January 1952. 38p. photos., diagrs., tab. (NACA RM E51J29)

An NACA 65_1-212 airfoil of 8-foot chord was provided with a gas-heated leading edge for investigations of cyclical de-icing. De-icing was accomplished with intermittent heating of airfoil segments that supplied hot gas to chordwise passages in a double-skin construction. Ice removal was facilitated by a spanwise leading-edge parting strip which was continuously heated from the gas-supply duct. Preliminary results demonstrate that satisfactory cyclical ice removal occurs with ratios of total cycle time to heat-on period from 10 to 26.

NACA RM E51K07

EXPERIMENTAL STUDY OF ISOTHERMAL WAKE-FLOW CHARACTERISTICS OF VARIOUS FLAME-HOLDER SHAPES. George G. Younger, David S. Gabriel and William R. Mickelsen. January 1952. 45p. diagrs., photos., 2 tabs. (NACA RM E51K07)

An investigation of the effects of flame-holder-shape changes on the strength and the shedding frequency of the Kármán vortices was conducted in isothermal flow. Because the characteristics of the stable vortex trail are related to the recirculation zones which influence the combustion process, these results may furnish a basis of correlation of combustion efficiency and stability in combustion studies. Appreciable changes in strength and frequency were obtained by varying flame-holder shape. Changing shape and size provides many schedules of variation of strength and frequency not obtainable by changing size only and may provide theoretical maximum strength for a given frequency.

Royal Aircraft Establishment (Gt. Brit.)
DEVELOPMENT OF ALUMINUM ALLOYS HAVING A HIGH YOUNG'S MODULUS. G. Meikle, J. Thompson and M. E. Whillans. August 1951. 11p. photos., diagr., 4 tabs. (RAE Tech. Note Met.149)

Aluminum alloys containing about 10.5 percent silicon and other elements, having a high Young's modulus have been successfully rolled into sheets (20 SWG - 0.036 in.) under production conditions. Examination of one of the alloys was made at RAE and it was found that the suggested target values of 21 tons/in.^{2}, 0.1 percent proof stress, 28 tons/in.^{2} ultimate tensile stress and 4 percent minimum elongation were met after solution treatment and aging. The average "E" value just fell short of the expected value of 12 x 10^6 lb/in.^{2}, which is 20 percent above that of the normal aircraft aluminum alloys.

DEVELOPMENT OF A HIGH EFFICIENCY AIR LUBRICATED JOURNAL BEARING. E. C. Brown. June 1951. 13p. photos., diagrs. (RAE Tech. Note Aero 2107)

Modifications to the air lubricated drag and side-force bearings of the virtual center balance in the RAE No. 2 (11-1/2 feet by 8-1/2 feet) wind tunnel have resulted in a very substantial increase in their load carrying capacity. A total of eight bearings were affected and all are now working at load coefficients (maximum load carried/projected area of bearing x air supply pressure) of between 0.77 and 0.86, compared with the normally accepted values of 0.3 to 0.4 to this type of bearing. An appendix contains some suggestions for the applications of the principles involved to the design of complete journal bearings.

THE INCOMPRESSIBLE POTENTIAL FLOW PAST TWO-DIMENSIONAL AEROFOILS WITH ARBITRARY SURFACE SUCTION. W. T. Lord. June 20, 1950. 44p. diagrs., tab. (ARC CP 56; ARC 13,196)

The problem of incompressible potential flow past a conventional airfoil which has an arbitrary distribution of normal velocity across its surface is solved by the application of conformal transformation to the solution derived for the corresponding problem for the unit circle. Several simple examples are given. Although it is theoretically possible to obtain any desired tangential velocity distribution on an airfoil by the correct choice of suction velocity distribution, the quantities of suction required are considered large for immediate practical use.

FREE FLIGHT MEASUREMENTS AT SUPERSONIC SPEEDS OF THE DRAG OF A PARTICULAR DELTA WING HAVING A SIMPLE PRESSURE DISTRIBUTION. P. J. Herbert. 1951. 11p. diagrs., photo. (ARC CP 57; ARC 14,008. Formerly RAE Aero 2406)

Squire has drawn attention to a family of delta wings, having airfoil-like sections with a rounded leading edge, whose supersonic wave drag at zero incidence is theoretically determinable, so long as the leading edge is subsonic. Drag measurements have been made, at a Reynolds number of 7 x 10^6, on one member of this family using the ground-launched rocket-boosted model technique. The experimental wave drag is in good agreement with tunnel measurements on another wing of the family, both methods giving values less than theory.

THE MIXING OF CASEIN GLUES. P. M. C. Lacey. November 1951. 8p. diagrs., 2 tabs. (Forest Products Research Lab., AMP 20/2)

In the mixing of prepared casein glues with water, in quantity, difficulties of lump-formation and air-entrainment arise from difficulties experienced by the particles in penetrating the water surface. It is shown that this problem can be solved by carrying out the operation on a continuous basis, and using centrifugal forces to surmerge the particles. A machine has been built in which correctly proportioned streams of casein powder are passed into a specially designed centrifuge cup, continuously discharged at the top through a scoop-tube. A scraper provides reflux near the base, and air is removed centripetally as the materials ascend the divergent walls.

THE DEFORMATION OF SILVER WIRE AT HIGH TEMPERATURE. A. P. Greenough. October 1951. 18p. diagrs., photos., 4 tabs. (RAE Tech. Note Met. 151)

The deformation of silver wires at high temperatures and low stresses has been investigated experimentally. Observations of the behavior of single crystal wires, and on the rate of strain and the development of kinks and necks in polycrystalline wires, provide strong support for Herrig's theory of the mechanism by which the deformation proceeds. Offsetting, or the sliding of grains on their boundaries, takes place in wires subject to low applied stresses, and an explanation of this is proposed. The surface energy of solid silver was estimated from the results obtained.

NACA TN 2519

A COMPARISON OF THE EXPERIMENTAL SUBSONIC PRESSURE DISTRIBUTIONS ABOUT SEVERAL BODIES OF REVOLUTION WITH PRESSURE DISTRIBUTIONS COMPUTED BY MEANS OF THE LINEARIZED THEORY. Clarence W. Matthews. February 1952. 52p. diagrs., tab. (NACA TN 2519. Formerly RM L9F28)

A comparison is made of the theoretical and experimental subsonic compressible pressure-coefficient distributions about several bodies of revolution. The results show that the linearized theory predicts the subsonic pressure coefficients over the central portion of the body. An extrapolation of the theory into the supercritical range does not predict the rearward shift of the negative pressure peak which occurs after the flow becomes critical. Two equations are presented for approximately determining the subsonic compressible pressure-coefficient distributions from the incompressible pressure-coefficient distributions.

EQUAL-STRENGTH DESIGN OF TENSION-FIELD WEBS AND UPRIGHTS. Ralph H. Upson, George M. Phelps and Tung-Sheng Liu, University of Minnesota. January 1952. 46p. diagrs., photos., 4 tabs. (NACA TN 2548)

A method is hereby presented for proportioning thin-web beams to attain equal strength of web and uprights which may in turn be employed toward optimum design of these components. Improved empirical formulas for this purpose are developed and the results checked by experimental loading of six beams. The empirical formulas developed are subject to the limitations of the imposed conditions of this investigation and proportions of uprights as brought out in the experimental results and conclusions.

NACA TN 2602

SURVEY OF THE CHROMIUM-COBALT-NICKEL PHASE DIAGRAM AT 1200° C. W. D. Manly and Paul A. Beck, University of Notre Dame. February 1952. 45p. diagrs., photos., 9 tab. (NACA TN 2602)

A survey of the chromium-cobalt-nickel ternary phase diagram at 1200° C was made by means of microscopic and X-ray diffraction studies on 110 vacuum melted alloys prepared from commercial metals of the highest purity available. At 1200° C, the following phases occur: (1) very extensive face centered cubic solid solutions, based on the binary cobalt-nickel solid solutions; (2) body-centered cubic chromium-base solid solutions; and (3) brittle sigma solid solutions, based on the chromium-cobalt sigma phase which is isomorphous with the iron-chromium sigma phase.

NACA TN 2603

SURVEY OF PORTIONS OF THE COBALT-CHROMIUM-IRON-NICKEL QUATERNARY SYSTEM. E. L. Kamen and Paul A. Beck. February 1952. 62p. photos., diagrs., 13 tabs. (NACA TN 2603)

An isothermal survey was made of certain portions of the chromium-cobalt-nickel-iron quaternary system at 1200° C. The iron content was varied up to 30 percent to include the range of commercial chromium-cobalt-nickel alloys. The component cobalt-chromium-iron ternary system was also studied.

NACA TN 2607

ELECTRICAL PRESSURE INTEGRATOR. Arleigh P. Helfer. January 1952. 44p. photos., diagrs., 2 tabs. (NACA TN 2607)

The design of an instrument that is capable of integration of airfoil pressures into a quantity representative of normal force and pitching moment acting on an airfoil is presented. Flight and wind-tunnel versions of this instrument are described along with samples of test data obtained from them.

NACA TN 2608

CHARTS AND APPROXIMATE FORMULAS FOR THE ESTIMATION OF AEROELASTIC EFFECTS ON THE LOADING OF SWEPT AND UNSWEPT WINGS. Franklin W. Diederich and Kenneth A. Foss. February 1952. 98p. diagrs., 3 tabs. (NACA TN 2608)

Charts are presented for the estimation of aeroelastic effects on spanwise lift distribution, lift-curve slope, aerodynamic center, and damping in roll of swept and unswept wings at subsonic and supersonic speeds. Some design considerations brought out by the results of this paper are discussed.

*AVAILABLE ON LOAN ONLY.

NACA TN 2616

THE ACHIEVEMENT OF CONTINUOUS WALL CURVATURE IN DESIGN OF TWO-DIMENSIONAL SYMMETRICAL SUPERSONIC NOZZLES. J. C. Evvard and Lawrence R. Marcus. January 1952. 8p. diagrs. (NACA TN 2616)

Auxiliary boundary conditions were derived to assure continuity of wall curvature in applying the method of characteristics to the design of two-dimensional supersonic nozzles.

NACA TN 2617

RELATIVE IMPORTANCE OF VARIOUS SOURCES OF DEFECT-PRODUCING HYDROGEN INTRODUCED INTO STEEL DURING APPLICATION OF VITREOUS COATINGS. Dwight G. Moore, Mary A. Mason and William N. Harrison, National Bureau of Standards. February 1952. 31p. photos., diagrs., 5 tabs. (NACA TN 2617)

The purpose of this investigation was to study and to determine experimentally the relative importance of various sources of defect-producing hydrogen introduced into steel during the application of vitreous-type ceramic coatings. Under the conditions investigated, the principal source of defect-producing hydrogen was the dissolved water present in the enamel frit of the coating. Acid pickling, milling water, chemically combined water in the clay, and quenching water were all minor sources. Test results indicate that fishscaling, reboil, and possibly primary boil may be eliminated by using a coating prepared with a water-free frit.

NACA TN 2618

CREEP IN METALS. A. D. Schwope, F. R. Shober and L. R. Jackson, Battelle Memorial Institute. February 1952. 52p. diagrs., photos., tab. (NACA TN 2618)

This report covers phases of an investigation of the fundamentals of creep in metals. Results of a study of creep in single crystals of high-purity aluminum are presented and discussed. It is shown that at low stresses the creep phenomenon appears to be consistent with Mott and Nabarro's theory of exhaustion creep while at higher stresses results appear to be more in accord with ideas expressed by Andrade.

NACA TN 2622

A DESCRIPTION AND A COMPARISON OF CERTAIN NONLINEAR CURVE-FITTING TECHNIQUES, WITH APPLICATIONS TO THE ANALYSIS OF TRANSIENT-RESPONSE DATA. Marvin Shinbrot. February 1952. 41p. diagrs., 5 tabs. (NACA TN 2622)

Several least-squares methods for curve fitting a set of data to a nonlinear function are described and compared. Each of the methods is applied to fit data, obtained from a flight test of an actual airplane, to a sum of two exponentials, thus illustrating the use of the methods for the calculation of aircraft stability parameters.

NACA TN 2627

COINCIDENCE METHOD APPLIED TO ION BEAM MEASUREMENT. Stanley Fultz and M. L. Pool. Ohio State University. February 1952. 13p. diagrs. (NACA TN 2627)

A coincidence Geiger counter system was constructed for the absolute measurement of the activity of radioactive substances made in a cyclotron. The average beam current in the cyclotron can be calculated from the number of disintegrations per second observed, the half-life of the radioactive substance, and the reaction cross section.

NACA TN 2628

BONDING OF MOLYBDENUM DISULFIDE TO VARIOUS MATERIALS TO FORM A SOLID LUBRICATING FILM. I - THE BONDING MECHANISM. Douglas Godfrey and Edmond E. Bisson. February 1952. 16p. photos., 4 tabs. (NACA TN 2628)

The use of molybdenum disulfide MoS_2 as a solid film lubricant in applications where designs or temperatures preclude liquid lubricants is dependent upon successful bonding of MoS_2 to the surface. An experimental investigation was conducted to determine the basic mechanism of bonding MoS_2 and extend application of the bonding to a variety of materials. When MoS_2 was applied to a surface as a mixture of MoS2 powder and some liquid vehicles, the liquid vehicle decomposed and polymerized to a resin which bound the particles of MoS_2 together and to the surface to be lubricated. MoS_2 can be bonded by resin-forming viscous liquid vehicles, such as asphalt- and silicone-base varnishes, glycerine, ethylene glycol, polyglycol ether, and corn syrup to a variety of materials, such as steel, aluminum, brass, stainless steel, and glass. The reduction of Fe_2O_3, formed by preheating steel in air, to Fe_3O_4 by one of the liquid vehicles (syrup) improves the frictional properties of the solid lubricating film. Rubbing of MoS_2 whether dusted, built-up, or bonded by a resin to a surface produced distinct preferred orientation.

NACA TN 2629

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF FULLY DEVELOPED TURBULENT FLOW OF AIR IN A SMOOTH TUBE WITH HEAT TRANSFER WITH VARIABLE FLUID PROPERTIES. R. G. Deissler and C. S. Eian. February 1952. 43p. diagrs. (NACA TN 2629)

A previous analysis of turbulent flow and heat transfer in smooth tubes with variable fluid properties was modified in order to be applicable to air which has a Prandtl number slightly less than unity (0.73). In order to verify the analysis, tests were conducted to determine local heat-transfer coefficients and friction factors for fully developed turbulent flow of air in a smooth electrically heated tube having an inside diameter of 0.87 inch and a length of 87 inches. The tests were conducted at high ratios of wall to fluid bulk temperature. Velocity and temperature

profiles were measured for some conditions. The analytically predicted results were found to agree closely with the experimental results.

NACA TN 2631

THE SIMILARITY LAW FOR NONSTEADY HYPERSONIC FLOWS AND REQUIREMENTS FOR THE DYNAMICAL SIMILARITY OF RELATED BODIES IN FREE FLIGHT. Frank M. Hamaker and Thomas J. Wong. February 1952. 24p. diagrs. (NACA TN 2631)

The hypersonic similarity law for steady flow is extended to include nonsteady flows. The aerodynamic forces are correlated by this law and this correlation is used to derive conditions for dynamical similarity of the motions of related bodies in free flight. The correlation of flight paths was achieved on this basis.

NACA TN 2634

EVALUATION OF THREE METHODS FOR DETERMINING DYNAMIC CHARACTERISTICS OF A TURBOJET ENGINE. Gene J. Delio. February 1952. 56p. diagrs., 6 tabs. (NACA TN 2634)

Data resulting from approximate step and sinusoidal disturbances of fuel flow of a turbojet engine were analyzed by three methods: approximate indicial responses were used in determining the coefficients of differential equations, Fourier analysis was performed on the transient data, and AC analysis was performed using steady-state frequency response data. Transfer functions are derived from functional relationships describing turbojet engine dynamic behavior resulting from changes of several manipulated variables. Engine nonlinearities and supply source regulation are considered.

NACA RM E51J30

PRELIMINARY INVESTIGATION OF CYCLIC DE-ICING OF AN AIRFOIL USING AN EXTERNAL ELECTRIC HEATER. James P. Lewis and Dean T. Bowden. February 1952. 43p. photos., diagrs. (NACA RM E51J30)

An investigation was conducted in the NACA Lewis icing research tunnel to determine the characteristics and requirements of cyclic de-icing of an airfoil by use of an external electric heater. The present investigation was limited to an airspeed of 175 miles per hour. Data are presented to show the effects of variations in heat-on and heat-off periods, ambient air temperature, liquid-water content, angle of attack and heating distribution on the requirements for cyclic de-icing. The external heat flow at various icing and heating conditions is also presented. A continuously heated parting strip at the airfoil leading edge was found necessary for quick, complete, and consistent ice removal. The cyclic power requirements were found to be primarily a function of the datum temperature and heat-on time, with the other operating and meteorological variables having a second-order effect. Short heat-on periods and high power densities resulted in the most efficient ice removal, the minimum energy input, and the minimum runback ice formations.

NACA TM 1300

WIND-TUNNEL CORRECTIONS AT HIGH SUBSONIC SPEEDS PARTICULARLY FOR AN ENCLOSED CIRCULAR TUNNEL. (Windkanalkorrekturen bei hohen Unterschallgeschwindigkeiten unter besonderer Berücksichtigung des geschlossenen kreiskanals). B. Göthert. February 1952. 43p. diagrs., 3 tabs. (NACA TM 1300. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1216; Deutsche Versuchsanstalt für Luftfahrt E. V., Berlin. Institut für Aerodynamik, May 16, 1940).

A review of existing publications on wind-tunnel corrections is followed by an approximate method for determining the corrections due to model and wake displacement and to lift. Relations are investigated for fuselages and wings of various spans in closed circular tunnels. A comparison is made between the computations and the tests in the DVL high-speed wind tunnel.

NACA TM 1328

CONCERNING THE FLOW ABOUT RING-SHAPED COWLINGS. PART VIII - FURTHER MEASUREMENTS ON ANNULAR PROFILES. (Über die Strömung an ringförmigen Verkleidungen. VIII Mitteilung: Weitere Messungen an Ringprofilen). Dietrich Küchemann and Johanna Weber. February 1952. 11p. diagrs. (NACA TM 1328. Trans from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1236/8, March 25, 1943).

The measurements of part V (reference 1) of this series of reports, which concerned comparatively long ring profiles, are supplemented by measurements on shorter rings as they are used for shrouded propellers and cowlings of ring-shaped radiators. Mass-flow coefficients and profile drags are given. Furthermore, it has to be determined how far the potential theory describes the flow phenomenon with sufficient accuracy and whether the present theory for the calculation of thin annular profiles yields useful profile forms and is suitable for determination of the mass flow for thick profiles.

College of Aeronautics, Cranfield (Gt. Brit.)
THE MEASUREMENT OF THE DERIVATIVE Z_w FOR AN OSCILLATING AEROFOIL. A. L. Buchan, K. D. Harris and P. M. Somervail. June 1950. 32p. diagrs. (College of Aeronautics, Cranfield. Rept. 40)

Presents results of experimental measurements of the damping derivative coefficient for constant chord rigid wings of various aspect ratios having sweepback angles of zero and 45°. The results for the rectangular wings show substantial agreement with the unsteady airfoil theory developed by W. P. Jones. The dependence of W_z upon frequency parameter is as given by theory and is much less than for two-dimensional flow, but the numerical results are approximately 10 percent below the theoretical. The effect of sweepback is to decrease the numerical value, but this effect is more pronounced for low than for high aspect ratios.

SANDWICH CONSTRUCTION - A PRACTICAL APPROACH FOR THE USE OF DESIGNERS. D. Williams. 1951. 25p. diagrs. (ARC R & M 2466; ARC 10,384. Formerly RAE Structures 2)

Formulas for the design of sandwich panels are derived. The approximations used reduce the accuracy of the results to only a negligible degree. The qualities both of stiffness and strength desirable in core materials (homogeneous or grained) are discussed, and suggestions for future developments are made. It is shown that very high efficiencies are obtainable with a core material having elastic moduli some 500 less than those of dural, even though the density may be as much as 1/100 that of duralumin.

AN INVESTIGATION IN FLIGHT OF THE INDUCED VELOCITY DISTRIBUTION UNDER A HELICOPTER ROTOR WHEN HOVERING. P. Brotherhood. 1951. 16p. photos., diagrs. (ARC R & M 2521. Formerly RAE Aero 2212; ARC 10,838; ARC H58)

Flight tests have been made on a Sikorsky R-4B helicopter to determine the distribution of the velocity induced by the rotor in hovering flight. Measurements in the fully developed slipstream were referred back to their appropriate disk positions by means of smoke visualization of the streamlines. The experimental distribution agrees very well with that predicted by propeller strip theory, provided the tip loss is taken into account.

THE BEHAVIOUR IN COMPRESSION OF ALUMINIUM ALLOY PANELS HAVING A FLAT SKIN WITH CORRUGATED REINFORCEMENT. E. A. Brook. 1951. 33p. diagrs., photos., 8 tabs. (ARC R & M 2598; ARC 9013. Formerly RAE SME 3333)

This describes tests on 36 panels. Each panel consisted of a flat skin reinforced with continuous corrugations, and the object of the test was to investigate the effect of rivet pitch and arrangement, corrugation width, and skin and corrugation thickness on the buckling and failing loads of the panels. The results indicate that for the thickness of skin and corrugations considered, the interrivet buckling stress

is considerably less than the stress at which the skin between rivets would buckle, when considered as an Euler strut with encastre ends.

Aeronautical Research Council (Gt. Brit.)
STRESS DIFFUSION ADJACENT TO GAPS IN THE INTER-SPAR SKIN OF A STRESSED-SKIN WING. M. Fine and H. G. Hopkins. 1951. 13p. diagrs. (ARC R & M 2618; ARC 5941. Formerly RAE SME 3208)

This report gives, subject to certain simplifications, a theoretical analysis of the problem of stress concentrations due to cut-outs and gaps in the wing surface. Approximate formulas are found for the direct stress in the flanges and the shear stress in the skin at the flanges and at the chordwise gap. A numerical example to illustrate the application to design is given. Although various factors are likely to reduce the stress concentration if the present calculations predict it to be high, some reinforcement of the skin is likely to be necessary.

EVAPORATION FROM THE SURFACE OF A BODY IN AN AIRSTREAM. (WITH PARTICULAR REFERENCE TO THE CHEMICAL METHOD OF INDICATING BOUNDARY LAYER TRANSITION.) P. R. Owen and A. O. Ormerod. September 1951. 61p. diagrs. (RAE Aero 2431)

The problem of predicting the rate of transport of a gas from or into the surface of a two-dimensional body in an air stream is discussed. The principal object of the investigation is to provide a means of estimating the time required to obtain an experimental record of boundary layer transition when a chemical technique is used. The methods evolved should, however, find an application to other forced diffusion phenomena. Experimental results are compared with theoretical ones. A calculation of the effect of altitude is made.

Royal Aircraft Establishment (Gt. Brit.)
CALCULATION OF THE PRESSURE DISTRIBUTION OVER A WING AT SONIC SPEEDS. K. W. Mangler. September 1951. 94p. diagrs., 3 tabs. (RAE Aero 2439)

A method is developed for the calculation of the pressure distribution and the aerodynamic forces and moments acting on a wing at incidence, in steady roll, and in steady pitch. The calculation assumes an inviscid potential flow and is restricted to small incidence and thickness ratio. Calculations indicate the plan form is as important to pressure distribution at sonic speeds as the chordwise section is at subsonic speeds for wings of larger aspect ratios. Although the calculation is based in the assumption of an inviscid flow without shock waves, the results are thought to be useful for showing the main trends of the behavior of a wing near sonic speed.

N-13369*

CONTRIBUTION TO THE NONSTEADY LAMINAR BOUNDARY LAYER ON PLANE WALLS. (Beitrag zur instationären laminaren Grenzschicht an ebenen Wänden). W. Wuest. January 1952. 14p. diagrs. (Trans from Ingenieur-Archiv, v. 17, no. 3, 1949, p. 193-198).

The development of a laminar boundary layer is investigated in the neighborhood of plane walls or at the contact surface of two fluids. Aside from dependence

on time, a dependence on distance from the wall is assumed. Also investigated is a nonsteady analogue to the boundary layer suction in the steady case which is dependent upon distance along the wall. The flow at the contact surface between two fluids of different density and velocity is discussed. The results show that the ratio of the contact-surface velocity and the velocity outside of the boundary layer is independent of time.

N-10898*

APPLICATION OF THIN-WING EXPANSION METHOD TO GAS FLOW ALONG SINUSOIDAL WALL. (Seigempakei no Kabe ni Ou Kosokikiryu ni Tsuite). Isao Imai and Seiichi Oyama. 16p. diagrs. (Trans. from Tokyo (Imperial) Univ., Institute of Science and Technology, Reports, v. 2, no. 3-4, Mar.-Apr., 1948, p. 39-44).

To investigate a high velocity fluid the thin-wing expansion method carried to the third approximation was applied to flow along a sinusoidal wall. By varying ϵ and M the flow conditions could be studied. Because the factor μ^3 is involved as the approximation is carried further, it is difficult to predict anything definite for the case M near 1. According to numerical results a continuous solution exists for the case of a supersonic zone; but the curvature of the velocity distribution curves at the points of maximum velocity becomes infinite, shock waves arise, and the convergence of the solution is disrupted.

National Advisory Committee for Aeronautics. THE ROLE OF PHYSICS IN AERONAUTICAL DEVELOPMENT. Hugh L. Dryden. 56p. photos., diagrs. (Presented before American Association for the Advancement of Science, at conference on Applied Physics, Municipal Auditorium, Philadelphia, December 27, 1951).

In order to stimulate the physicist's interest in the field of aeronautics a few examples are given of the applications of existing physical knowledge, of problems in physics arising from the resolution of engineering problems into their component subproblems, and of the great indebtedness of aeronautics to physics for its tools of measurement. For security reasons and to fulfill better the aims of the paper, emphasis has been placed on the longer range problems.

DECLASSIFIED NACA REPORTS

NACA RM E8A29a

INTERNAL-FILM COOLING OF ROCKET NOZZLES. J. L. Sloop and George R. Kinney. June 8, 1948. 40p. diagrs., photos. (NACA RM E8A29a) (Declassified from Restricted, 1/3/52)

Experiments were conducted with a 1000-pound-thrust rocket engine to determine the feasibility of cooling convergent-divergent nozzles by internal film of water introduced at nozzle entrance. Water flow of 3 percent of propellant flow reduced heat flow into nozzle to 55 percent of uncooled heat flow. Introduction of water by porous ring before the nozzle resulted in more uniform coverage of nozzle than water introduced by single arrangement of 36 jets directed along nozzle wall. Water flow through a porous ring of 3.5 percent of propellant flow stabilized wall temperature in convergent section but did not adequately cool throat or divergent sections.

NACA RM E8F01

PHOTOGRAPHIC STUDY OF COMBUSTION IN A ROCKET ENGINE. I - VARIATION IN COMBUSTION OF LIQUID OXYGEN AND GASOLINE WITH SEVEN METHODS OF PROPELLANT INJECTION. Donald R. Bellman and Jack C. Humphrey. August 26, 1948. 51p. photos., diagrs., tab. (NACA RM E8F01) (Declassified from Restricted, 1/3/52)

Motion pictures up to 3000 frames per second were taken of the combustion of liquid oxygen and gasoline in a 100-pound thrust rocket engine. The effect of seven methods of propellant injection on the uniformity of combustion was investigated. The flame front was generally found to extend to the injector faces and all the injection systems showed considerable nonuniformity of combustion. Pressure vibration records indicated combustion vibrations that corresponded to resonant-chamber frequencies.

NACA RM E50F19

INTERNAL-FILM-COOLING EXPERIMENTS IN 4-INCH DUCT WITH GAS TEMPERATURES TO 2000° F. George R. Kinney and John L. Sloop. September 21, 1950. 34p. diagrs., tab. (NACA RM E50F19) (Declassified from Restricted, 1/3/52)

An investigation of film cooling was conducted in a 4-inch-diameter duct at gas temperatures from 600° to 2000° F and Reynolds numbers from 400,000 to 1,400,000. The coolants were water and ethylene glycol at flows of 1 to 6 percent of the gas flow. During vaporization of the liquid film, coolants kept the duct wall below the boiling temperature of the liquid; little additional duct cooling was obtained from coolant vapor alone. Data were generalized over part of the coolant-flow range by use of heat-transfer relations in a form that facilitates prediction of coolant flow required to film-cool a duct for a desired length when temperature and flow of the hot gas are known.

NACA RM E51C13

INVESTIGATION OF ANNULAR LIQUID FLOW WITH COCURRENT AIR FLOW IN HORIZONTAL TUBES. George R. Kinney and Andrew E. Abramson. May 25, 1952. 33p. diagrs., photos., 2 tabs. (NACA RM E51C13) (Declassified from Restricted, 1/3/52)

Visual observations and flow analyses were made of annular liquid flow with cocurrent air flow in horizontal tubes. Experiments were conducted with air temperatures of 80°, 475°, and 800° F, air-stream Reynolds numbers from 410,000 to 2,900,000, and liquid flows from 0.3 to 21 percent of air flows. Annular liquid films were approximately 0.0005 to 0.005 inch thick. Film surface changed from relatively smooth with the liquid annulus in the region where viscous forces are appreciable to disturbed where turbulent forces are predominant. Change in cooling effectiveness of liquid films in film-cooling experiments was related to film-surface change; surface condition could be predicted approximately knowing liquid flow and viscosity.

NACA RM L8D01

AERODYNAMIC CHARACTERISTICS OF A TWO-BLADE NACA 10-(3)(12)-03 PROPELLER. W. H. Gray and A. E. Allis. August 30, 1948. 27p. diagrs., tab. (NACA RM L8D01) (Declassified from Restricted, 12/28/51)

Contains results of wind-tunnel tests of the NACA 10-(3)(12)-03 propeller. The particular blade design, the tests of which are described, was one necessary to the investigation of the effect of differences in blade-thickness ratios. A maximum efficiency of 0.91 was attained at a constant rotational speed of 1140 rpm. Peak efficiency, at a blade angle of 45°, was decreased 26 percent by a helical tip Mach number increase from 0.81 to 1.10.

CURRENT NACA REPORTS

NACA Rept. 1015

ANALYSIS OF TURBULENT FREE-CONVECTION BOUNDARY LAYER ON FLAT PLATE. E. R. G. Eckert and Thomas W. Jackson. 1951. 7p. diagrs. (NACA Rept. 1015. Formerly TN 2207)

A calculation was made for the flow and heat transfer in the turbulent free-convection boundary layer on a vertical flat plate. Formulas for the heat transfer coefficient, boundary layer thickness, and the maximum velocity in the boundary were obtained.

NACA Rept. 1017

INVESTIGATION OF FREQUENCY-RESPONSE CHARACTERISTICS OF ENGINE SPEED FOR A TYPICAL TURBINE-PROPELLER ENGINE. Burt L. Taylor, III and Frank L. Oppenheimer. 1951. 11p. diagrs., 2 tabs. (NACA Rept. 1017. Formerly TN 2184)

Experimental frequency-response characteristics of engine speed for a typical turbine-propeller engine are presented. Correlation is made between these experimental data and analytical frequency-response characteristics. Results of this investigation indicate that engine speed is a linear function of fuel flow and propeller-blade angle for small variations of these parameters. Approximate frequency-response characteristics may be calculated from solutions of a linear differential equation and equilibrium torque characteristics of the engine and the propeller.

NACA TN 2526

DETERMINATION OF RAM-JET COMBUSTION-CHAMBER TEMPERATURES BY MEANS OF TOTAL-PRESSURE SURVEYS. I. Irving Pinkel. December 1951. 10p. diagrs., tab. (NACA TN 2526. Formerly RM E7C03)

A method is described by which the total temperature of the gases at the combustion-chamber outlet of a ram-jet engine may be determined from the loss in total pressure measured across the combustion chamber. A working chart is presented by means of which the ratio of the total temperature of the gases at the combustion-chamber outlet to the total temperature of the gases at the combustion-chamber inlet may be determined from the measured loss of total pressure across the combustion chamber and the known values of air flow, total pressure, and total temperature at the combustion-chamber inlet.

NACA TN 2571

APPLICATION OF THE VON KÁRMÁN MOMENTUM THEOREM TO TURBULENT BOUNDARY LAYERS. Jerold M. Bidwell. December 1951. 25p. diagrs. (NACA TN 2571)

A study is made of the Von Kármán momentum theorem with respect to its application to turbulent boundary layers in a positive pressure gradient. Data were obtained from Schubauer and Klebanoff (NACA TN 2133) and Ludwieg and Tillman (NACA TM 1285) with which both the terms due to the mean flow and the terms due to the fluctuating flow could be evaluated.

NACA TN 2585

CALCULATION OF AERODYNAMIC FORCES ON A PROPELLER IN PITCH OR YAW. John L. Crigler and Jean Gilman, Jr. January 1952. 33p. diagrs. (NACA TN 2585. Formerly RM L8K26)

An analysis was made to determine the applicability of existing propeller theory and the theory of oscillating airfoils to the problem of determining the magnitude of the forces on propellers in pitch or yaw. Strip calculations using compressible airfoil characteristics were first made as though steady-state conditions existed successively at several blade positions of the propeller blades during one revolution. A theory of oscillating airfoils in pulsating incompressible potential flow was then considered from which it was possible to determine factors which would modify the steady-state forces.

NACA TN 2590

CALCULATIONS ON THE FORCES AND MOMENTS FOR AN OSCILLATING WING-AILERON COMBINATION IN TWO-DIMENSIONAL POTENTIAL FLOW AT SONIC SPEED. Herbert C. Nelson and Julian H. Berman. January 1952. 36p. diagrs., 2 tabs. (NACA TN 2590)

The linearized theory for compressible unsteady flow is used, as suggested in recent contributions to the subject, to obtain the velocity potential and the lift and moment for a thin, harmonically oscillating, two-dimensional wing-aileron combination moving at

AVAILABLE ON LOAN ONLY.

E REPORT TITLE AND AUTHOR.

sonic speed. The velocity potential is derived by considering the sonic case as the limit of the linearized supersonic theory. The paper provides extensive tables of numerical values for the coefficients contained in the expressions for lift and moment, for various values of the reduced frequency $k(0 < k \leq 3.5)$ and aileron hinge position (from 10 to 90 percent of the wing chord).

NACA TN 2591

THE EFFECTS OF REYNOLDS NUMBER ON THE APPLICATION OF NACA 16-SERIES AIRFOIL CHARACTERISTICS TO PROPELLER DESIGN. Harold E. Cleary. January 1952. 15p. diagrs. (NACA TN 2591. Formerly RM L7H12)

An analysis has been made of airfoil data taken on several NACA 16-series propeller airfoils. This analysis has shown that the combined effects of Reynolds number changes and variations in airfoil characteristics resulting from differences in models and tunnels are such that when 5-inch-chord and 12-inch-chord data are applied to full-scale propeller design at or near the design condition, differences of less than 1 percent in efficiency are involved.

NACA TN 2592

ORIENTATION OF ORIFICES ON BODIES OF REVOLUTION FOR DETERMINATION OF STREAM STATIC PRESSURE AT SUPERSONIC SPEEDS. Morton Cooper and Clyde V. Hamilton. January 1952. 26p. diagrs., photo., tab. (NACA TN 2592)

Experimental pressures obtained on a parabolic body of revolution of large fineness ratio at a Mach number of 1.59 and a Reynolds number of 3.6×10^6 have been analyzed in order to locate positions at which static-pressure orifices will indicate the stream static pressure independent of the pitch-yaw attitude of the body.

NACA TN 2594

INVESTIGATION OF THE STRUCTURAL DAMPING OF A FULL-SCALE AIRPLANE WING. Dwight O. Fearnow. February 1952. 11p. diagrs., photo., tab. (NACA TN 2594. Formerly RM L51A04)

An investigation to determine the structural damping characteristics of a full-scale airplane wing was conducted by the shock-excitation method wherein the wing was loaded to a predetermined deflection and the load suddenly released. The test specimen vibrated at its fundamental bending frequency of 1.69 cycles per second. Only the first 2 or 3 cycles showed any indication of a higher frequency being superimposed upon the fundamental bending frequency. The damping was found to increase from about 0.002 of critical at an amplitude of vibration of ±0.05 inch to approximately 0.006 of critical at an amplitude of ±5 inches.

NACA TN 2600

STRESSES AND DEFORMATIONS IN WINGS SUBJECTED TO TORSION. B. F. Ruffner and Eloise Hout, Oregon State College. February 1952. 79p. diagrs., 23 tabs. (NACA TN 2600)

Basic equations of Kármán and Chien are solved by representing the shape of a torsion box by means of a Fourier series. Coefficients of the series are determined by conventional methods. Angles of twist, longitudinal stresses, and shear stresses are determined in terms of the series coefficients. The method is applied to the calculation of angles of twist and stresses in torsion boxes of rectangular, elliptical, and airfoil cross section. Results obtained for angles of twist and normal stresses are in good agreement with results of Kármán and Chien except at sharp corners. Results obtained for shear stresses indicate the necessity for use of a large number of terms of the series for satisfactory accuracy.

NACA TN 2619

SOME REMARKS ON AN APPROXIMATE METHOD OF ESTIMATING THE WAVE DRAG DUE TO THICKNESS AT SUPERSONIC SPEEDS OF THREE-DIMENSIONAL WINGS WITH ARBITRARY PROFILE. Kenneth Margolis. February 1952. 9p. (NACA TN 2619)

A semiempirical profile-correction factor is discussed which enables the estimation of the wave-drag coefficient due to thickness at supersonic speeds for three-dimensional wings with arbitrary airfoil section (subject to restrictions of the thin airfoil theory) through use of previously calculated or known drag coefficients.

NACA TN 2620

PRINCIPLE AND APPLICATION OF COMPLEMENTARY ENERGY METHOD FOR THIN HOMOGENEOUS AND SANDWICH PLATES AND SHELLS WITH FINITE DEFLECTIONS. Chi-Teh Wang, New York University. February 1952. 33p. diagrs. (NACA TN 2620)

The principle of complementary energy in the nonlinear elasticity theory is shown to be derivable from the principle of potential energy by a Legendre type of transformation. In particular, the expression of the complementary energy is derived for homogeneous and sandwich plates and shells with large deflections. By the method of complementary energy, the stress-strain relations are derived for homogeneous shells, sandwich plates, and sandwich shells.

NACA TN 2626

AN INVESTIGATION OF BENDING-MOMENT DISTRIBUTION ON A MODEL HELICOPTER ROTOR

BLADE AND A COMPARISON WITH THEORY. John R. Meyer, Jr., Massachusetts Institute of Technology. February 1952. 91p. diagrs., photos., 12 tabs. (NACA TN 2626)

Bending-moment distributions were measured on a model helicopter rotor blade under hovering and simulated forward-flight conditions. The hinged-blade configuration was tested up to an advance ratio μ of 0.50; the fixed-at-root configuration, up to $\mu = 0.90$. Curves of maximum-bending-moment distribution are presented for all test conditions. Harmonic bending moments were found from a harmonic analysis of data for $\mu = 0.22$ and 0.47. Theoretical calculations at $\mu = 0.22$ and 0.47 for hinged- and fixed-at-root conditions, respectively, are compared with experimental results and the agreement is reasonable. Experimentally determined resonance peaks are compared with those indicated by theory for three sets of blades of different stiffnesses. Aerodynamic-loading expressions which include the effect of elastic flapping are developed for the fixed-at-root blade and are used in the Goodyear method which is modified for the fixed-at-root condition.

NACA TN 2630

A SOLUTION OF THE NAVIER-STOKES EQUATION FOR SOURCE AND SINK FLOWS OF A VISCOUS HEAT-CONDUCTING COMPRESSIBLE FLUID. Robert V. Hess. February 1952. 60p. diagrs., tab. (NACA TN 2630)

A solution of the Navier-Stokes equation for source and sink flows of a viscous, heat-conducting, compressible fluid is given for the case of constant total flow energy. For the satisfaction of the condition of constant total flow energy, a certain Prandtl number is required. Aside from this more obvious requirement, the selection of a certain ratio of the first and second viscosity coefficient is necessary. The nature of the general solutions for flow with arbitrary Prandtl number and with heat addition is discussed. Furthermore, the manner is discussed in which the familiar heat-conduction effects combined with the peculiar viscous effects solely due to compressibility, sometimes called the longitudinal viscous effects, influence the flow through a curved minimum section joined to a sink flow. A discussion of the second viscosity coefficient from the gas-dynamic approach is also given.

NACA TN 2633

ESTIMATION OF THE MAXIMUM ANGLE OF SIDESLIP FOR DETERMINATION OF VERTICAL-TAIL LOADS IN ROLLING MANEUVERS. Ralph W. Stone, Jr. February 1952. 46p. diagrs., 4 tabs. (NACA TN 2633)

This paper presents the results of a study, by a step-by-step integration of the equations of motion, of the variations of angle of sideslip and angle of attack in rolling maneuvers, particularly for airplanes with mass distributed mainly along the fuselage. The results are compared with those of existing methods for estimating angles of sideslip for determining vertical-tail loads in rolling maneuvers.

NACA TN 2635

AN ANALYSIS OF LAMINAR FREE-CONVECTION FLOW AND HEAT TRANSFER ABOUT A FLAT PLATE PARALLEL TO THE DIRECTION OF THE GENERATING BODY FORCE. Simon Ostrach. February 1952. 47p. diagrs., tab. (NACA TN 2635)

A formal and general analysis of the free-convection flow about a flat plate parallel to the direction of the generating body force is made, and velocity and temperature distributions for Prandtl numbers of 0.01, 0.72, 0.733, 1, 2, 10, 100, 1000, and large Grashof numbers are computed. The distributions for Prandtl number of 0.72 compare favorably with experimental values. It is shown that velocities and Nusselt numbers of the same order of magnitude as those associated with forced-convection flows can be obtained under free-convection conditions. A flow and a heat-transfer parameter are derived from which the important physical quantities can be computed. Reasonable agreement is obtained among values of the heat-transfer parameter obtained from an approximate theoretical development, experiments, and the present development.

NACA TN 2636

INFLUENCE OF LUBRICANT VISCOSITY ON OPERATING TEMPERATURES OF 75-MILLIMETER-BORE CYLINDRICAL-ROLLER BEARING AT HIGH SPEEDS. E. Fred Macks, William J. Anderson and Zolton N. Nemeth. February 1952. 47p. diagrs., photo., 3 tabs. (NACA TN 2636)

Oil viscosity (five oils were used) was found to have a significant effect on bearing operating temperature. Minimum bearing temperatures result when a low viscosity, low viscosity-index oil is used. Minimum power rejection to the oil (at a constant bearing temperature) results when a low viscosity oil is introduced at high inlet temperatures. The cooling correlation previously developed was extended to include fully the effect of varying viscosity. It is therefore possible to predict either inner-race or outer-race bearing temperature from single curves regardless of whether speed, load, oil flow, oil inlet temperature, oil inlet viscosity, oil-jet diameter or any combination of these parameters is varied.

NACA TN 2637

COMPRESSIVE BUCKLING OF FLAT RECTANGULAR METALITE TYPE SANDWICH PLATES WITH SIMPLY SUPPORTED LOADED EDGES AND CLAMPED UNLOADED EDGES. (Revised) Paul Seide. February 1952. 27p. diagrs., 3 tabs. (NACA TN 2637) (Superseded TN 1886, May 1949)

A theoretical solution is obtained for the problem of

the compressive buckling of flat rectangular Metalite-type sandwich plates with simply supported loaded edges and clamped unloaded edges. The solution is based upon the general small-deflection theory for flat sandwich plates developed in NACA Rep. 899.

NACA TN 2639

FATIGUE STRENGTHS OF AIRCRAFT MATERIALS. AXIAL-LOAD FATIGUE TESTS ON NOTCHED SHEET SPECIMENS OF 24S-T3 AND 75S-T6 ALUMINUM ALLOYS AND OF SAE 4130 STEEL WITH STRESS-CONCENTRATION FACTOR OF 1.5. H. J. Grover, W. S. Hyler and L. R. Jackson, Battelle Memorial Institute. February 1952. 22p. diagrs., 9 tabs. (NACA TN 2639)

Results are given of axial-load fatigue tests on notched specimens of 24S-T3 and 75S-T6 aluminum alloys and of normalized SAE 4130 steel. Each specimen was notched by edge notches designed to have a theoretical stress-concentration factor of 1.5. Tests were run at nominal mean stresses of 0, 10,000, 20,000, and 30,000 psi. Results extend previously reported data on unnotched specimens and specimens more severly notched afford data on the variation of fatigue strength reduction with notch severity.

NACA TN 2642

APPLICATION OF LINEAR ANALYSIS TO AN EXPERIMENTAL INVESTIGATION OF A TURBOJET ENGINE WITH PROPORTIONAL SPEED CONTROL. Marcel Dandois and David Novik. February 1952. 38p. diagrs., photos. (NACA TN 2642)

Results of analytical and experimental investigations of a turbojet engine with proportional speed control are compared. Linear analysis and description of the engine as a first-order linear system were found adequate for analytical prediction of the response and stability of the controlled engine. Characteristics of proportional speed control determined from the effect of loop gain on response, speed error, and stability are presented.

NACA TN 2646

INVISCID FLOW ABOUT AIRFOILS AT HIGH SUPERSONIC SPEEDS. A. J. Eggers, Jr. and Clarence A. Syvertson. March 1952. 65p. diagrs., tab. (NACA TN 2646)

The flow about curved airfoils is investigated analytically at high supersonic speeds assuming air behaves first as an ideal, and then as a calorically imperfect gas. For ideal gas flows it is shown that the shock-expansion method accurately predicts pressure distributions on curved airfoils at arbitrarily high Mach numbers provided the flow deflection angles are not too close to those corresponding to shock detachment. Forms of the shock-expansion method and the method of characteristics, generalized to consider the caloric imperfections of air and applicable for local air temperatures up to 5000° R are obtained and investigated. This shock-expansion method also exhibits a wide range of applicability and is shown to be useful in calculating the entire flow field about an airfoil. High Mach number approximations to both shock-expansion methods are investigated and presented in forms suitable for application to engineering problems.

NACA TN 2654

TWO-DIMENSIONAL FLOW ON GENERAL SURFACES OF REVOLUTION IN TURBOMACHINES. John D. Stanitz and Gaylord O. Ellis. March 1952. 44p. diagrs., tab. (NACA TN 2654)

A method of analysis is developed for two dimensional flow on general surfaces of revolution in turbomachines with arbitrary blade shapes. The method of analysis is developed for steady, compressible, nonviscous, irrotational flow that is assumed uniform normal to the surfaces of revolution. Incompressible solutions on a mean surface of revolution between the hub and shroud are presented for four flow rates through each of two centrifugal impellers with the same hub-shroud contours but with different blade spacings. In addition, correlation equations are developed whereby the velocity components and the stream function distribution can be predicted for compressible or incompressible flow in straight-bladed impellers only, with any tip speed, flow rate, area variation, blade spacing, and for any flow surface of revolution.

NACA RM E51L17

A PHOTOGRAPHIC STUDY OF FREEZING OF WATER DROPLETS FALLING FREELY IN AIR. Robert G. Dorsch and Joseph Levine. February 1952. 29p. diagrs., photos., 2 tabs. (NACA RM E51L17)

The freezing of free-falling water droplets in air was investigated by a photographic technique. Information on the following was obtained: (1) droplet shape after freezing, (2) the occurrence of collisions of partly frozen or frozen and liquid droplets, and (3) the freezing temperatures of individual free-falling droplets.

NACA RM E51L18

AN ACTIVE PARTICLE DIFFUSION THEORY OF FLAME QUENCHING FOR LAMINAR FLAMES. Dorothy M. Simon and Frank E. Belles. March 1952. 24p. diagrs., 3 tabs. (NACA RM E51L18)

An equation for quenching distance based on the destruction of chain carriers by the surface is derived. The equation expresses the quenching distance in terms of the diffusion coefficients and partial pressures of the chain carriers, the time between effective collisions of chain carriers and gas phase molecules, the efficiency of the surface as a chain

breaker, the total pressure of the mixture, and a constant which depends on the geometry of the quenching surface. Quenching distances measured by flashback for propane-air flames are shown to be consistent with the mechanism. The derived equation is used with the lean inflammability limit and a rate constant calculated from burning velocity data to estimate quenching distances for propane-air (hydrocarbon lean) flames satisfactorily.

NACA RM E51L20

FRICTION AND SURFACE DAMAGE OF SEVERAL CORROSION-RESISTANT MATERIALS. Marshall B. Peterson and Robert L. Johnson. February 1952. 20p. photos., diagrs., 2 tabs. (NACA RM E51L20)

Friction and surface damage of several materials that are resistant to corrosion due to liquid metals was studied in air. The values of kinetic friction coefficient at low sliding velocities and photomicrographs of surface damage were obtained. Appreciable surface damage was evident for all materials tested. The friction coefficients for the combinations of steel, stainless steel, and monel sliding against steel, stainless steel, nickel, Inconel, and Nichrome ranged from 0.55 for the monel-Inconel combination to 0.97 for the stainless-steel-nickel combination; for steel, stainless steel, monel, and tungsten carbide against zirconium, the friction coefficient was approximately 0.47. Lower coefficients of friction (0.20 to 0.60) and negligible surface failure at light loads were obtained with tungsten carbide when used in combination with various plate materials.

NACA RM E52A08

VARIATION OF PRESSURE LIMITS OF FLAME PROPAGATION WITH TUBE DIAMETER FOR VARIOUS ISOOCTANE-OXYGEN-NITROGEN MIXTURES. Adolph E. Spakowski and Frank E. Belles. March 1952. 20p. diagrs. (NACA RM E52A08)

An investigation was made of the change in the pressure limits of flame propagation with tube diameter for various isooctane-oxygen-nitrogen mixtures. Pressure limits were measured in cylindrical glass tubes of four different inside diameters at six different oxygen-nitrogen ratios. Under the experimental conditions, flame propagation was found to be impossible in isooctane-oxygen-nitrogen mixtures with oxygen concentrations less than 11 to 12 percent. Critical tube diameters for flame propagation were calculated and the effect of pressure was determined and compared with the effect of pressure on quenching distance. Critical diameters were related to flame speeds for various isooctane-oxygen-nitrogen mixtures.

NACA TM 1333

ON ROTATIONAL CONICAL FLOW. (Sui Moti Conici Rotazionali). Carlo Ferrari. February 1952. 12p. diagrs. (NACA TM 1333. Trans. from Onore di Modesto Panetti, November 25, 1950).

Some general properties of isoenergetic rotational conical fields are determined. For such fields, provided the physical parameters of the fluid flow are known on a conical reference surface, it being understood that they satisfy certain imposed conditions, it is shown how to construct the hodographs in the various meridional semiplanes, as the envelope of either the tangents to the hodographs or of the osculatory circles.

NACA TM 1329

CONCERNING THE FLOW ABOUT RING-SHAPED COWLINGS. PART IX - THE INFLUENCE OF OBLIQUE ONCOMING FLOW ON THE INCREMENTAL VELOCITIES AND AIR FORCES AT THE FRONT PART OF CIRCULAR COWLS. (Über die Strömung an ringförmigen Verkleidungen. IX Mitteilung: Der Einfluss der Schräganblasung auf die Uebergeschwindigkeiten und Luftkräfte am vorderen Teil von Ringhauben). Dietrich Küchemann and Johanna Weber. February 1952. 16p. diagrs. (NACA TM 1329) Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1236/9; Aerodynamische Versuchsanstalt Göttingen E. V. Institut für theoretische Aerodynamik. (Bericht) 43/A/10. June 10, 1943).

The dependence of the maximum incremental velocities and air forces on a circular cowling on the mass flow and the angle of attack of the oblique flow is determined with the aid of pressure-distribution measurements. The particular cowling tested had been partially investigated in NACA TM 1327.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF THE CONDENSATION OF ATMOSPHERIC WATER VAPOUR ON TOTAL HEAD AND OTHER MEASUREMENTS IN THE N.P.L. HIGH SPEED TUNNELS. H. H. Pearcey. NOTE ON THE INTERPRETATION OF READINGS OF PITOT AND STATIC TUBES IN A HIGH SPEED TUNNEL IN WHICH CONDENSATION OF MOISTURE IS TAKING PLACE. C. N. H. Lock. 1951. 38p. diagrs., 5 tabs. (ARC R & M 2249. Formerly ARC 7482; FM 669; 8455; FM 776)

At high Mach numbers condensation causes a considerable total-head loss which increases with distance along the working section, and serious discrepancies in pitot traverse drag which most probably increase with airfoil chord. It is considered that future high-speed tunnels, especially if they are built with longer working sections or to take larger chord airfoils, should be so constructed as to permit the use of dry air.

PARACHUTE DESIGN. T. F. Johns. 1951. 30p. diagrs., 4 tabs. (ARC R & M 2402; ARC 10,579. Formerly RAE Tech. Note Arm. 365)

This report records the methods of parachute design which have been developed in England during the latter part of the war. It begins with a discussion of the main characteristics of a parachute and of the effects of various factors on these characteristics. It then describes the main types of parachute which are at present in use and discusses the merits of each type. Details are given of the methods of manufacture which have been found to be the most satisfactory.

EXPRESSIONS FOR THE RATES OF CHANGE OF CRITICAL FLUTTER SPEEDS AND FREQUENCIES WITH INERTIAL, AERODYNAMIC AND ELASTIC COEFFICIENTS. G. H. L. Buxton and I. T. Minhinnick. 1951. 71p. diagrs. (ARC R & M 2444; ARC 9140. Formerly RAE SME 3339)

Formulas are derived giving the rates of change of the critical speeds and frequencies for flutter of an aeroelastic system of a general number of degress of freedom, with each of the dynamical coefficients occurring in the equations of motion. Summation relations between the rates of change are obtained. Special forms of formulas for binary flutter are given and simple formulas for rates of change of critical speeds and frequencies when all the coefficients of a given type are changed in the same ratio are obtained for this particular case.

Aeronautical Research Council (Gt. Brit.)
LOW-SPEED WIND-TUNNEL TESTS ON THE BAYNES CARRIER WING; A TAILLESS GLIDER. J. Trouncer. 1951. 41p. diagrs., 35 tabs. (ARC R & M 2487; ARC 6608; ARC 7125; ARC 7127; ARC 8590; ARC 8910. Formerly RAE Aero 1802; Tech. Note Aero 1191; Tech. Note Aero 1608; Tech. Note Aero 1672)

Longitudinal and lateral stability tests were made on the glider as designed with a tank and with a fuselage replacing the tank. The effects of end fins, split flaps, and elevons are also given. In the final design condition with the fuselage instead of the tank the maximum trim lift coefficient was 1.08 (flaps up) and 1.27 (flaps down). Instability developed before the stall, flaps up, but could be cured by fitting tip slats. The changeover from tank to fuselage caused a decrease in C_{m_o} of 0.019; of this change ΔC_{m_o} tank = +0.001 and ΔC_{m_o} fuselage = -0.020.

MEASUREMENT OF AIRCRAFT ATTITUDE RELATIVE TO FLIGHT PATH DURING DIVES. J. E. H. Braybon. 1951. 11p. diagrs., photos. (ARC R & M 2564; ARC 10,604. Formerly AAEE Rept. A.A.E.E./Arm/Res/13)

Deals with development of a technique for direct recording of the attitude of an aircraft relative to flight path during dives, that is, the direction of incidence of free air flow relative to aircraft datum, using a wind vane coupled to a Desynn transmitter. Results obtained under steady conditions of dive angle and A.S.I. show agreement with those deduced from level flight results using conventional air-flow incidence/lift-coefficient relation. Included are details of instrumentation required to obtain simultaneous records of flight conditions and corresponding incidence under nonsteady conditions such as exist during rocketry attacks.

Aeronautical Research Council (Gt. Brit.)
A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE FLOW IN A DUCT OF VARYING CROSS-SECTION, WITH PARTICULAR APPLICATION TO THE DESIGN OF DUCTS FOR FREE FLIGHT GROUND-LAUNCHED MODEL TESTS. C. H. E. Warren, R. E. Dudley and P. J. Herbert. 1951. 37p. diagrs., 4 tabs. (ARC CP 60; ARC 13,726)

The flow in a duct was investigated theoretically for the case when there are no internal shocks or separation, and the results have been confirmed by wind-tunnel tests. The theoretical results are used to predict the flow where there are no internal shocks or separation in the duct. The wind-tunnel results are required to determine the flow when separation occurs. In such cases, it is found that the jumps in static pressure in the region of the breakaway are in fair agreement with the jumps found by Eggink in experiments of a related nature. It does not appear possible to predict the position of the regions of breakaway from the few tests made. It is considered that at supersonic free-stream Mach numbers the internal drag can be calculated with fair accuracy, but that at subsonic Mach numbers an appreciable uncertainty may be caused by an error in the estimation of the static pressure on the base of the duct.

Aeronautical Research Council (Gt. Brit.)
OBSERVATIONS OF THE SUPERSONIC FLOW ROUND A 6% THICK DOUBLE WEDGE. D. W. Holder, A. Chinneck and D. G. Hurley. December 28, 1950. 12p. photos., diagrs., tab. (ARC CP 63; ARC 13,623)

At a Mach number of 1.57 and Reynolds number of 0.8×10^6 pressure measurements and flow photographs were taken for a 6 percent thick two-dimensional symmetrical double wedge at angles of attack between 0° and 8°. Although the results are in general agreement with exact theory, discrepancies occur at mid-chord where the expansion is observed to be more gradual than would be expected in the absence of boundary layer, and close to the trailing edge where separation occurs when the airfoil is at angle of attack. Shock waves were observed at the nose and tail under conditions for which expansions alone would be expected.

TESTS ON A 'LIGHTHILL' NOSE-SUCTION AEROFOIL IN THE N.P.L. 4-FT. NO. 2 WIND TUNNEL. F. Cheers, W. G. Raymer and Ola Douglas. 1951. 7p. diagrs., photos. (ARC R & M 2355. Formerly ARC, Performance Sub-Committee 10,506; Perf.301; FM 1095)

A series of tests on an 8.6 percent thick nose-suction airfoil designed by Lighthill has been made in the 4-ft No. 2 wind tunnel at the National Physical Laboratory at Reynolds numbers of 0.385 and 0.577×10^6. The results show that the wing stalls at $\alpha \leq 13^\circ (C_L = 1.12)$ without suction, the lift coefficient at the stall increasing approximately linearly with suction quantity and reaching 1.93 at $C_Q = 0.019$ and 23° angle of attack.

TESTS ON YAWED AEROFOILS IN THE 20 x 8-IN. HIGH SPEED TUNNEL. J. A. Beavan and N. Bumstead. 1951. 9p. diagrs. (ARC R & M 2458. Formerly ARC, Fluid Motion Sub-Committee 10,730; FM 1133)

Tests on NACA 0020 sections of 1.2 and 2.0-inch chord completely spanning the tunnel, yawed 40° and straight, showed that there was no appreciable difference in compressibility drag rise due to wind-tunnel interference. The results, and further measurements on a Piercy airfoil previously tested, showed also that the gain in Mach number has been increased from 65 to about 80 percent of the theoretical value that assumes infinite span and no boundary layer effects due to reduction of tunnel humidity. Some explorations of the flow behind the airfoil are considered to justify these conclusions at Mach numbers up to at least 0.92.

AN INVESTIGATION INTO THE EFFECT OF FORCED AND NATURAL AFTERBODY VENTILATION ON THE HYDRODYNAMIC CHARACTERISTICS OF A SMALL FLYING BOAT (SARO 37) WITH A 1:15 FAIRING OVER THE MAIN STEP. J. A. Hamilton. 1951. 28p. diagrs., photos., 2 tabs. (ARC R & M 2463; ARC 10,589. Formerly MAEE Rept. F/Res/204)

The fairing with no ventilation reduced the steady-run stability range to 3°, produced violent skipping in steady runs and landings, reduced the stable range of attitudes for landing, elevator fixed, to 2°, and so increased the water resistance beyond the hump that take-off within a certain range of attitudes was impossible without considerable pitching disturbance. Natural ventilation increased the steady-run stability range, reduced the violence of skipping in steady runs and landings, increased the stable range for landing, elevator fixed, to 4°, reduced water resistance so that only mild afterbody sticking occurred, and reduced the free-to-trim attitudes in the planing range by 2°. The addition of forced ventilation to natural ventilation raised the skipping limit in steady runs approximately 1°, and eliminated afterbody sticking.

A METHOD OF DESIGNING CORNER CHANNELS AND CASCADES ON A HYPERBOLIC BASE-LINE. R. J. Monaghan. 1951. 10p. diagrs., tab. (ARC R & M 2464; ARC 9522. Formerly RAE Aero 2104)

Presents a method for the design of two-dimensional corner channels and cascade airfoils. The first step is to construct a flow pattern which satisfies the given flow conditions. Any two streamlines are then chosen as the boundaries of a corner channel, and a number of similar channels are placed side by side with their outer streamlines coinciding at infinity in each direction. If the velocity distributions in the channels are suitable a closed airfoil section is left between each pair. It only remains to round off the leading edge to allow for slight changes in angle of attack, and the cascade airfoil is obtained.

SOME OBSERVATIONS ON SHARP-NOSED PROFILES AT SUPERSONIC SPEED. J. Valensi and F. W. Pruden. (Presented to VI International Congress of Applied Mechanics). 1951. 17p. photos., diagrs. (ARC R & M 2482. Formerly ARC, Fluid Motion Sub-Committee 10,607; FM 1108)

Two-dimensional tests have been made on two airfoils, one a wedge section and the other a double wedge section, each with a nose semiangle of 3.6^{0}. The tests were made in a 5- by 2-inch wind tunnel at M = 1.4, and comprised Schlieren observation and pressure measurement. The results have been compared with exact inviscid theory. Several divergences were noticed and are discussed. Excellent agreement with theory was obtained under certain conditions, and where serious disagreement occurred it was partly attributable to wind tunnel interference.

PREVENTION OF CASTOR SHIMMY BY THE TWIN-CONTACT TYPE. O. J. Marstand. 1951. 15p. diagrs., photo. (ARC R & M 2508. Formerly RAE SME 3195)

Results of full-scale experiments on shimmy suppression by the twin-contact pneumatic tire are given. These results are supported theoretically and by some related facts of experience. The method is compared with existing ones and some practical considerations are discussed. The method is generally effective in tail and nose wheels without the use of other forms of heavy damping, over which it may have some advantages in simplicity, cost and effectiveness. It is likely to be suitable for production and use in new aircraft and some existing types.

THE IDEAL DRAG DUE TO A SHOCK WAVE. C. N. H. Lock. 1951. 17p. diagrs., 4 tabs. (ARC R & M 2512. Formerly ARC, Aerodynamics Sub-Committee 5852; FM 528; Ae. 2032; ARC, Fluid Motion Panel 8458; FM 777)

The subject of this note is the increase of the drag of an airfoil which arises from the presence of limited shock waves when the forward speed lies between the so-called shock stalling speed and the velocity of sound. Part 1 presents a method of calculating a first approximation to the ideal theoretical drag rise due to a shock wave on an airfoil. Part 2 extends the method to cover the use of the Kármán-Tsien solution in place of the Glauert relation.

AN APPROXIMATE SOLUTION OF TWO FLAT PLATE BOUNDARY-LAYER PROBLEMS. E. J. Watson and J. H. Preston. 1951. 13p. diagrs., 3 tabs. (ARC R & M 2537. Formerly ARC, Fluid Motion Sub-Committee 9914; FM 982)

The method presented here for obtaining an approximate solution of the laminar boundary-layer equations is based on the iteration process of Piercy and Preston. It leads to a simple analytical approximation of good accuracy for Blasius' solution of the boundary-layer flow past a flat plate. The main purpose of this paper is, however, the application of the method to a generalization of Blasius' problem, namely the case of a flat plate in a uniform stream when there is a suction velocity normal to the plate proportional to $x^{-1/2}$ where x is the distance along the plate from its leading edge.

A REVIEW OF THE PROBLEM OF CHOOSING A CLIMB TECHNIQUE, WITH PROPOSALS FOR A NEW CLIMB TECHNIQUE FOR HIGH PERFORMANCE AIRCRAFT. K. J. Lush. 1951. 15p. diagrs (ARC R & M 2557; ARC 11,708; ARC 12,081. Formerly AAEE Rept. A. A. E. E. /Res/237)

The problem of choosing the best climbing technique is considered and limitations of the present technique discussed. Introduction of "energy height" as a variable permits a more exact treatment to be attempted and enables a geometrical illustration to be developed of the general problem of optimum climb between specified end conditions. From discussion of this illustration it is tentatively concluded that a revised climb technique, outlined in this report, will give improved performance by building up a relatively high kinetic energy at low altitudes for conversion into potential energy (that is height) at high altitudes.

A NEW METHOD OF NUMERICAL INTEGRATION OF THE EQUATIONS OF THE LAMINAR BOUNDARY LAYER. T. G. Cowling. 1951. 14p. diagrs., 5 tabs. (ARC R & M 2575. Formerly ARC, Fluid Motion Sub-Committee 8690; FM 808)

This new method for the numerical solution of the boundary-layer equations rests on the fact that the equations of steady flow are special cases of the equations of general motion. Velocity profiles are found at successive sections across the boundary layer. Trial values of the velocity are assumed at any section. From these, space derivatives of the velocity are deduced by using finite differences, and time derivatives by using the equations of motion. Trial values are then adjusted to give zero time derivatives of the velocity at the section.

APPROXIMATE CALCULATION OF THE TURBULENT BOUNDARY LAYER IN TWO-DIMENSIONAL INCOMPRESSIBLE FLOW. E. C. Maskell. November 1951. 61p. diagrs., 2 tabs. (RAE Aero 2443)

An approximate method is constructed for calculating the development of the turbulent boundary layer, given the velocity distribution outside the layer. The characteristics which may be determined are the momentum thickness θ, the profile parameter H, the skin-friction coefficient c_f, and the separation point. By making use of an empirical approximation, the momentum equation is directly integrated to determine θ. H is determined from an empirical differential equation similar in form to the von Doenhoff-Tetervin and Garner equations. The Ludwieg-Tillman formula is used to calculate the skin friction and, by extrapolation, to determine the separation point.

STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. GENERAL INTRODUCTION AND PART I. THE DEVELOPMENT OF A COMBUSTION TEST RIG FOR MEASURING THE IGNITION DELAY OF FUELS. B. P. Mullins. August 1951. 32p. diagrs., photo., 2 tabs. (NGTE R. 89)

A standardized test rig, consisting essentially of a 6-inch-diameter metal duct through which the hot vitiated air from a slave combustion chamber is passed and into which fuel is injected, has been fully devel-

oped to measure ignition delays under appropriate conditions of short reaction time. The ignition delay is calculated from measurements of the length of the induction zone and the air velocity. The apparatus and technique are described and some theoretical aspects of the work are discussed in this report which includes some typical results for a kerosene spray.

N-13589*

National Gas Turbine Establishment (Gt. Brit.) STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART II. THE EFFECT OF PHYSICAL FACTORS UPON THE IGNITION DELAY OF KEROSINE-AIR MIXTURES. B. P. Mullins. September 1951. 56p. diagrs., 17 tabs. (NGTE R. 90)

The effect of a number of physical variables upon the ignition delay of kerosene was measured in the combustion rig described in NGTE R. 89. Air/fuel ratio and gas velocity have a negligible effect; spray particle size, fuel temperature, and coarse air turbulence have a small effect. Thus, the ignition delay at a given air temperature increases at the rate of ~1 percent per 3μ increase in spray Sauter mean diameter, decreases by ~15 percent with 60° C of fuel preheat, decreases by ~25 percent with fuel prevaporization, and is changed slightly when the induction zone is situated in the wake of a baffle plate.

CONTRIBUTIONS TO THE HOT-WIRE METHOD. (Beiträge zur Hitzdrahtmethode). G. Datwyler. January 1952. 32p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 1, no. 5, 1950, p.298-316).

The characteristics of hot wires are calculated approximately, by using the experimental results of the heat loss of thin cylinders in a cross-stream. They are based upon the similarity law of heat transfer by forced convection. The approximation lies in that the heat losses at the two ends of such probes are neglected, so that the results apply exactly only to wires of finite length as a part of infinitely long wires. Starting from an evaluation formula previously derived, a practical method is developed for determining the sensitivity of hot-wire probes. This method is based on the complete semiempirical equation by King.

DECLASSIFIED NACA REPORTS

NACA ACR L5H31*

COMPARISON OF TESTS OF A 4-FOOT-DIAMETER PROPELLER IN THE LANGLEY 8-FOOT AND 16-FOOT HIGH-SPEED TUNNELS. Morton Cooper. March 1946. 24p. diagrs., photo. (NACA ACR L5H31) (Declassified from Restricted, 2/28/52)

Tests have been conducted to compare the characteristics of a given propeller in different wind tunnels. NACA 4-(3.9)(07)-0345-C propeller characteristics are given for blade angles of 26°, 31.5°, 36.5°, 41°, and 45° at the 0.75 radius at a tunnel Mach number of 0.200 and for blade angles of 41°, 45°, and 49° at a tunnel Mach number of 0.480. Agreement for the corrected results is within 0.5 percent over most of the range tested, is well within experimental accuracy, and indicates that no tunnel-wall effects of significant magnitude exist other than those for which corrections are currently applied.

NACA ARR L6D23*

EFFECT OF SHANK DESIGN ON PROPELLER PERFORMANCE AT HIGH SPEEDS. James B. Delano and Melvin M. Carmel. June 1946. 87p. diagrs., photos., tab. (NACA ARR L6D23) (Declassified from Restricted, 2/28/52)

Tests of three two-blade propellers, designed for the the same operating condition and differing essentially only in shank design have been made through a range of blade angle from 20° to 58.5° for free-stream Mach numbers ranging from 0.20 to 0.70. The propellers have thickness ratios of 0.185, 0.500, and 1.000 at the spinner surface. The results indicate that the losses due to compressibility effects on the outboard sections can be minimized by the use of thin shank sections capable of carrying a large part of the thrust load.

NACA RM L6L20a

SUMMARY OF AVAILABLE DATA RELATING TO REYNOLDS NUMBER EFFECTS ON THE MAXIMUM LIFT COEFFICIENTS OF SWEPT-BACK WINGS. Harold H. Sweberg and Roy H. Lange. March 4, 1947. 20p. diagrs., tab. (NACA RM L6L20a) (Declassified from Restricted, 2/28/52)

The foreign and American data show that a low Reynolds numbers (below about 2×10^6) higher maximum lift coefficients were measured in most cases for moderately sweptback wings than for unswept wings of similar plan form; at high Reynolds numbers, however, increasing sweepback resulted in decreasing maximum lift coefficients. A smaller rate of increase of the maximum lift coefficient with Reynolds number was measured for the sweptback wings than for similar unswept wings in the critical range of Reynolds number. Increasing the Reynolds number resulted in decreases in the maximum lift coefficients of the two wings of approximately triangular plan form that were investigated.

NACA RM L6L27a

AERODYNAMIC CHARACTERISTICS AT HIGH SPEEDS OF FULL-SCALE PROPELLERS HAVING DIFFERENT SHANK DESIGNS. Julian D. Maynard. February 13, 1947. 72p. diagrs., photos., tab. (NACA RM L6L27a) (Declassified from Restricted, 2/28/52)

Tests of two two-blade propellers differing essentially in shank design only have been made. One propeller had a shank section typical of conventional blades and the other had an aerodynamically efficient airfoil section. The blades were tested through a range of angles from 20° to 55° at various rotational speeds and at airspeeds up to 496 mph. Although both propellers were very efficient, the one with the efficient airfoil section was about 5 percent more efficient.

NACA RM L7K28

HIGH-SPEED WIND-TUNNEL INVESTIGATION OF A FLYING-BOAT HULL WITH HIGH LENGTH-BEAM RATIO. John M. Riebe and Rodger L. Naeseth. June 20, 1948. 30p. diagrs., photo., 4 tabs. (NACA RM L7K28) (Declassified from Restricted, 2/28/52)

An investigation was made in the Langley high-speed 7- by 10-foot tunnel of a high length-beam ratio flying boat hull, the hull with step fairing, the hull with bottom rounded, and for comparison a streamline body of revolution. Mach numbers ranged from 0.4 to 0.85; angles of attack ranged from -2° to 7.25° at the low Mach numbers. Drag coefficients and longitudinal and lateral-stability parameters presented include the interference of the thin 40° sweptback support wing.

NACA RM L50H17a

A METHOD FOR PREDICTING THE LOW-SPEED CHORDWISE PRESSURE DISTRIBUTION OVER SHARP-EDGE AIRFOIL SECTIONS WITH PLAIN FLAPS AT THE LEADING AND TRAILING EDGES. Robert J. Nuber and Jones F. Cahill. October 2, 1950. 28p. diagrs. (NACA RM L50H17a) (Declassified from Restricted, 2/28/52)

A method is presented for the calculation of the low-speed chordwise pressure distribution over various relatively thin sharp-edge airfoils equipped with leading-edge and trailing-edge flaps of arbitrary size and deflection.

CURRENT NACA REPORTS

NACA Rept. 1008

A SMALL-DEFLECTION THEORY FOR CURVED SANDWICH PLATES. Manuel Stein and J. Mayers. 1951. ii, 6p. diagrs. (NACA Rept. 1008. Formerly NACA TN 2017)

A small-deflection theory that takes into account deformations due to transverse shear is presented for the elastic-behavior analysis of orthotropic plates of constant cylindrical curvature, with consideration of buckling included. The theory is applicable primarily to sandwich construction.

NACA Rept. 1019

RELATION BETWEEN INFLAMMABLES AND IGNITION SOURCES IN AIRCRAFT ENVIRONMENTS. Wilfred E. Scull. 1951. iii, 38p. diagrs., 6 tabs. (NACA Rept. 1019. Formerly NACA TN 2227)

Data, which are applicable to the problem of aircraft fire hazards, were obtained from a literature survey and analyzed and discussed. Data pertaining to the ignition characteristics of inflammables ignited under various experimental conditions by heated surfaces, electric sparks and arcs and flames or hot gases are presented. Possible remedial measures, indicated by the survey to be capable of reducing aircraft fire hazards, are discussed.

NACA Rept. 1020

MEASUREMENTS OF AVERAGE HEAT-TRANSFER AND FRICTION COEFFICIENTS FOR SUBSONIC FLOW OF AIR IN SMOOTH TUBES AT HIGH SURFACE AND FLUID TEMPERATURES. Leroy V. Humble, Warren H. Lowdermilk and Leland G. Desmon. 1951. ii, 15p. diagrs. (NACA Rept. 1020. Formerly RM E7L31; RM E8L03; RM E50E23; RM E50H23)

An investigation of forced-convection heat transfer and associated pressure drops was conducted with air flowing through smooth tubes for an over-all range of surface temperature from 535° to 3050° R, inlet-air temperature from 535° to 1500° R, Reynolds number up to 500,000, exit Mach number up to 1, heat flux up to 150,000 Btu per hour per square foot, length-diameter ratio from 30 to 120, and three entrance configurations. Most of the data are for heat addition to the air; a few results are included for cooling of the air. The over-all range of surface-to-air temperature ratio was from 0.46 to 3.5.

NACA TN 2612

STRESS PROBLEMS IN PRESSURIZED CABINS. W. Flügge, Stanford University. February 1952. 91p. diagrs. (NACA TN 2612)

The report presents information on the stress problems in the analysis of pressurized cabins of high-altitude aircraft not met with in other fields of stress analysis relating to aircraft. The material may be roughly divided into shell problems and plate problems, the former being concerned with the curved walls of the cabin or pressure vessel and the latter being concerned with small rectangular panels of its walls, framed by stiffeners, but not necessarily plane.

NACA TN 2613

DETERMINATION OF INDICIAL LIFT AND MOMENT OF A TWO-DIMENSIONAL PITCHING AIRFOIL AT SUBSONIC MACH NUMBERS FROM OSCILLATORY COEFFICIENTS WITH NUMERICAL CALCULATIONS FOR A MACH NUMBER OF 0.7. Bernard Mazelsky. February 1952. 30p. diagrs., tab. (NACA TN 2613)

The indicial lift and moment functions for a pitching airfoil are calculated for a Mach number of 0.7 from the available flutter coefficients for an oscillating airfoil. Comparison of the indicial lift functions at a Mach number of 0 and 0.7 indicates that the growth of lift to the steady state is less rapid for compressible flow than for incompressible flow.

NACA TN 2614

ANALYTICAL INVESTIGATION ON SOME THREE-DIMENSIONAL FLOW PROBLEMS IN TURBOMACHINES. Frank E. Marble and Irving Michelson, California Institute of Technology. March 1952. 109p. diagrs., 2 tabs. (NACA TN 2614)

The flow of an incompressible inviscid fluid through a turbomachine with blade rows consisting of an infinite number of similar infinitely thin blades has been investigated theoretically in order to examine and describe the three-dimensional flow phenomena and to illustrate the methods of calculation developed.

NACA TN 2623

COMPARISON OF SUPERSONIC MINIMUM-DRAG AIRFOILS DETERMINED BY LINEAR AND NONLINEAR THEORY. E. B. Klunker and Keith C. Harder. February 1952. 19p. diagrs. (NACA TN 2623)

Supersonic profiles of minimum pressure drag for a given thickness ratio and for a given area have been determined with the use of a nonlinear pressure relation and compared with minimum-drag profiles found by linearized theory. The results show that linearized theory is adequate for determining the profile shape, though not the drag, for Mach numbers from 2 to 10 for optimum airfoils with a finite trailing-edge thickness.

NACA TN 2624

FLAME SPEEDS OF METHANE-AIR, PROPANE-AIR, AND ETHYLENE-AIR MIXUTRES AT LOW INITIAL TEMPERATURES. Gordon L. Dugger and Sheldon Heimel. February 1952. 25p. diagrs., tab. (NACA TN 2624)

Flame speeds were determined for methane-air, propane-air, and ethylene-air mixtures at -73° C and for methane-air mixtures at -132° C. The data extend the curves of maximum flame speed against initial mixture temperature previously established for the range from room temperature to 344° C. Both a thermal and diffusion theory predicted the effect of low initial temperatures within approximately 20 percent, as was found previously for high initial temperatures. The low-temperature data also extended the linear correlations between maximum flame speed and calculated equilibrium active-radical concentrations, which were established by the reported high-temperature data. Flame speed was determined from the total area of the outside edge of the shadow of a nozzle flame.

NACA TN 2625

SUMMARY OF ACCELERATION AND AIRSPEED DATA FROM COMMERCIAL TRANSPORT AIRPLANES DURING THE PERIOD FROM 1933 TO 1945. Walter G. Walker and Roy Steiner. February 1952. 30p. diagrs., 5 tabs. (NACA TN 2625)

Normal acceleration and airspeed data collected in transport airplanes from 1933 to 1945 are summarized and analyzed with respect to gusts and gust loads. The accelerations experienced in most operations equaled or exceeded the limit-gust-load-factor increment, on the average, twice (once positive and once negative) in 10^7 flight miles. The gusts experienced in most operations exceeded 33 feet per second, on the average, twice (once positive and once negative) in 10^7 flight miles. The loads experienced for several operations varied appreciably from average conditions. A predominating factor causing the variations in the load experience was the differences in the gust experience, with operating speeds in rough air being a secondary contributing or moderating factor.

NACA TN 2632

CORROSION OF MAGNESIUM ALLOY ZK60A IN MARINE ATMOSPHERE AND TIDEWATER. Fred M. Reinhart, National Bureau of Standards. February 1952. 10p. photos., 4 tabs. (NACA TN 2632)

The corrosion resistance of unprotected magnesium-zinc-zirconium alloy ZK60A was determined in a marine atmosphere and in tidewater. The unprotected alloy was so rapidly attacked in tidewater that it would be of no practical value in applications subject to wetting by sea water. In the marine atmosphere, the rate of corrosion was much less and the alloy should give good service if adequately protected.

NACA TN 2638

STUDY OF INADVERTENT SPEED INCREASES IN TRANSPORT OPERATION. Henry A. Pearson. March 1952. 29p. diagrs., tab. (NACA TN 2638)

Some factors relating to the speed and Mach number margins required in operation of transport airplanes are discussed for the purpose of indicating how these margins should vary with the airplane qualities. Most of the cases investigated show that on a percentage basis smaller margins should be required of the faster airplane than the slower airplane. Equations are suggested which allow these margins to be estimated.

NACA TN 2645

EFFECTS OF WING LIFT AND WEIGHT ON LANDING-GEAR LOADS. Dean C. Lindquist. March 1952. 42p. diagrs., photo., tab. (NACA TN 2645)

The effects of wing lift and weight on maximum landing gear loads were investigated by drop testing a small landing gear with an oleo shock strut in the Langley impact basin. Lift forces were mechanically applied to the dropping mass to produce wing lift factors between 0 and 2. 0. Dropping weight ranged between 1000 and 2500 pounds. The results show the relationship between lift force, weight, and landing-gear loads for a range of vertical velocities between 0 and 12 feet per second.

NACA TN 2647

IMPLICATION OF THE TRANSPORT EQUATION FOR THE SEMIEMPIRICAL TREATMENT OF SHIELDS. Philip Schwed. March 1952. 31p. (NACA TN 2647)

The semiempirical method of dealing with shields by treating them as composed of layers is revised and extended by taking the angular distribution of the radiation into account and by making use of the trans-

port equation to obtain expansions suitable for special cases. Such expansions are given for the case where multiple scattering with angular deviation is of relatively little import and for the contrary case where this latter process dominates. A method for obtaining the parameters for layers of finite thickness from data on very thin layers is presented. The expansion used for the case where multiple scattering dominates is illustrated by consideration of a thick nonabsorbing neutron shield of high atomic weight. The physical significance of the expansion coefficients introduced is determined.

NACA TN 2648

EXPERIMENTAL INVESTIGATION OF TRANSITION OF A MODEL HELICOPTER ROTOR FROM HOVERING TO VERTICAL AUTOROTATION. S. E. Slaymaker, Robert R. Lynn and Robin B. Gray, Princeton University. March 1952. 29p. diagrs., photos. (NACA TN 2648)

An experimental investigation was made of the variation of average induced flow around a model helicopter during transition from hovering flight to steady autorotative vertical descent. Test data were obtained from simulated power failures under many different conditions. Results are summarized for variation in disk loading, blade angles, and pitch-change rate and "effective induced velocities" calculated for the various conditions are presented. Comparisons of theoretical and experimental data indicate that conditions peculiar to vertical descent in the transition range cause variations in performance not predicted by the theoretical analysis.

NACA TN 2649

EFFECT OF MACH NUMBER ON THE FLOW AND APPLICATION OF COMPRESSIBILITY CORRECTIONS IN A TWO-DIMENSIONAL SUBSONIC-TRANSONIC COMPRESSOR CASCADE HAVING VARIED POROUS-WALL SUCTION AT THE BLADE TIPS. William B. Briggs. March 1952. 43p. diagrs., photos. (NACA TN 2649)

A 65-(12)10 compressor blade cascade was evaluated at design geometry for Mach numbers from 0.12 to 0.89 with the boundary layer controlled through upstream slots and porous walls. The suction control was specified by a two-dimensionality criterion. The data show the effect of Mach number on turning angle, blade wake, blade profile pressure distribution, and static-pressure rise. The influence of suction on these parameters and secondary losses is illustrated. A system for correlating the experimental static-pressure rise with the theoretical is presented. Prandtl-Glauert and Kármán-Tsien compressibility correction predictions are compared with the data. A new method utilizing the vector-mean velocity and the contraction coefficient is presented.

NACA TN 2650

RADIOAUTOGRAPHIC METHOD FOR EXAMINING DISTRIBUTION OF PARTICLES IN A CYCLOTRON BEAM. M. L. Pool and S. Fultz, Ohio State University Research Foundation. March 1952. 20p. diagrs., photos., 5 tabs. (NACA TN 2650)

The relative distribution of particles emitted from activated metal foil has been obtained by the use of radioautographs of the foil, and hence the time-averaged distribution of particles in the cyclotron beam which causes activation of the foil can also be obtained. This has been established for Kodak Super Pan Press B film provided the maximum photographic density of the radioautograph is kept below 1.1. The method has been confirmed by direct comparison of density values and count rates and has also been verified for higher energy components of the β-rays emitted from the foils.

NACA TN 2651

SUPERSONIC CONICAL FLOW. Stephen H. Maslen, Brown University. March 1952. 32p. diagrs., tab. (NACA TN 2651)

A numerical method is described for the solution of the nonlinear equations for supersonic conical flow. The procedure is a combination of the method of characteristics and the relaxation process. A method for calculating the position of the shock is inherent in the analysis. The method presented is applicable to any conical flow and a solution for the flow about a triangular wing with supersonic leading edges is included as an illustration.

NACA TN 2652

APPLICATION OF A CHANNEL DESIGN METHOD TO HIGH-SOLIDITY CASCADES AND TESTS OF AN IMPULSE CASCADE WITH 90° OF TURNING. John D. Stanitz and Leonard J. Sheldrake. March 1952. 65p. diagrs., photos., 2 tabs. (NACA TN 2652)

A technique is developed for the application of a channel design method to the design of high-solidity cascades with prescribed velocity distributions as a function of arc length along the blade-element profile. The technique applies to both incompressible and subsonic linearized compressible (ratio of specific heats equal to -1.0), nonviscous, irrotational, fluid motion. An impulse cascade with 90° turning was designed for incompressible flow and was tested at the design angle of attack over a range of downstream Mach number from 0.2 to choke flow. To achieve good efficiency, the cascade was designed for prescribed velocities with maximum allowable blade loading according to limitations imposed by considerations of boundary-layer separation.

NACA TN 2653

A THERMODYNAMIC STUDY OF THE TURBINE-PROPELLER ENGINE. Benjamin Pinkel and Irving M. Karp. March 1952. 90p. diagrs. (NACA TN 2653)

Equations and charts are presented for computing performance parameters of a turbine-propeller engine for any given set of operating conditions and component efficiencies. In order to illustrate some of the turbine-propeller system performance characteristics, the total thrust horsepower per unit mass rate of air flow and the specific fuel consumption are presented for a wide range of flight engine design operating conditions and given design component efficiencies. The performance of a turbine-propeller engine containing a matched set of components is presented for a range of engine operating conditions. The influence of the characteristics of the individual components of off-design-point performance is shown. The flexibility of operation of two turbine-propeller engines is discussed; one engine has a divided turbine system in which the first turbine drives only the compressor and the second turbine independently drives the propeller, and the other engine has a connected turbine system which drives both the compressor and the propeller.

NACA TN 2655

CRITICAL STUDY OF INTEGRAL METHODS IN COMPRESSIBLE LAMINAR BOUNDARY LAYERS. Paul A. Libby, Morris Morduchow and Martin Bloom, Polytechnic Institute of Brooklyn. March 1952. 40p. diagrs., 3 tabs. (NACA TN 2655)

A number of the most promising integral methods for solving approximately the compressible-laminar-boundary-layer equations are investigated in order to determine a convenient and accurate method of calculating boundary-layer characteristics. The chief methods considered are the one-parameter Kármán-Pohlhausen method with three different assumptions for the velocity profiles and the two-parameter method with two different assumptions for the velocity profiles. Comparison of the results is made with those of known exact solutions for skin-friction and heat-transfer coefficients, velocity profiles, velocity derivatives, and especially laminar-boundary-layer stability. From this comparison, it is found that Kármán-Pohlhausen method with the sixth-degree polynomial as the velocity profile is the most suitable for many practical purposes.

NACA TN 2658

LAMINAR BOUNDARY LAYER OVER FLAT PLATE IN A FLOW HAVING CIRCULAR STREAMLINES. Artur Mager and Arthur G. Hansen. March 1952. 28p. diagrs., tab. (NACA TN 2658)

The laminar-boundary-layer development over a semi-infinite flat plate placed in a flow with concentric circular streamlines was investigated with the limitation of small total turning of the main-stream flow. The shape of the velocity profiles in the direction of the main-stream flow and perpendicular to it was analytically determined for an incompressible flow and a compressible flow with Prandtl number equal to 1. The boundary-layer thickness was shown to be proportional to the square root of the distance from the leading edge of the plate when measured along the streamline of the main-stream flow. The deflection of the boundary-layer flow at the plate surface from the direction of a circular streamline in the main flow was shown to vary directly with the turning. With increase in the Mach number of the main-stream flow, both the boundary-layer thickness and the deflection increased.

NACA TN 2664

EXPERIMENTAL INVESTIGATION OF THE TURBULENT-BOUNDARY-LAYER TEMPERATURE-RECOVERY FACTOR ON BODIES OF REVOLUTION AT MACH NUMBERS FROM 2.0 TO 3.8. Howard A. Stine and Richard Scherrer. March 1952. 20p. diagrs. (NACA TN 2664)

A turbulent-boundary-layer temperature recovery factor of 0.885 ± 0.011 was measured on both a 10° cone and a 40° cone cylinder at Mach numbers from 2 to 3.8 and Reynolds numbers based on surface kinematic viscosity from 4×10^5 to 4×10^6. Comparisons are made with available theories and experiments.

NACA TN 2666

TWO-DIMENSIONAL SUBSONIC FLOW PAST ELLIPTIC CYLINDER BY THE VARIATIONAL METHOD. G. V. R. Rao, New York University. March 1952. 39p. diagrs., 3 tabs. (NACA TN 2666)

A method of solution is presented for compressible fluid flow past an elliptic cylinder by means of the variational method. The solution is obtained as a function of thickness ratio and free-stream Mach number. Numerical examples are carried out for several thickness ratios and Mach numbers and the results are compared with those obtained by other methods. It is seen that the variational method yields good results for flow past a thick body at a low Mach number as well as for flow past a thin body at a high Mach number.

NACA RM 51G11

EFFECTIVE MODULUS IN PLASTIC BUCKLING OF HIGH-STRENGTH ALUMINUM-ALLOY SHEET. James A. Miller and Pearl V. Jacobs, National Bureau of Standards. September 1951. 15p. diagrs., 2 tabs. (NACA RM 51G11)

Results of compressive tests on duplicate longitudinal specimens from sheets of 75S-T6 and R301-T aluminum alloys in three thicknesses are presented as graphs of tangent modulus E_t, secant modulus E_s, and $\sqrt{\frac{1}{4} + \frac{3}{4}\frac{E_t}{E_s}}$ plotted against stress on a dimensionless basis. These functions may be used to obtain values of the plasticity coefficients referred to in "A Unified Theory of Plastic Buckling of Columns and Plates" by Elbridge Z. Stowell (NACA Rep. 898). In Stowell's theory the critical stress computed for the elastic case is multiplied by the appropriate plasticity coefficient to give the critical stress for the plastic case.

NACA RM E51G14

EXPERIMENTAL INVESTIGATION OF AN 0.8 HUB-TIP RADIUS-RATIO, NONTWISTED-ROTOR-BLADE TURBINE. David H. Silvern and William R. Slivka. December 1951. 18p. diagrs. (NACA RM E51G14)

An experimental investigation of an 0.8 hub-tip radius ratio, nontwisted-rotor-blade turbine designed for a stagnation-pressure ratio of 2.5 and an equivalent mean blade speed of 643 feet per second was made in a cold-air turbine with (a) nontwisted stator blades, and (b) twisted stator blades designed to maintain zero rotor-inlet incidence angles. Turbine efficiencies of the order of 0.85 at the design point were obtained with a nontwisted-rotor-blade turbine with a hub-tip radius ratio of 0.80. The turbine with the twisted stator blades gave higher efficiencies at the design point (of the order of 1.5 percentage points) than the turbine with the nontwisted stator blades.

NACA TM 1264

CALCULATION OF THE LATERAL-DYNAMIC STABILITY OF AIRCRAFT. (Raschet Bokovoi Dinamicheskoi Ustoichivosti Samolets). A. Raikh. February 1952. 82p. diagrs., 4 tabs. (NACA TM 1264. Trans. from Central Aero-Hydrodynamical Institute, Transactions, No. 453, 1939).

Graphs and formulas are given with the aid of which all the aerodynamic coefficients required for computing the lateral dynamic stability can be determined. A number of numerical examples are given for obtaining the stability derivatives and solving the characteristic-stability equation. Approximate formulas are derived with the aid of which rapid preliminary computations may be made and the stability coefficients corrected for certain modifications of the airplane. A derivation of the lateral-dynamic-stability equations is included.

BOUNDARY LAYER IN COMPRESSIBLE GAS. (Pogranichnyi sloi v szhimaemon gaze). A. Dorodnitsyn. 65p. diagrs., 2 tabs. (Trans. from Prikladnaya Matematika i Mekhanika, v. 6, no. 6, 1942, p. 449-486).

Considers a laminar boundary layer of a compressible gas with absence of heat exchange between the body and the flowing gas. With certain assumptions various methods of boundary-layer theory for noncompressible fluid may be applied to the gas. For the laminar layer, the integral equation analogous to the Kármán equation is given and for its solution the Pohlhausen method is generalized and applied. The cases of plates and bodies of revolution are considered. The generalization of the Blasius-Howarth method is examined. The paper also considers a turbulent boundary layer in a compressible gas. The basic assumptions and expressions for the dynamic values are given.

DECLASSIFIED NACA REPORTS

NACA RM E8F01

PHOTOGRAPHIC STUDY OF COMBUSTION IN A ROCKET ENGINE. I - VARIATION IN COMBUSTION OF LIQUID OXYGEN AND GASOLINE WITH SEVEN METHODS OF PROPELLANT INJECTION. Donald R. Bellman and Jack C. Humphrey. August 26, 1948. 51p. photos., diagrs., tab. (NACA RM E8F01) (Declassified from Restricted, 1/3/52)

Motion pictures up to 3000 frames per second were taken of the combustion of liquid oxygen and gasoline in a 100-pound thrust rocket engine. The effect of seven methods of propellant injection on the uniformity of combustion was investigated. The flame front was generally found to extend to the injector faces and all the injection systems showed considerable nonuniformity of combustion. Pressure vibration records indicated combustion vibrations that corresponded to resonant-chamber frequencies.

NACA RM E50F19

INTERNAL-FILM-COOLING EXPERIMENTS IN 4-INCH DUCT WITH GAS TEMPERATURES TO 2000° F. George R. Kinney and John L. Sloop. September 21, 1950. 34p. diagrs., tab. (NACA RM E50F19) (Declassified from Restricted, 1/3/52)

An investigation of film cooling was conducted in a 4-inch-diameter duct at gas temperatures from 600° to 2000° F and Reynolds numbers from 400,000 to 1,400,000. The coolants were water and ethylene glycol at flows of 1 to 6 percent of the gas flow. During vaporization of the liquid film, coolants kept the duct wall below the boiling temperature of the liquid; little additional duct cooling was obtained from coolant vapor alone. Data were generalized over part of the coolant-flow range by use of heat-transfer relations in a form that facilitates prediction of coolant flow required to film-cool a duct for a desired length when temperature and flow of the hot gas are known.

NACA RM E51C13

INVESTIGATION OF ANNULAR LIQUID FLOW WITH COCURRENT AIR FLOW IN HORIZONTAL TUBES. George R. Kinney and Andrew E. Abramson. May 25, 1951. 33p. diagrs., photos., 2 tabs. (NACA RM E51C13) (Declassified from Restricted, 1/3/52)

Visual observations and flow analyses were made of annular liquid flow with cocurrent air flow in horizontal tubes. Experiments were conducted with air temperatures of 80°, 475°, and 800° F, air-stream Reynolds numbers from 410,000 to 2,900,000, and liquid flows from 0.3 to 21 percent of air flows. Annular liquid films were approximately 0.0005 to 0.005 inch thick. Film surface changed from relatively smooth with the liquid annulus in the region where viscous forces are appreciable to disturbed

where turbulent forces are predominant. Change in cooling effectiveness of liquid films in film-cooling experiments was related to film-surface change; surface condition could be predicted approximately knowing liquid flow and viscosity.

CURRENT NACA REPORTS

NACA Rept. 1016

EFFECT OF TUNNEL CONFIGURATION AND TESTING TECHNIQUE ON CASCADE PERFORMANCE. John R. Erwin and James C. Emery. 1951. ii, 15p. diagrs., photos. (NACA Rept. 1016. Formerly TN 2028)

An investigation has been conducted to determine the influence of aspect ratio, boundary-layer control by means of slots and porous surfaces, Reynolds number and tunnel end-wall condition upon the performance of airfoils in cascades. A representative compressor-blade section (the NACA 65-(12)10) of aspect ratios of 1, 2, and 4 has been tested at low speeds in cascades with solid and with porous side walls. Two-dimensional flow was established in porous-wall cascades of each of the three aspect ratios tested: the flow was not two-dimensional in any of the solid-wall cascades.

NACA Rept. 1032

A COMPARISON OF THEORY AND EXPERIMENT FOR HIGH-SPEED FREE-MOLECULE FLOW. Jackson R. Stalder, Glen Goodwin and Marcus O. Creager. 1951. ii, 22p. diagrs., photos. (NACA Rept. 1032. Formerly NACA TN 2244)

A comparison is made of free-molecule-flow theory with the results of wind-tunnel tests performed to determine the drag and temperature-rise characteristics of a transverse circular cylinder. The measured values of the cylinder center-point temperature confirmed the salient point of the heat-transfer analysis which was the prediction that an insulated cylinder would attain a temperature higher than the stagnation temperature of the stream. Good agreement was obtained between the theoretical and the experimental values for the drag coefficient.

NACA Rept. 1033

COMPARISON BETWEEN THEORY AND EXPERIMENT FOR WINGS AT SUPERSONIC SPEEDS. Walter G. Vincenti. 1951. ii, 11p. diagrs., photos. (NACA Rept. 1033. Formerly TN 2100)

A critical comparison is presented between experimental and theoretical results for the aerodynamic characteristics of wings at supersonic flight speeds. After a brief review of supersonic wing theory and of previous results from two-dimensional pressure-distribution tests, an account is given of an NACA study of the force characteristics of three dimensional wings at supersonic speed. Typical experimental and theoretical results are presented for the lift, pitching-moment, and drag characteristics of several families of wings of varying plan form and section. The regions of agreement and disagreement between experiment and theory are noted and discussed.

NACA Rept. 1034

INVESTIGATION OF SPOILER AILERONS FOR USE AS SPEED BRAKES OR GLIDE-PATH CONTROLS ON TWO NACA 65-SERIES WINGS EQUIPPED WITH FULL-SPAN SLOTTED FLAPS. Jack Fischel and James M. Watson. 1951. ii, 25p. diagrs. (NACA Rept. 1034. Formerly TN 1933)

Contains results and discussion of an investigation of plug and retractable ailerons used as speed brakes or glide-path controls on an NACA 65-210 wing and an NACA 65_2-215 wing of aspect ratio 5.76 equipped with full-span slotted flaps. Incremental lift, drag, and pitching-moment data are presented for various flap conditions through a large angle-of-attack range at Mach numbers from 0.13 to 0.71. Analysis indicates that this use of spoiler ailerons is feasible and desirable for normal or emergency operation of airplanes. These speed brakes or glide-path controls would probably have small effect on wing pitching moments and should retain their rolling effectiveness.

NACA TN 2598

A TECHNIQUE APPLICABLE TO THE AERODYNAMIC DESIGN OF INDUCER-TYPE MULTISTAGE AXIAL-FLOW COMPRESSORS. Melvyn Savage and Loren A. Beatty. March 1952. ii, 62p. diagrs., 8 tabs. (NACA TN 2598)

A method is presented for the preliminary design of high-pressure-ratio multistage axial-flow compressors using the solid-body inducer design in which the first stage has the radial total-temperature distribution required to make the second-stage inlet axial velocity constant radially. The remaining stages have constant power input radially, solid-body average tangential velocities, and radially constant inlet axial velocities. Typical preliminary design calculations are presented for inlet hub-tip ratios of 0.40, 0.50, and 0.60 with weight flows ranging from 20.0 to 32.5 pounds per second per square foot of frontal area and average pressure ratios per stage ranging from 1.28 to 1.38. Some of the effects of specific weight flow, rotational speed, hub-tip ratio, turning angle, and inlet air angle on power input, amount of

radial flow, and over-all pressure ratio are investigated.

NACA TN 2640

INTERACTION OF COLUMN AND LOCAL BUCKLING IN COMPRESSION MEMBERS. P. P. Bijlaard and G. P. Fisher, Cornell University. March 1952. 110p. diagrs., photos., 4 tabs. (NACA TN 2640)

Simple formulas are obtained which express the actual buckling stress directly in terms of the column or plate buckling stresses. Columns with box, I-, H-, and T-sections and angles are considered separately. Interaction of practically significant magnitude occurs only in cases of flexural and torsional buckling. In these cases the additional effect of distorsion of the cross section is also taken into account. The theory includes buckling in the plastic range. Tests were carried out for a considerable range of ratios of corrected free length to radius of gyration on two sections, for one of which the local buckling stress was in the plastic, and for the other, in the elastic, domain. The experimental buckling stresses are in excellent agreement with those predicted by the theory.

NACA TN 2665

AN EXTENSION OF LIFTING ROTOR THEORY TO COVER OPERATION AT LARGE ANGLES OF ATTACK AND HIGH INFLOW CONDITIONS. Alfred Gessow and Almer D. Crim. April 1952. 36p. diagrs. (NACA TN 2665)

The report derives analytical expressions for the flapping, thrust, torque, and profile-drag power of a hinged rotor in which the small-angle limitations and the assumption of nonstalled flow in the reversed-velocity region of standard rotor theory are removed. The equations are thus applicable to high-speed helicopters and to certain types of convertible aircraft.

NACA TN 2667

GENERALIZED LINEARIZED CONICAL FLOW. W. D. Hayes, R. C. Roberts and N. Haaser, Brown University. March 1952. 48p. diagrs., tab. (NACA TN 2667)

A basic theory of generalized linearized supersonic conical flow for both inside and outside the Mach cone was developed and applied to several specific problems including unsteady-flow conditions. A triangular lifting wing in pitching and rolling with both subsonic and supersonic leading edges was investigated and pressure coefficients were obtained. A family of thin sweptback triangular wings having symmetrical thickness distribution was also investigated and analytic expressions for wave drag and pressure coefficients were determined. Values of wave-drag coefficients were calculated and the results presented graphically.

NACA TN 2668

EXPERIMENTAL INVESTIGATION OF A 90° CASCADE DIFFUSING BEND WITH AN AREA RATIO OF 1.45:1 AND WITH SEVERAL INLET BOUNDARY LAYERS. Daniel Friedman and Willard R. Westphal. April 1952. 30p. diagrs., photos., 2 tabs. (NACA TN 2668)

An experimental investigation was conducted in order to determine the performance of a 90° cascade diffusing bend with an area ratio of 1.45:1 and a 19-inch-square inlet with several inlet-boundary-layer shapes and thicknesses. The maximum mean inlet Mach number was 0.41 and the corresponding airfoil Reynolds number was 950,000. The experimental results seem to indicate that, when the duct configuration requires a bend, a certain amount of diffusion can be obtained without an appreciable rise in the total-pressure losses. If length is important, this configuration requires much less space than the usual diffuser-bend combination.

NACA TN 2669

APPROXIMATE THEORY FOR CALCULATION OF LIFT OF BODIES, AFTERBODIES, AND COMBINATIONS OF BODIES. Barry Moskowitz. April 1952. 39p. diagrs. (NACA TN 2669)

An expression is developed for the lift of a slender afterbody in terms of the "slender-body" approximate potential at the after end in conjunction with a suitably calculated value of the potential at the forward end. The failure of the usual "slender-body" theory to predict any lift on a slender cylindrical afterbody is thereby corrected. The same expression is used to compute the part of the interference lift generated by the presence of a neighboring body, due to the interference upwash. Another expression is developed to compute the remainder of the interference lift, due to an interference pressure gradient. The lift is determined for a cone-cylinder body, a cylindrical afterbody of a slender wing-body combination, and three combinations of bodies to illustrate the method.

NACA TN 2671

INVESTIGATION OF STRESS DISTRIBUTION IN RECTANGULAR PLATES WITH LONGITUDINAL STIFFENERS UNDER AXIAL COMPRESSION AFTER BUCKLING. Chi-Teh Wang and Harry Zuckerberg, New York University. March 1952. 61p. diagrs. (NACA TN 2671)

An investigation was carried out to study the elastic behavior after buckling of a rectangular plate reinforced with longitudinal stiffeners and subjected to compressive loads in a direction parallel to the stiffeners. Two possible buckling modes were investigated, namely, that in which the plate buckles around the stiffeners as nodal lines and that in which the plate buckles with the intermediate stiffeners as a unit. For the first buckling mode the calculated results were compared with experimental results and the agreement was found to be good. The method of analysis used is a modified variational procedure; this was found to give much better results with the same amount of computational labor.

NACA TN 2673

THEORETICAL PERFORMANCE OF AN AXIAL-FLOW COMPRESSOR IN A GAS-TURBINE ENGINE OPERATING WITH INLET WATER INJECTION. Reece V. Hensley. March 1952. 25p. diagrs. (NACA TN 2673)

The performance of an axial-flow compressor operating in a gas-turbine engine with inlet water injection and compressor-outlet saturation was theoretically evaluated. Changes in compressor pressure ratio, compressor efficiency, and compressor work due to water injection were determined for altitudes up to 50,000 feet, Mach numbers up to 2.0, and normal compressor pressure ratios of 4, 8, and 16.

NACA TN 2679

THE STABILITY UNDER LONGITUDINAL COMPRESSION OF FLAT SYMMETRIC CORRUGATED-CORE SANDWICH PLATES WITH SIMPLY SUPPORTED LOADED EDGES AND SIMPLY SUPPORTED OR CLAMPED UNLOADED EDGES. Paul Seide. April 1952. 27p. diagrs. (NACA TN 2679)

A theory for the elastic behavior of orthotropic sandwich plates is used to determine the compressive buckling-load parameters of flat symmetrical corrugated core sandwich plates with simply supported loaded edges and simply supported or clamped unloaded edges.

NACA TN 2680

FLAME SPEEDS OF 2, 2, 4-TRIMETHYLPENTANE-OXYGEN-NITROGEN MIXTURES. Gordon L. Dugger and Dorothy D. Graab. April 1952. 25p. diagrs., photo., 2 tabs. (NACA TN 2680)

Flame speeds of homogeneous 2,2,4-trimethylpentane-oxygen-nitrogen mixtures were determined as functions of mixture composition at two or three initial temperatures by a Bunsen-burner method. Oxygen-nitrogen mixtures containing 0.210 to 0.496 mole fraction of oxygen were used. Maximum flame speed increased linearly with oxygen concentration for each initial temperature. An empirical equation including the effects of initial temperature and oxygen concentration was obtained. Both a thermal and a diffusion theory predicted the relative effect of oxygen concentration on maximum flame speed within 20 percent. No linear correlations between maximum flame speed and calculated active particle concentrations were obtained.

NACA TN 2681

A COMPRESSIBLE-FLOW PLOTTING DEVICE AND ITS APPLICATION TO CASCADE FLOWS. Willard R. Westphal and James C. Dunavant. April 1952. 21p. diagrs., photos. (NACA TN 2681)

A simplified method has been devised for the solution of two-dimensional compressible flows through well-defined passages. This method makes use of plastic cams which automatically set the length-to-width ratio of rectangles formed by streamlines and equipotential lines represented by spring-steel wires. Pressure distribution around four cascades of turbine blades and along the surface of a choked nozzle determined by this method are shown to compare well with experimental results.

NACA TN 2682

TRANSVERSE VIBRATIONS OF HOLLOW THIN-WALLED CYLINDRICAL BEAMS. Bernard Budiansky and Edwin T. Kruszewski. April 1952. 29p. diagrs. (NACA TN 2682)

The variational principle, differential equations, and boundary conditions considered appropriate to the analysis of transverse vibrations of hollow cylindrical beams are shown. General solutions for the modes and frequencies of cantilever and free cylindrical beams of arbitrary cross section but of uniform thickness are given. The combined influence of the secondary effects of transverse shear deformation, shear lag, and longitudinal inertia is shown in the form of curves for cylinders of rectangular cross section and uniform thickness. The contribution of each of the secondary effects to the total reduction in the actual frequency is also indicated.

NACA TN 2686

EXPERIMENTAL INVESTIGATION OF HEAT TRANSFER THROUGH LAMINAR AND TURBULENT BOUNDARY LAYERS ON A COOLED FLAT PLATE AT A MACH NUMBER OF 2.4. Ellis G. Slack. April 1952. 31p. diagrs. (NACA TN 2686)

Wind-tunnel tests of the heat-transfer characteristics for laminar and turbulent boundary layers on a cooled flat plate were conducted at a Mach number of 2.4.

Data were obtained for a Reynolds number range of 1.5×10^5 to 3×10^6 and for a surface-temperature range of -40° F to 45° F with recovery temperature of the order of 65° F. The temperature-recovery factors agreed well with previous flat-plate results. The heat-transfer results were obtained with negative temperature gradients along the surface and, when related to the constant-surface-temperature case, were, in general, in good agreement with theory.

NACA TN 2687

APPLICATION OF TRANSONIC SIMILARITY. Adolf Busemann. April 1952. 22p. diagrs. (NACA TN 2687)

From a review of the different similarity approaches to compressible potential flow, the meaning and limitations of transonic similarity are traced back to their origin. Although the main text deals with the quasi two-dimensional flow, special suggestions for the case of axisymmetrical bodies are added in an appendix.

NACA RM L52B04

GUST-TUNNEL INVESTIGATION OF DELTA-WING MODEL WITH THE LEADING EDGE SWEPT BACK 60°. Harold B. Pierce and Slaton L. Johns. April 1952. 12p. diagrs., photo., 3 tabs. (NACA RM L52B04)

A gust-tunnel investigation of a delta-wing model with the leading edge swept back 60° has indicated that the gust load is greater than would be predicted by using a slope of the lift curve determined from steady-flow force tests. The use of a slope of a lift curve derived from simple aspect-ratio considerations resulted in a good estimate of the load.

NACA TM 1318
National Advisory Committee for Aeronautics.
FRICTION AND WEAR. (Le frottement et l'usure). J. Pomey. March 1952. 108p. diagrs., photos., 12 tabs. (NACA TM 1318. Trans. from Office National d'Études et de Recherches Aéronautiques, Rapport Technique 36, 1948; Groupement Francais pour le Développement des Recherches Aéronautiques).

This report covers a general survey of the field of friction and wear. This survey includes discussions of hydrodynamic lubrication, boundary lubrication, seizure and dry friction. Definitions are derived, fundamentals are discussed in considerable detail, and the effects of surface films (adsorbed lubricants or chemically reacted compounds) are studied. Some experimental results are also included.

NACA TM 1336

DEVELOPMENT OF A LAMINAR BOUNDARY LAYER LAYER BEHIND A SUCTION POINT. (Entwicklung einer laminaren grenzschicht hinter einer absaugestelle). W. Wuest. March 1952. 18p. diagrs. (NACA TM 1336. Trans. from Ingenieur-Archiv, v. 17, 1949, p.199-206).

A theoretical investigation is made of the development of a laminar boundary layer behind a suction slot that is assumed to cut off part of the boundary layer without exerting any sink effect. The development, which is approximate, is based on the heat conduction equation. The heat conduction equation enters the analysis through a linearization of the Prandtl-Mises form of the boundary-layer equation.

National Gas Turbine Establishment (Gt. Brit.)
AIR COOLING METHODS FOR GAS TURBINE COMBUSTION SYSTEMS. F. J. Bayley. August 1951. 44p. diagrs. (NGTE R.101)

Presents an account of the whole of the work which has been done at N.G.T.E. on the problem of cooling gas turbine combustion systems. Each of the different methods of wall cooling is discussed separately and the theory and mechanism of the cooling process is developed from first principles. Sufficient information is given to enable any of the various methods to be applied to practical wall cooling problems. A comparison is made between the effectiveness of the cooling systems and their relative advantages and disadvantages for different gas turbine applications are discussed.

Royal Aircraft Establishment (Gt. Brit.)
A CONTRIBUTION TO NON-LINEAR MECHANICS GRAPHICAL INTEGRATION OF EQUATIONS OF THE TYPE $\ddot{X} + F(X)\dot{X} + X = 0$. F. Holoubek. November 1951. 19p. diagrs., photos. (RAE Tech. Note Mech. Eng. 99)

The equation $\ddot{x} + f(x)\dot{x} + x = 0$ is characteristic of the motion of an oscillatory system in which the damping is a function of the displacement. In systems largely departing from linearity the quasi-harmonic solution becomes rather inaccurate. This paper describes a graphical method of double integration of the equation, made relatively simple by the use of two elementary computing aids. A method of "linearization" of the general equation in certain cases is also discussed.

N-14086*

National Gas Turbine Establishment (Gt. Brit.)
THE N.G.T.E. MODEL-DISC SPINNING-RIG, AND THE EFFECT OF BORE AND BOLT-HOLES ON BURSTING SPEEDS. A. Graham and V. C. H. Bailey. May 1951. 29p. diagrs., photos., 3 tabs. (NGTE R. 91)

A description is given of a spinning rig driven by an air turbine capable of bursting disks of up to about 8 inches diameter and 4 pounds in weight. Bursting experiments on disks in an as-cast aluminum alloy, chosen for its uniformity and isotropy, gave a consistent value for the reduction of bursting speed due to an uncompensated hole, and this agreed with the mean of a range of values found by other workers who used a variety of materials. Various peculiarities are found to be explicable in general terms, and the conclusion is drawn that experimental variations in the weakening due to a hole, and the amount by which bursting speed differs from that to be expected from a calculated elastic distribution of stress, may be due to specified differences in the stress/strain properties of the materials which are not revealed by conventional measures of ductility.

Pennsylvania State Coll. Engineering Experiment Station. BENDING OF THIN PLATES WITH SMALL COMPOUND CURVATURE. H. G. Lew and J. A. Fox. August 28, 1951. 58p. diagrs., photo., 8 tabs. (Pennsylvania State Coll. Engineering Experiment Station)

An analysis is presented of the behavior of thin plates with a small amount of initial curvature under edge loads. Small deflection problems of the plate were considered. For these problems, a number of closed form solutions are presented; and, in addition the Rayleigh-Ritz method was used where closed form solutions are not possible. Some tests were made. The results for small initial curvature compared favorably with theoretical results. Methods are presented in the form that they can be applied readily to the solution of thin plates under edge loads or surface loads.

NACA RM A9E31

TESTS OF THE NACA 64-010 AND 64A010 AIRFOIL SECTIONS AT HIGH SUBSONIC MACH NUMBERS. Albert D. Hemenover. July 8, 1949. 19p. diagrs., tab. (NACA RM A9E31) (Declassified from Restricted, 3/10/52)

Aerodynamic characteristics of the NACA 64-010 and 64A010 airfoil sections are compared from wind-tunnel tests at Mach numbers from 0.3 to 0.9.

NACA RM E8J13

INVESTIGATION OF A VARIABLE MACH NUMBER SUPERSONIC TUNNEL WITH NONINTERSECTING CHARACTERISTICS. John C. Evvard and DeMarquis D. Wyatt. November 15, 1948. 28p. diagrs., photos., tab. (NACA RM E8J13) (Declassified from Confidential, 3/10/52)

A method is presented for the design of supersonic wind-tunnel nozzles that produce uniform flow over a continuously variable Mach number range without the use of flexible walls. Experimental results obtained from a preliminary investigation of such a tunnel are included. Mach numbers were obtained in the range of 1.75 to 2.65 with less than 1-percent variation in Mach number in the test section downstream of an over-expansion region observed in the neighborhood of the nozzle throat.

NACA RM E8L10

PERFORMANCE OF SUPERSONIC AXIAL-FLOW COMPRESSORS BASED ON ONE-DIMENSIONAL ANALYSIS. Linwood C. Wright and John F. Klapproth. March 25, 1949. 29p. diagrs. (NACA RM E8L10) (Declassified from Confidential, 3/28/52)

A general analysis of the computed pressure ratio and mass flow of four practical types of single-stage axial-flow supersonic compressor is given. The ultimate performance of supersonic compressors is not discussed. Instead the factors limiting present design are considered in order to outline the performance that seems obtainable in the best design based on present knowledge of the four configurations.

NACA RM E9I21

TEMPERATURE SURVEY OF THE WAKE OF TWO CLOSELY LOCATED PARALLEL JETS. John L. Sloop and Gerald Morrell. February 6, 1950. 37p. diagrs., photos., 8 tabs. (NACA RM E9I21) (Declassified from Confidential, 3/10/52)

A temperature survey was made of the wake of two closely located parallel jets emerging into the atmosphere from two types of twin convergent nozzle: (1) 1-inch-diameter throats with centers 1.42 inches apart, and (2) 0.863-inch-diameter throats with centers 1.5 inches apart followed by simulated 1-inch-diameter shrouds 0.466 inch long. Expansion ratio was 9.7; average jet total temperature, 1334° F; and ratio of specific heats, about 1.27. In the case of jets issuing from shrouded nozzles, less interaction occurred than for jets issuing from unshrouded nozzles.

NACA RM E9L01

TEMPERATURE AND PRESSURE DISTRIBUTIONS IN DUAL PARALLEL JETS IMPINGING ON THE GROUND FROM A TURBOJET ENGINE. J. Elmo Farmer, Francis S. Stepka and Floyd B. Garrett. February 20, 1950. 23p. diagrs., photo. (NACA RM E9L01) (Declassified from Confidential, 3/10/52)

An investigation was conducted to determine the temperature and pressure distributions in dual jets of a

turbojet engine located close together and impinging on the ground at an angle of 20°. The temperature and pressure profiles obtained in the investigation indicate that a pronounced mutual interference between the two parallel jets beyond 1 diameter downstream of the nozzle exits caused the gases to expand upward between the two jets. The jet boundary was found to be farther above the ground between the two jets than it was directly behind them.

NACA RM L7L29

THE NACA 2000-HORSEPOWER PROPELLER DYNAMOMETER AND TESTS AT HIGH SPEED OF AN NACA 10-(3)(08)-03 TWO-BLADE PROPELLER. Blake W. Corson, Jr. and Julian D. Maynard. July 20, 1948. 85p. diagrs., photos., 3 tabs. (NACA RM L7L29) (Declassified from Restricted, 3/28/52)

Contains detailed description of a 2000-horsepower propeller dynamometer used to make wind-tunnel tests of a two-blade NACA 10-(3)(08)-03 propeller for a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour. The results of these tests and comparisons with results obtained from a theoretical analysis and from previous tests made in other wind tunnels are presented.

NACA RM L8E26

AERODYNAMIC CHARACTERISTICS AT HIGH SPEEDS OF A TWO-BLADE NACA 10-(3)(062)-045 PROPELLER AND OF A TWO-BLADE NACA 10-(3)(08)-045 PROPELLER. William Solomon. October 1, 1948. 54p. diagrs., photo., tab. (NACA RM L8E26) (Declassified from Confidential, 3/28/52)

Characteristics are given for the two-blade NACA 10-(3)(062)-045 propeller and for the two-blade NACA 10-(3)(08)-045 propeller over a range of advance ratio from 0.5 to 3.8, the blade-angle range covering 20° to 55° measured at the 0.75 radius. Maximum efficiencies of the order of 91.5 to 92 percent were obtained for the propellers. The propeller with the thinner airfoil sections over the outboard portion of the blades, the NACA 10-(3)(062)-045 propeller, had lower losses at high tip speeds, the difference amounting to about 5 percent at a helical tip Mach number of 1.10.

NACA RM L8G19

WIND-TUNNEL INVESTIGATION AT LOW SPEEDS OF THE PITCHING DERIVATIVES OF UNTAPERED SWEPT WINGS. Robert MacLachlan and Lewis R. Fisher. September 29, 1948. 22p. diagrs., photo., tab. (NACA RM L8G19) (Declassified from Restricted, 3/10/52)

Contains wind-tunnel results of the independent effects of varying aspect ratio and angle of sweep on the longitudinal rotary stability derivatives of a series of untapered wings tested in pitching flow. Comparison is made of experimental and theoretical results.

NACA RM L8H10

EFFECT OF AIRFOIL PROFILE OF SYMMETRICAL SECTIONS ON THE LOW-SPEED STATIC-STABILITY AND YAWING DERIVATIVES OF 45° SWEPTBACK WING MODELS OF ASPECT RATIO 2.61. William Letko and Byron M. Jaquet. November 9, 1948. 21p. diagrs., photo., tab. (NACA RM L8H10) (Declassified from Restricted, 3/10/52)

Contains results of tests made in the Langley stability tunnel for determining the effects of airfoil profile of symmetrical sections on the low-speed static-stability and yawing derivatives of untapered 45° sweptback wing models of aspect ratio 2.61. The wings had the following profiles normal to the leading edge: biconvex (12 percent thick), NACA 65_1-012, and NACA 0012.

NACA RM L8J07

THE EFFECT OF NEGATIVE DIHEDRAL, TIP DROOP, AND WING-TIP SHAPE ON THE LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A COMPLETE MODEL HAVING A 45° SWEPTBACK WING. M. Leroy Spearman and Robert E. Becht. December 6, 1948. 50p. diagrs., photo., tab. (NACA RM L8J07) (Declassified from Restricted, 3/10/52)

An investigation has been conducted in the Langley 300-mph 7- by 10-foot tunnel to determine the effect of negative dihedral, tip droop, and wing-tip shape on the low-speed aerodynamic characteristics of a complete model having a 45° sweptback wing. Longitudinal and lateral stability characteristics were obtained for the model with and without tail surfaces.

NACA RM L8L31a

EFFECT OF AIRFOIL PROFILE OF SYMMETRICAL SECTIONS ON THE LOW-SPEED ROLLING DERIVATIVES OF 45° SWEPTBACK-WING MODELS OF ASPECT RATIO 2.61. William Letko and Jack D. Brewer. March 4, 1949. 27p. diagrs., photo., 2 tabs. (NACA RM L8L31a) (Declassified from Restricted, 3/10/52)

Contains results of tests made in the Langley stability tunnel to determine the effects of airfoil profile of symmetrical sections on the low-speed rolling derivatives of untapered 45° sweptback-wing models of 2.61 aspect ratio. The wings had the following profiles normal to the leading edge: biconvex (12 percent thick), NACA 65_1-012, and NACA 0012. Also contains calculations of stability boundaries and motions at subsonic speeds of a transonic airplane configuration using the different wing profiles.

NACA RM L9D29

THE EFFECT OF BLADE-SECTION THICKNESS RATIOS ON THE AERODYNAMIC CHARACTERISTICS OF RELATED FULL-SCALE PROPELLERS AT MACH NUMBERS UP TO 0.65. Julian D. Maynard and Seymour Steinberg. June 6, 1949. 90p. diagrs., photos., tab. (NACA RM L9D29) (Declassified from Confidential, 3/28/52)

Results of an investigation of two full-scale NACA propellers are presented for a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour. These results are compared with the results from previous tests of five related NACA propellers to evaluate the effects of blade-section thickness ratios on propeller aerodynamic characteristics.

NACA RM L50I13
National Advisory Committee for Aeronautics.
INVESTIGATION OF THE PRESSURE-RATIO REQUIREMENTS OF THE LANGLEY 11-INCH HYPERSONIC TUNNEL WITH A VARIABLE-GEOMETRY DIFFUSER. Mitchel H. Bertram. October 6, 1950. 19p. diagrs. (NACA RM L50I13) (Declassified from Confidential, 3/10/52)

Tests were conducted in the Langley 11-inch hypersonic tunnel at a Mach number of 6.86 to determine the stagnation pressure ratios across the system required to maintain supersonic flow with the use of a variable-geometry diffuser. With such a diffuser, it was possible in some cases to reduce the pressure ratio required to maintain flow to about one-third of that required for starting with a consequent quadrupling of the duration of test run.

CURRENT NACA REPORTS

NACA TN 2644

EXPERIMENTAL INVESTIGATION OF AN NACA 64A010 AIRFOIL SECTION WITH 41 SUCTION SLOTS ON EACH SURFACE FOR CONTROL OF LAMINAR BOUNDARY LAYER. Dale L. Burrows and Milton A. Schwartzberg. April 1952. 37p. diagrs., photos. (NACA TN 2644)

A wind-tunnel investigation of an NACA 64A010 airfoil model with 41 suction slots per surface indicated that laminar flow could be obtained over 0.91 chord on one surface up to a Reynolds number of 10×10^6 with an estimated net drag saving of about 50 percent over the plain smooth airfoil. Extensive laminar flow could not be obtained at higher Reynolds numbers because of increased sensitivity of the flow to minute surface irregularities and slight inaccuracies of slot-entry contour.

NACA TN 2659

A MINATURE ELECTRICAL PRESSURE GAGE UTILIZING A STRETCHED FLAT DIAPHRAGM. John L. Patterson. April 1952. 47p. diagrs., photos., 2 tabs. (NACA TN 2659)

A variable-air-gap, inductance-type, electrical pressure gage is described that is basically 7/16 inch in diameter and 1/4 inch in thickness. The gage was designed to measure accurately pressures fluctuating at high frequencies and has proved to be of value as a general-purpose electrical gage for aeronautical work where small size and minimum response to acceleration forces are important factors. Design equations and curves are presented which can be used to predict the deflections and fundamental natural frequencies of stretched flat diaphragms.

NACA TN 2677

WING-BODY INTERFERENCE AT SUPERSONIC SPEEDS WITH AN APPLICATION TO COMBINATIONS WITH RECTANGULAR WINGS. Jack N. Nielsen and William C. Pitts. April 1952. 63p. diagrs., 2 tabs. (NACA TN 2677)

An exact theoretical method is developed that permits the determination of the pressure field of a wing-body combination having a circular body and wings with supersonic leading and trailing edges. Detailed calculations are performed for the case of a rectangular wing or all-movable control surface on a body at zero angle of attack. Design charts are presented showing the effect of interference on the lift and center-of-pressure position of the wings. The physical basis of the interference is discussed.

NACA TN 2678

ABNORMAL GRAIN GROWTH IN S-816 ALLOY. A. I. Rush, J. W. Freeman and A. E. White, University of Michigan. April 1952. 30p. photos., diagrs., tab. (NACA TN 2678)

Preliminary results are presented from an investigation to establish the fundamental causes of abnormal grain growth in S-816 alloy under conditions encountered during forging of blades for aircraft gas turbines. The data are confined to experiments to produce abnormally large grains in bar stock under controlled conditions. It was found that critical deformation for grain growth is apparently independent of temperature of deformation; repeated critical deformations between reheats to 2150° F produce much larger grains than a single critical deformation; grain growth characteristics are sensitive to prior history; and abnormal grain growth can be induced by temperature cycling alone to temperatures of 2150° F with certain prior histories.

NACA TN 2684

A LOW-SPEED INVESTIGATION OF A FUSELAGE-SIDE AIR INLET FOR USE AT TRANSONIC FLIGHT SPEEDS. Mark R. Nichols and Edwin B. Goral. April 1952. 60p. diagrs., photos., tab. (NACA TN 2684. Formerly RM L7A06)

Low-speed pressure-recovery and surface-pressure measurements for a twin fuselage-side air-inlet arrangement intended for use at transonic speeds are presented. The model was developed by adding a canopy and nose-wheel fairing to basic transonic annular inlet studied in TN 2685. The results indicate shape requirements of fuselage nose, canopy, and nose-wheel fairing for maintaining substream surface velocities everywhere ahead of entrance.

NACA TN 2685

A LOW-SPEED INVESTIGATION OF AN ANNULAR TRANSONIC AIR INLET. Mark R. Nichols and Donald W. Rinkoski. April 1952. 38p. diagrs., photos. (NACA TN 2685. Formerly RM L6J04)

Low-speed wind-tunnel tests were conducted as preliminary steps in the study of fuselage-air-inlet

AVAILABLE ON LOAN ONLY.
DDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C, CITING CODE NUMBER ABOVE EACH TITLE, HE REPORT TITLE AND AUTHOR.

arrangements believed suitable for use at transonic speeds. The forward part of the model consisted of an NACA 1-85-050 cowling located at the base of the long protruding fuselage nose designed to maintain substream surface velocities everywhere ahead of the entrance and thereby to avoid or minimize adverse boundary-layer-shock interaction effects up to low supersonic speeds. Pressure-recovery and surface-pressure measurements are presented for the model with three fuselage nose shapes for ranges of angle of attack and inlet-velocity ratio useful for high-speed flight.

NACA TN 2691

THEORETICAL AND EXPERIMENTAL ANALYSIS OF ONE-DIMENSIONAL COMPRESSIBLE FLOW IN A ROTATING RADIAL-INLET IMPELLER CHANNEL. Seymour Lieblein. April 1952. 47p. diagrs., photo. (NACA TN 2691)

An analysis of the one-dimensional compressible flow in a radial-inlet impeller channel was conducted in order to provide an insight into the characteristics of the passage mean flow. A theoretical investigation of the flow in an illustrative impeller channel showed the general flow behavior, location of critical section and effect of losses in an impeller channel. A further analysis was conducted of the one dimensional flow in a previously reported experimental radial-inlet impeller. The general flow behavior, effective flow area, inlet throat formation, maximum flow, and loss variations were analyzed.

NACA TM 1317

A SIMPLE NUMERICAL METHOD FOR THE CALCULATION OF THE LAMINAR BOUNDARY LAYER. (Ein einfaches numerisches Verfahren zur Berechnung der laminaren Grenzschicht). K. Schröder. April 1952. 47p. diagrs., 3 tabs. (NACA TM 1317. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1741; Deutsche Versuchsanstalt für Luftfahrt E. V., Berlin. Institut für Aerodynamik, February 25, 1943.)

An iteration difference method for the calculation of the incompressible laminar boundary layer is described. The method uses Prandtl's boundary layer equation and the boundary conditions directly and permits the attainment of an arbitrary accuracy. The method has been tested successfully in the continuation of the Blasius profile on the flat plate, on the circular cylinder investigated by Heimenz and on an elliptical cylinder of fineness ratio 1:4. The method makes possible the testing of previously developed methods, all of which contain important assumptions.

National Gas Turbine Establishment (Gt. Brit.)
STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART III. THE EFFECT OF CHEMICAL FACTORS UPON THE IGNITION DELAY OF KEROSINE-AIR MIXTURES. B. P. Mullins. October 1951. 57p. 31 tabs., diagrs. (NGTE R. 95)

Ignition delay measurements at atmospheric pressure were carried out in the 3° diffuser rig described in NGTE Report R. 89 using kerosene containing various additives. Regarding the fuel composition, for air temperatures in the range 750°-1000° C, it was found that the following additives had little effect upon the ignition delays of kerosene and that in no case was 50-percent reduction observed: 5-percent diethylether, 5-percent propylene oxide, 5-percent nitrobenzene, 2-percent tertiarybutylhydroperoxide, 5-percent acetaldehyde, 5-percent carbon disulphide (v/v), 4-percent ferric stearate, 5-percent cobalt stearate, and 5-percent cupric stearate (w/w). Of these additives the first three were the most effective. Ethyl nitrate, amyl nitrite and ethyl nitrite when added to kerosene in high concentrations were found to cause very large reductions in ignition delay, the magnitude of which depended upon the additive concentration, as also did the slope of the ignition delay versus temperature curves. Ethyl nitrate had by far the largest effect of any of the additives tested. The two nitrous esters were less effective than diethylether at 5-percent concentrations.

NACA TN 2484

EFFECT OF COMPRESSIBILITY ON THE FLOW PAST A TWO-DIMENSIONAL BUMP. W. F. Lindsey and Bernard N. Daley. April 1952. 34p. diagrs., photos. (NACA TN 2484. Formerly RM L6K12b)

An investigation has been conducted to determine experimentally the effects of compressibility on the flow past a bump and to compare the experimentally determined results with theory. Pressure measurements and schlieren photographs were made of the flow past two bumps having thickness-chord ratios of 0.10 and 0.30 at Mach numbers between 0.20 and 0.84.

NACA TN 2660

AN APPROACH TO THE PREDICTION OF THE FREQUENCY DISTRIBUTION OF GUST LOADS ON AIRPLANES IN NORMAL OPERATIONS. Harry Press. April 1952. 34p. diagrs., 2 tabs. (NACA TN 2660)

As a basis for the prediction of the gust-load history of airplanes in service operations, the statistical concepts of random variables and probability distributions are applied to the "sharp edge gust" formula. Expressions are derived for the frequency distribution of gust loads in terms of distributions of the related variables such as effective gust velocity and airspeed. Solutions are obtained under assumptions that appear reasonable on the basis of present practices in gust research. The results are applied in an example and the predicted load experience is compared with the available flight loads data for this case.

NACA TN 2661

A SUMMARY OF DIAGONAL TENSION. PART I - METHODS OF ANALYSIS. Paul Kuhn, James P. Peterson and L. Ross Levin. May 1952. v, 131p. diagrs., photo. (NACA TN 2661)

Previously published methods for stress and strength analysis of plane and curved shear webs working in diagonal tension are presented as a unified method. The treatment is sufficiently comprehensive and detailed to make the paper self-contained. Part I discusses the theory and methods for calculating the stresses and shear deflections of web systems as well as the strengths of the web, the stiffeners, and the riveting. Part II, published separately, presents the experimental evidence.

NACA TN 2662

A SUMMARY OF DIAGONAL TENSION. PART II - EXPERIMENTAL EVIDENCE. Paul Kuhn, James P. Peterson and L. Ross Levin. May 1952. ii, 81p. diagrs., photos., 8 tabs. (NACA TN 2662)

Methods of analyzing web systems working in diagonal tension have been given in Part I of this paper. Part II presents the experimental evidence.

NACA TN 2663

THE GUST AND GUST-LOAD EXPERIENCE OF A TWIN-ENGINE LOW-ALTITUDE TRANSPORT AIRPLANT IN OPERATION ON A NORTHERN TRANSCONTINENTAL ROUTE. Harry Press and Robert L. McDougal. April 1952. 33p. diagrs., 8 tabs. (NACA TN 2663)

An analysis of the gust and gust-load experience of a low-altitude transcontinental transport airplane, based on 834 hours of VGH record, is presented. The relation of gust experience to airspeed, altitude, season of the year, and flight condition is considered. An estimate of the over-all gust history for the present type of operations is derived from a synthesis of the VGH data and available V-G data.

NACA TN 2674

SOME EXPERIMENTS ON VISUALIZATION OF FLOW FIELDS BEHIND LOW-ASPECT-RATIO WINGS BY MEANS OF A TUFT GRID. John D. Bird and Donald R. Riley. May 1952. 32p. photos., diagrs., tab. (NACA TN 2674)

A technique for obtaining a physical picture of the flow behind lifting surfaces is described wherein the action of a large number of tufts of uniform length attached to a wire grid are photographed from far downstream. This procedure yields, with a minimum of labor, an approximate vector plot of the flow field in a plane normal to the air stream. The flow fields behind a rectangular wing and several triangular wings were investigated through the angle-of-attack range. The effects of tip-control deflection, sideslip, and oscillation in sideslip on the flow field behind a 60° triangular wing were also determined.

NACA TN 2683

SURVEY OF PORTIONS OF THE CHROMIUM-COBALT-NICKEL-MOLYBDENUM QUATERNARY SYSTEM AT 1200° C. Sheldon Paul Rideout and Paul A. Beck, University of Notre Dame. April 1952. 81p. diagrs., photos., 20 tabs. (NACA TN 2683)

A survey was made of portions of the chromium-cobalt-nickel-molybdenum quaternary system at 1200° C by means of microscopic and X-ray diffraction studies. Since the face-centered cubic (alpha) solid solutions form the matrix of almost all practically useful high-temperature alloys, the solid solubility limits of the quaternary alpha phase were determined up to 20 percent molybdenum. The component cobalt-nickel-molybdenum, chromium-cobalt-molybdenum, and chromium-nickel-molybdenum ternary systems were also studied. The survey of these systems was confined to the determination of the boundaries of the face-centered cubic (alpha) solid solutions and of the phases coexisting with alpha at 1200° C.

NACA TN 2688

THREE-DIMENSIONAL SUPERSONIC NOZZLES AND INLETS OF ARBITRARY EXIT CROSS SECTION. John C. Evvard and Stephen H. Maslen. April 1952. 12p. diagrs. (NACA TN 2688)

A method is presented for obtaining three dimensional unsymmetric supersonic nozzles and inlets from known axisymmetric flows. Streamlines bounding the desired exit shape are traced through the known basic flow solution to give the required unsymmetric wall contours. Several examples are given.

NACA TN 2690

CONDENSATION OF AIR IN SUPERSONIC WIND TUNNELS AND ITS EFFECTS ON FLOW ABOUT MODELS. C. Frederick Hansen and George J. Nothwang. April 1952. 49p. photos., diagrs. (NACA TN 2690)

Condensation of air in supersonic wind tunnels is investigated. Theoretical limits of the threshold of condensation are calculated and compared with experiment. Test results are presented which indicate the effectiveness of water vapor, carbon dioxide, and silica gel as condensation nuclei in supersaturated air. The properties of a partially condensed supersonic air stream are estimated and the effects of condensation phenomena in flow about models are examined.

NACA TN 2693

A THEORY AND METHOD FOR APPLYING INTERFEROMETRY TO THE MEASUREMENT OF CERTAIN TWO-DIMENSIONAL GASEOUS DENSITY FIELDS. Walton L. Howes and Donald R. Buchele. April 1952. 46p. diagrs. (NACA TN 2693)

A theory and method are developed for applying interferometry to the measurement of certain two dimensional gaseous density fields. The theory includes effects of optical refraction upon the observed interference pattern. Expressions for the relative density difference and optical distortion corresponding to an observed interference-fringe shift are derived in exact form and then in the form of power series approximations. An evaluation procedure is outlined and applied in the determination of the density field in a boundary layer formed by supersonic air flow along a flat plate.

NACA TN 2696

A FUNDAMENTAL STUDY OF THE MECHANISM BY WHICH HYDROGEN ENTERS METALS DURING CHEMICAL AND ELECTROCHEMICAL PROCESSING. L. D. McGraw, C. A. Snavely, H. L. Moore, P. T. Woodberry and C. L. Faust, Battelle Memorial Institute. April 1952. ii, 43p. photos., diagr., 6 tabs. (NACA TN 2696)

Through the correlation of several known methods of controlling entry and exit of hydrogen in steel with the known chemical behavior of atomic and molecular hydrogen suitable reagents were found which increase or, for the first time, significantly decrease hydrogen permeability and embrittlement of steels during cathodic pickling and plating operations. This succesful correlation was an important step toward arriving at the mechanism of hydrogen entry into steel. It is proposed that entry is through the direct formation of metal hydrides (intermetallic compounds) or solid solutions of hydrogen in metal at the instant of hydrogen discharge and that exit is the decomposition of metal hydrides or of solid solutions of hydrogen in metal.

NACA TN 2701

A SURVEY OF THE AIRCRAFT-NOISE PROBLEM WITH SPECIAL REFERENCE TO ITS PHYSICAL ASPECTS. Harvey H. Hubbard. May 1952. 41p. diagrs., photos. (NACA TN 2701)

This paper presents brief discussions on three general phases of the aircraft-noise problem. The effects of noise are discussed as a background for the reader and as a basis for discussion of the other material. A description of the physical characteristics of aircraft noise and some ways of protection from noise are also included, along with a limited bibliography of research work applying to the aircraft-noise problem.

NACA RM E52B20

INTERNAL-FILM-COOLING EXPERIMENTS WITH 2- AND 4-INCH SMOOTH-SURFACE TUBES AND GAS TEMPERATURES TO 2000° F. George R. Kinney. April 1952. 27p. diagrs., 2 tabs. (NACA RM E52B20)

An experimental investigation of internal-liquid-film cooling was conducted in 2- and 4-inch-diameter smooth-surface tubes with hot air flows at 800° to 2000° F and Reynolds numbers from 220,000 to 1,100,000. The coolant was water at flows of 0.8 to 12 percent of air flow. Greater cooling effectiveness was obtained than in a previous investigation with a rough-surface tube. When coolant flows were large enough, film disturbances occurred which reduced cooling effectiveness in the same manner in both 2- and 4-inch tubes. All data were generalized by means of heat transfer correlation and data obtained over a range of coolant flows in a form which facilitates the estimation of the flow of film coolant required to cool a length of tube when the temperature and flow of hot gases are known.

CONTRIBUTION TO THE WING THEORY FOR SLIGHTLY INHOMOGENEOUS PARALLEL FLOW. (Beitrag zur Theorie des Tragflügels in schwach inhomogener Parallelströmung). F. Vandrey. March 1952. 12p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 20, no. 3, June 1940, p. 148-152).

Calculation of lift distribution of a wing in a flow with a velocity varying from point to point is traced back to calculation of the lift distribution of a wing of equal chord distribution with an additional twist in a homogeneous parallel flow. The twist is determined from the condition of equivalent pressure on both sides of a surface of constant basic velocity. Presupposition for applicability of the method is the condition that the velocity of the basic flow does not vary greatly in the direction normal to the wind.

N-12159*

THE PROBLEM OF FLOW AROUND A BODY IN INCOMPRESSIBLE POTENTIAL FLOWS. PART II. (Das Umströmungsproblem bei inkompressiblen Potentialströmungen). F. Riegels. April 1952. 31p. diagrs., 10 tabs. (Trans. from Ingenieur-Archiv, v. 17, no. 1-2, 1949, p. 94-106).

For bodies of moderate thickness and camber but otherwise arbitrary shape, a theory is developed which permits determination of the flow velocity, the force, and the moment with the aid of source and vortex distributions on a straight-line segment of the length of the largest chord of the body.

RECIPROCITY RELATIONS IN AERODYNAMICS. Max. A. Heaslet and John R. Spreiter. May 1952. 38p. diagrs. (NACA TN 2700)

Reserve-flow theorems in aerodynamics are shown to be based on the same general concepts involved in many reciprocity theorems in the physical sciences. Reciprocal theorems for both steady and unsteady motion are found as a logical consequence of this approach. No restrictions on wing plan form or flight Mach number are made beyond those required in linearized compressible-flow analysis. A number of examples are listed, including general integral theorems for lifting, rolling, and pitching wings and for wings in nonuniform downwash fields. Correspondence is also established between the build-up of circulation with time of a wing starting impulsively from rest and the build-up of lift of the same wing moving in the reverse direction into a sharp-edge gust.

EXPERIMENTS TO DETERMINE NEIGHBORHOOD REACTIONS TO LIGHT AIRPLANES WITH AND WITHOUT EXTERNAL NOISE REDUCTION. Fred S. Elwell, Aeronautical Research Foundation. May 1952. 75p. diagrs., maps, photos., 12 tabs. (NACA TN 2728)

Experiments to determine neighborhood reactions to the noise of light airplanes with and without noise-reduction equipment were conducted at a number of sites which might be convenient locations for landing strips within the metropolitan area of Boston, Mass. Two standard airplanes and two airplanes modified by reduction gears, four-bladed propellers, and engine exhaust silencers were used. Flights were made close to residential properties of varying income levels, population densities, and proximity to trade centers in order to determine whether the degree of noise reduction previously found to be aerodynamically and structurally practicable produced a significant reduction in neighborhood objections to such aircraft operations.

THE EFFECT OF INDUCED VELOCITY VARIATION ON HELICOPTER ROTOR DAMPING IN PITCH OR ROLL. G. J. Sissingh. November 1951. 16p. diagrs. (RAE Tech. Note Aero 2132)

A continuation of NACA TN 2136 by Amer on the aerodynamic damping of a rotor with centrally arranged flapping hinges in a steady pitching or rolling motion. Considers the effect of variation in induced velocity due to changes in distribution of thrust around the rotor disk. Results agree favorably with flight results given in Amer's report. The rotor damping primarily depends on two quantities: (1) the ratio of collective pitch to the thrust coefficient ÷ solidity ratio, and (2) the tip-speed ratio x rotor angle of attack ÷ collective pitch.

THE MAGNETIC PROPERTIES OF SOME DUCTILE OR MACHINABLE PERMANENT MAGNET ALLOYS. E. C. Railton. November 1951. 10p. diagr., tab. (RAE Tech. Note EL. 29)

The magnetic properties of certain Cu-Ni-Fe and Co-Fe-V alloys have been measured. The alloys are respectively ductile after heat treatment and machinable before heat treatment, and may have application as permanent magnets in aircraft electrical instruments. The Cu-Ni-Fe alloy had magnetic properties that approached those sought. The Co-Fe-V alloy began to approach published claims for it but is, in general, less useful.

HELICOPTER BEHAVIOUR IN THE VORTEX RING CONDITIONS. Wm. Stewart. November 1951. 15p. diagrs., tab. (RAE Tech. Note Aero 2131)

A region of roughness, associated with the air flow conditions of the vortex-ring state, occurs when a helicopter is operating in vertical or near vertical descents in the range of about 500 and 1500 ft/min. The turbulent circulating air and the rapid changes in local velocities in this flow pattern can cause serious helicopter handling difficulties. This could cause concern in a slow steep approach, particularly under instrument flying conditions. This report describes flight experience in the vortex-ring conditions with the Sikorsky R-4B, R-6 and S-51, Bell 47 and the Bristol 171 helicopters.

SOME CURVES FOR USE IN CALCULATIONS OF THE PERFORMANCE OF CONICAL CENTREBODY INTAKES AT SUPERSONIC SPEEDS AND AT FULL MASS FLOW. L. E. Fraenkel. December 1951. 33p. diagrs., 2 tabs. (RAE Tech. Note Aero 2135)

Presents curves of a number of parameters which frequently occur in calculations of the performance of conical centerbody intakes at supersonic speeds and full mass flow. These parameters follow directly from the theoretical supersonic flow past cones. Semicone angles of 15°, 20°, 22.5°, 25°, and 30° are considered, and the range of free stream Mach number is approximately 1.3 to 3.0.

N-14710*

National Gas Turbine Establishment (Gt. Brit.)
A PHENOMENOLOGICAL THEORY OF UNIAXIAL DEFORMATION. A. Graham. December 1951. 30p. diagrs. (NGTE R. 94)

Previous theories are briefly reviewed and a form of the Nutting equation in which the constants are expressed as functions of temperature is shown to avoid some of the difficulties of theories which assume existence of an equation of state in terms of stress, strain, straining rate, and temperature. A linear theory is developed in which deformation is represented as a Boltzmann superposition of increments of creep due to increments of load. The resulting superposition integral is not an equation of state in the above-mentioned terms. It directly predicts behavior under various conditions of loading. The theory is extended to cover temperature and apparent changes in material constants.

CURRENT NACA REPORTS

NACA Rept. 1014

STUDY OF EFFECTS OF SWEEP ON THE FLUTTER OF CANTILEVER WINGS. J. G. Barmby, H. J. Cunningham and I. E. Garrick. 1951. ii, 25p. diagrs., photo., 7 tabs. (NACA Rept. 1014. Formerly TN 2121; RM L8H30)

An experimental and analytical investigation of the flutter of uniform, cantilever, sweptback wings is reported. The experiments employed group of wings swept back by rotating and by shearing. The angle of sweep ranged from 0° to 60° and the Mach numbers extended to approximately 0.85. Comparison with experiment indicates that the analysis developed in the present paper is satisfactory, at least for nearly uniform cantilever wings of moderate length-chord ratios.

NACA Rept. 1018

A THEORETICAL ANALYSIS OF THE EFFECT OF TIME LAG IN AN AUTOMATIC STABILIZATION SYSTEM ON THE LATERAL OSCILLATORY STABILITY OF AN AIRPLANE. Leonard Sternfield and Ordway B. Gates, Jr. 1951. ii, 12p. diagrs. (NACA Rept. 1018. Formerly TN 2005)

A method is presented for determining the effect of time lag in an automatic stabilization system on the lateral oscillatory stability of an airplane. The method is applied to a typical present-day airplane equipped with an automatic pilot sensitive to yawing acceleration and geared to the rudder so that rudder control is applied in proportion to the yawing acceleration.

NACA Rept. 1027

BUCKLING OF THIN-WALLED CYLINDER UNDER AXIAL COMPRESSION AND INTERNAL PRESSURE. Hsu Lo, Harold Crate and Edward B. Schwartz. 1951. 9p. diagrs. (NACA Rept. 1027. Formerly TN 2021)

An investigation was made of a thin-walled cylinder under axial compression and various internal pressures to study the effect of the internal pressure on the compressive buckling stress of the cylinder. A theoretical analysis based on a large-deflection theory was also made. The theoretically predicted increase of compressive buckling stress due to internal pressure agrees fairly well with the experimental results.

NACA Rept. 1031

A STUDY OF THE USE OF EXPERIMENTAL STABILITY DERIVATIVES IN THE CALCULATION OF THE LATERAL DISTURBED MOTIONS OF A SWEPT-WING AIRPLANE AND COMPARISON WITH FLIGHT RESULTS. John D. Bird and Byron M. Jaquet. 1951. ii, 25p. diagrs., photos., 4 tabs. (NACA Rept. 1031. Formerly TN 2013)

Experimentally determined lateral-stability derivatives of a swept-wing airplane are presented to show effects of slots, flaps, propeller, and ventral fins and are used in calculations of a number of lateral disturbed motions. The calculated motions are compared with those obtained in flight tests to determine the applicability of the experimental stability derivatives. The effects of nonlinearity of some of the aerodynamic forces with sideslip are shown by a few supplemental calculations.

NACA Rept. 1036

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF VISCOSITY ON THE DRAG AND BASE PRESSURE OF BODIES OF REVOLUTION AT A MACH NUMBER OF 1.5. Dean R. Chapman and Edward W. Perkins. 1951. ii, 24p. photos., diagrs. (NACA Rept. 1036. Formerly NACA RM A7A31a)

Models were tested to evaluate effects of Reynolds number for both laminar and turbulent boundary layers. Principal geometric variables investigated were afterbody shape and length-diameter ratio. Force tests and base-pressure measurements were made. Schlieren photographs were used to analyze the effects of viscosity on flow separation and shock-wave configuration and to verify the condition of the boundary layer as deduced from the force tests. The results are discussed and compared with theoretical calculations.

NACA Rept. 1039

ON THE PARTICULAR INTEGRALS OF THE PRANDTL-BUSEMANN ITERATION EQUATIONS FOR THE FLOW OF A COMPRESSIBLE FLUID. Carl Kaplan. 1951. ii, 6p. (NACA Rept. 1039. Formerly TN 2159)

The particular integrals of the second-order and third-order Prandtl-Busemann iteration equations for the flow of a compressible fluid are obtained by means of the method in which the complex conjugate variables z and $\bar{z}$ are utilized as the independent variables of the analysis. The assumption is made that the Prandtl-Glauert solution of the linearized or first-order iteration equation for the two-dimensional

flow of a compressible fluid is known. The forms of the particular integrals, derived for subsonic flow, are readily adapted to supersonic flows with only a change in sign of one of the parameters of the problem.

NACA TN 2489

AERODYNAMIC CHARACTERISTICS OF A REFINED DEEP-STEP PLANING-TAIL FLYING-BOAT HULL WITH VARIOUS FOREBODY AND AFTERBODY SHAPES. John M. Riebe and Rodger L. Naeseth. June 1952. 48p. photos., diagrs., 8 tabs. (NACA TN 2489. Formerly RM L8F01)

An investigation was made in the Langley 300-mph 7- by 10-foot tunnel to determine the aerodynamic characteristics of a refined deep-step planing-tail hull with various forebody and afterbody shapes and, for comparison, a streamline body simulating the fuselage of a modern transport airplane. The results of the tests indicated that the configurations incorporating a forebody with a length-beam ratio of 7 had lower minimum drag coefficients than the configurations incorporating a forebody with length-beam ratio of 5. The lowest minimum drag coefficients, which were considerably less than that of a conventional hull and slightly less than that of a streamline body, were obtained on the length-beam-ratio-7 forebody, alone and with round center boom. Drag coefficients and longitudinal- and lateral-stability parameters presented include the interference of a 21-percent-thick support wing.

NACA TN 2641

A VECTOR STUDY OF LINEARIZED SUPERSONIC FLOW APPLICATIONS TO NONPLANAR PROBLEMS. John C. Martin. June 1952. 81p. diagrs., tab. (NACA TN 2641)

A vector study of the partial-differential equation of steady linearized supersonic flow is presented. General expressions are derived which relate the velocity potential in the stream to the conditions on the disturbing surfaces. Problems concerning nonplanar systems are investigated, and methods are derived for the solution of some simple problems. The damping in roll is found for rolling tails consisting of four, six, and eight rectangular fins.

NACA TN 2657

SOME EFFECTS OF FREQUENCY ON THE CONTRIBUTION OF A VERTICAL TAIL TO THE FREE AERODYNAMIC DAMPING OF A MODEL OSCILLATING IN YAW. John D. Bird, Lewis R. Fisher and Sadie M. Hubbard. April 1952. 39p. diagrs., photo., tab. (NACA TN 2657)

The damping in yaw and the directional stability of a model freely oscillating in yaw were measured tail-off and tail-on and compared with the values obtained by theoretical consideration of the unsteady lift associated with an oscillating vertical tail. A range of low frequencies comparable to those of the lateral motions of airplanes was covered. The analysis includes the effects of vertical-tail aspect ratio and the two-dimensional effects of compressibility.

NACA TN 2670

HIGH-SPEED SUBSONIC CHARACTERISTICS OF 16 NACA 6-SERIES AIRFOIL SECTIONS. Milton D. Van Dyke. March 1952. 65p. diagrs., tab. (NACA TN 2670. Formerly RM A7J23)

High-speed subsonic characteristics have been measured for NACA 63-, 64-, 65-, and 66-series airfoil sections having thickness ratios of 6, 8, 10, and 12 percent and an ideal lift coefficient of 0.2. For given thickness ratio, airfoil sections with minimum pressure near 40-percent chord exhibit the best overall aerodynamic characteristics. For even the thinnest sections, good high-speed performance is maintained over a wide range of lift coefficient.

NACA TN 2672

THEORETICAL AUGMENTATION OF TURBINE-PROPELLER ENGINE BY COMPRESSOR-INLET WATER INJECTION, TAIL-PIPE BURNING, AND THEIR COMBINATION. Reece V. Hensley. March 1952. 43p. diagrs. (NACA TN 2672)

A theoretical evaluation of the performance of turbine propeller engines with augmentation by water injection, tail-pipe burning, and by their combination was made. The investigation covered the flight conditions for which each method of augmentation was most suitable for Mach numbers up to 1.1 and altitudes up to 35,000 feet. The variation in augmentation with varying compressor and turbine efficiencies, compressor pressure ratio, and turbine-inlet temperature was calculated. The augmentation with varying ambient temperature and relative humidity was determined and the dependence of the augmentation on the completeness of evaporation during compression was investigated.

NACA TN 2676

SUMMARY OF STALL-WARNING DEVICES. John A. Zalovcik. May 1952. 15p. diagrs. (NACA TN 2676)

Principles involved in the operation of stall-warning devices are described and conditions under which difficulty may be experienced are pointed out. Some specific examples of stall-warning devices are illustrated and described.

NACA TN 2689

EFFECT OF HIGH-LIFT DEVICES ON THE LOW-SPEED STATIC LATERAL AND YAWING STABILITY CHARACTERISTICS OF AN UNTAPERED 45° SWEPT-BACK WING. Jacob H. Lichtenstein. May 1952. 20p. diagrs., photo. (NACA TN 2689. Formerly RM L8G20)

Results of a low-speed wind-tunnel investigation to determine the effect of high-lift devices on the static lateral stability derivatives and the yawing derivatives of an untapered 45° sweptback wing are presented. The tests were made in the curved-flow test section of the Langley stability tunnel at a Reynolds number of 1.1×10^6.

NACA TN 2692

ON THE FORM OF THE TURBULENT SKIN-FRICTION LAW AND ITS EXTENSION TO COMPRESSIBLE FLOWS. Coleman duP Donaldson. May 1952. 19p. diagrs. (NACA TN 2692)

A derivation of the form of the incompressible turbulent skin-friction law for an insulated flat plate is made in such a way that it may be extended to compressible flows. The ratio of compressible to incompressible skin friction is obtained, and the results are shown to be in good agreement with existing experimental results.

NACA TN 2695

MIGRATION OF COBALT DURING FIRING OF GROUND-COAT ENAMELS ON IRON. William N. Harrison, Joseph C. Richmond, Joseph W. Pitts and Stanley G. Benner, National Bureau of Standards. June 1952. 28p. photos., 5 tabs. (NACA TN 2695)

A typical porcelain-enamel ground coat containing a small amount of radioactive cobalt as oxide was prepared, applied to sandblasted enameling-iron blanks, and fired under conditions selected to give underfired, normally fired, and overfired coatings. Examination of these specimens revealed that a cobalt-bearing metallic deposit had been formed at the enamel-metal interface during firing, and that the enamel layer was depleted in cobalt oxide near the interface. The amounts of such deposit and depletion were found to vary directly with the severity of the firing treatment. The amount of metallic deposit was extremely small, on the order of 0.01 micron thick if computed as a continuous layer of metallic cobalt in the case of the normally fired specimens.

NACA TN 2697

METHOD AND GRAPHS FOR THE EVALUATION OF AIR-INDUCTION SYSTEMS. George B. Brajnikoff. April 1952. 41p. diagrs., tab. (NACA TN 2697)

Graphs that allow rapid evaluation of air-induction systems from considerations of their aerodynamic parameters in combination with power-plant characteristics are presented for the supersonic Mach numbers up to 3.0. Restrictions imposed by the engine characteristics on the use of a fixed-size air inlet are discussed and illustrated by means of sample solutions. The relation between the engine characteristics, flight conditions, inlet characteristics, and inlet area for optimum performance is given.

NACA TN 2698

THEORETICAL ANALYSIS OF HYDRODYNAMIC IMPACT OF A PRISMATIC FLOAT HAVING FREEDOM IN TRIM. Robert W. Miller. June 1952. 31p. diagrs., 2 tabs. (NACA TN 2698)

The paper presents the derivation and a method for solution of equations taking into account the effects of freedom in trim on the loads, moments, and motions of a prismatic, V-bottom float forebody during hydrodynamic impact. Comparisons of solutions of the equations with fixed-trim solutions and with some experimental data are presented and indicate that the solutions are reasonable and consistent with both the experimental data and with general experience.

NACA TN 2699

CALCULATION OF LIFT AND PITCHING MOMENTS DUE TO ANGLE OF ATTACK AND STEADY PITCHING VELOCITY AT SUPERSONIC SPEEDS FOR THIN SWEPTBACK TAPERED WINGS WITH STREAMWISE TIPS AND SUPERSONIC LEADING AND TRAILING EDGES. John C. Martin, Kenneth Margolis and Isabella Jeffreys. June 1952. 116p. diagrs., 9 tabs. (NACA TN 2699)

On the basis of linearized supersonic-flow theory formulas for the stability derivatives C_{m_α}, C_{L_q}, and C_{m_q} were derived for a series of thin sweptback tapered wings with streamwise tips and supersonic leading and trailing edges. The results of the analysis are presented as a series of design charts. Some illustrative variations of the derivatives and of the chordwise center-of-pressure location with the various wing design parameters are also included.

NACA TN 2702

AN APPROXIMATE METHOD OF DETERMINING THE SUBSONIC FLOW IN AN ARBITRARY STREAM FILAMENT OF REVOLUTION CUT BY ARBITRARY TURBOMACHINE BLADES. Chung-Hua Wu, Curtis A. Brown and Vasily D. Prian. June 1952. 46p. diagrs., 4 tabs. (NACA TN 2702)

A method is presented to obtain a relatively quick approximate solution of the detailed subsonic flow of a nonviscous fluid past arbitrary turbomachine blade sections lying on an arbitrary surface of revolution. Calculation is first made for the flow along a particular streamline about midway between two adjacent blades. Extension of the flow from this streamline to the blade surfaces is then made by the use of a Taylor's series, and a method is provided to correct the solution to fit the given blade shape and operating conditions. The method is illustrated with examples of compressible flow in a turbine cascade and a centrifugal compressor. Three terms of the Taylor's series are found to give sufficient accuracy. Sufficient convergence is obtained for the turbine cascade after two cycles of computation and for the centrifugal compressor after four cycles of compu-

tation. (Each cycle of computation takes 16 hours.) The detailed flow distribution obtained compares very well with an available numerical solution and experimental data.

NACA TN 2703

ELECTRICAL TECHNIQUES FOR COMPENSATION OF THERMAL TIME LAG OF THERMOCOUPLES AND RESISTANCE THERMOMETER ELEMENTS. Charles E. Shepard and Isidore Warshawsky. May 1952. ii, 85p. diagrs., photos., 9 tabs. (NACA TN 2703)

Basic electrical networks are described that compensate for the thermal time lag of thermocouple and resistance thermometer elements. For a given set of operating conditions, networks requiring no amplifiers can provide a thirtyfold reduction in effective time lag. This improvement is obtained without attenuation of the voltage signal, but does result in a large reduction in the amount of electric power available because of an increase in the output impedance of the network. Networks using commercially available amplifiers can provide a thousandfold reduction in the effective time lag without attenuation of the alternating voltage signal or of the available electric power, but the improvement is often obtained at the expense of loss of the zero-frequency signal. The completeness of compensation is limited by the extent of off-design operation required.

NACA TN 2704

FATIGUE STRENGTHS OF 14S-T4 ALUMINUM ALLOY SUBJECTED TO BIAXIAL TENSILE STRESSES. Joseph Marin and W. P. Hughes, Pennsylvania State College. June 1952. 24p. photos., diagrs., 5 tabs. (NACA TN 2704)

The purpose of this investigation was to determine the influence of biaxial tensile stresses on the fatigue strength of a 14S-T4 aluminum alloy when subjected to various ratios of biaxial stresses. The effect upon the fatigue strength of varying the ratios of biaxial stresses was studied. The biaxial fatigue stresses were produced by applying simultaneously a pulsating internal pressure and a fluctuating axial tensile load to a thin-walled tubular specimen. The maximum and minimum values of the longitudinal and circumferential stresses were kept in phase by adjusting the testing machine. The fatigue strengths and S-N diagrams were obtained up to about 10^7 cycles for four principal stress ratios.

NACA TN 2705

THEORY OF SUPERSONIC POTENTIAL FLOW IN TURBOMACHINES. Robert H. Wasserman. June 1952. 44p. diagrs. (NACA TN 2705)

A general method for solving supersonic potential flow problems for stationary or rotating coordinate systems is presented. The principal attributes of the method are: It can handle flows which cannot be treated as two-dimensional, and a sound theoretical basis gives assurance of its validity for a class of boundary-value problems. An application to the design of a compressor rotor is made.

NACA TN 2706

EFFECT OF CHANGING PASSAGE CONFIGURATION ON INTERNAL-FLOW CHARACTERISTICS OF A 48-INCH CENTRIFUGAL COMPRESSOR. I - CHANGE IN BLADE SHAPE. Donald J. Michel, John Mizisin and Vasily D. Prian. May 1952. 40p. diagrs., photo., tab. (NACA TN 2706)

The passage contour of a 48-inch centrifugal impeller was modified by changing the shape of the blades. A comparison of the internal-flow characteristics was made of the original and modified passage contours at the design flow rate. In addition, the internal-flow characteristics of the modified passage are presented and analyzed over the entire flow range from maximum flow to surge at a corrected impeller tip speed of 700 feet per second. At design flow, the modified impeller, which had lesser deceleration rates along the blade surfaces, showed a general improvement in efficiency throughout the passage over that of the original impeller. At high weight flows (negative angles of attack), there were large separation losses at the inlet because of the shape of the leading edge; at low flow rates (positive angle of attack), the separation losses were not as great. The low-efficiency regions in the passage generally occurred near the flow surfaces with decelerating flow, except along the driving face where most boundary-layer build-up by adverse velocity gradients was probably eliminated by secondary flows or bleeding through the clearance space.

NACA TN 2707

ANALOGUE-COMPUTER SIMULATION OF AN AUTOPILOT SERVO SYSTEM HAVING NONLINEAR RESPONSE CHARACTERISTICS. Arthur L. Jones and John S. White. June 1952. 30p. diagrs. (NACA TN 2707)

The nonlinear response characteristics of an electrohydraulic servo system were successfully simulated using an electronic analogue computer (differential analyzer). In obtaining a satisfactory simulation it was necessary not only to take into account an easily recognized nonlinear amplifier response but also the accumulative effect of some time lags of the servo system.

NACA TN 2708

COMPARISON OF THREE MULTICYLINDER ICING METERS AND CRITIQUE OF MULTICYLINDER METHOD. Wallace E. Howell, Mount Washington Observatory. June 1952. 40p. diagrs., photos., 6 tabs. (NACA TN 2708)

Three multicylinder icing meters, fundamentally similar but differing from each other in important

deisgn details, were compared in use at the Mount Washington Observatory. Comparison of relative effectiveness of the instruments, evaluation of observational errors, determination of the effects of detailed design differences, and recommendations for further improvements of design are presented. An evaluation of the multicylinder method, concerned with the validity of the theoretical basis and the degree to which the instruments and the technique of their use permit accurate determinations of the physical measurements involved, is also included.

NACA TN 2709

FATIGUE AND STATIC TESTS OF FLUSH-RIVETED JOINTS. Darnley M. Howard and Frank C. Smith, National Bureau of Standards. June 1952. 38p. photos., diagrs., 3 tabs. (NACA TN 2709)

Fatigue and static tests were made of 1/8-inch diameter A17S-T3 100° countersunk-head rivets in lap and butt joints. Both machine-countersunk and dimpled holes were used. The sheet materials were 0.032-inch-thick bare and alclad 24S-T3 and 75S-T6 aluminum alloys and 0.064-inch-thick alclad 75S-T6 alloy. From the results no satisfactory single relation between static properties and fatigue life covering the four materials could be found.

NACA TN 2710

DIFFUSION OF HEAT FROM A LINE SOURCE IN ISOTROPIC TURBULENCE. Mahinder S. Uberoi and Stanley Corrsin, Johns Hopkins University. June 1952. 90p. diagrs., photos., tab. (NACA TN 2710)

An experimental and analytical study has been made of some features of the turbulent heat diffusion behind a line heated wire stretched perpendicular to a flowing isotropic turbulence. The mean temperature distributions have been measured with systematic variations in wind speed, size of turbulence producing grid, and downstream location of heat source. The nature of the temperature fluctuation field has been studied. A comparison of Lagrangian and Eulerian analyses for diffusion in a nondecaying turbulence yields an expression for turbulent-heat-transfer coefficient in terms of turbulence velocity and a Lagrangian "scale." A convenient form has been deduced for the criterion of interchangeability of instantaneous space and time derivatives in a flowing turbulence.

NACA TN 2712

FLOW CHARACTERISTICS OVER A LIFTING WEDGE OF FINITE ASPECT RATIO WITH ATTACHED AND DETACHED SHOCK WAVES AT A MACH NUMBER OF 1.40. John H. Hilton, Jr. June 1952. 21p. diagrs., photos. (NACA TN 2712)

A series of schlieren photographs and pressure distributions obtained in the Langley 4- by 4-foot supersonic tunnel are presented to illustrate the general characteristics of supersonic flow over a wedge under conditions of attached and detached shock. The pressure distributions and aerodynamic coefficients are compared with shock-expansion theory.

NACA TN 2713

EFFECT OF COMPRESSOR-OUTLET AIR BLEED ON PERFORMANCE OF A CENTRIFUGAL-FLOW TURBOJET ENGINE WITH A CONSTANT-AREA JET NOZZLE. Sidney C. Huntley. June 1952. 20p. diagrs. (NACA TN 2713)

The effect of compressor-outlet air bleed on the performance of a centrifugal-flow turbojet engine is presented. The cost of compressor-outlet air bleed in terms of the increase in net-thrust specific fuel consumption was about 2 percent for each percent of air bleed for constant engine speed, maximum net thrust, or constant net-thrust operation. When maximum net-thrust operation with air bleed occurred at a constant tail-pipe temperature, the maximum net thrust decreased at a rate of about 2.5 percent for each percent of air bleed, while the loss in net thrust with air bleed at constant engine speed was only about 0.5 percent for each percent of air bleed.

NACA TN 2714

NORMAL ACCELERATIONS AND OPERATING CONDITIONS ENCOUNTERED BY A HELICOPTER IN AIR-MAIL OPERATIONS. Almer D. Crim and Marlin E. Hazen. June 1952. 17p. diagrs., photos., 2 tabs. (NACA TN 2714)

An analysis is presented of the normal accelerations and operating conditions encountered by a single-rotor helicopter engaged in air-mail operation in the vicinity of Los Angeles and its suburbs.

NACA TN 2716

EFFECT OF OPEN CIRCULAR HOLES ON TENSILE STRENGTH AND ELONGATION OF SHEET SPECIMENS OF A MAGNESIUM ALLOY. R. S. Barker, Aluminum Company of America. June 1952. 24p. diagrs., 6 tabs. (NACA TN 2716)

The effect of open circular holes on the tensile strength and elongation of sheet specimens of magnesium alloy AM-C52S in both the annealed and the hard-rolled condition was investigated. Tests were made to study the effect of variable ratio of hole diameter to total specimen width and also the effect of spacing and arrangement of the holes. It was found that greater reductions in strength were exhibited by the annealed material but that the hard-rolled material showed the greater reductions in elongation.

NACA TN 2717

EFFECT OF TEMPERATURES FROM -70° TO 600° F ON STRENGTH OF ADHESIVE-BONDED LAP SHEAR SPECIMENS OF CLAD 24S-T3 ALUMINUM ALLOY AND OF COTTON- AND GLASS-FABRIC PLASTIC LAMINATES. H. W. Eickner, W. Z. Olson and R. F. Blomquist, Forest Products Laboratory. June 1952. 26p. diagrs., 6 tabs. (NACA TN 2717)

The performance of 14 commercial adhesives at temperatures from -70° to 600° F was evaluated in lap shear specimens of clad 24S-T3 aluminum alloy to itself and that of 7 commercial adhesives at -70° to 250° F in lap joints of cotton-fabric-phenolic laminate to itself, of glass-fabric-polyester laminate to itself, and in joints of each of these laminates to clad aluminum. One hot-setting tape adhesive was found to be consistently superior to all others in lap-joint specimens of aluminum tested at 450° F after 192 hours at 450° F. The best of the commercial adhesives evaluated at -70° to 250° F in lap shear specimens of plastic laminates bonded to themselves and to aluminum had only fair resistance to stressing immediately upon reaching 250° F. The adhesives generally performed adequately in the various joints at -70° F.

NACA TN 2718

TWO-DIMENSIONAL STEADY NONVISCOUS AND VISCOUS COMPRESSIBLE FLOW THROUGH A SYSTEM OF EQUIDISTANT BLADES. Hans J. Reissner, Leonard Meyerhoff and Martin Bloom, Polytechnic Institute of Brooklyn. June 1952. 48p. diagrs., 4 tabs. (NACA TN 2718)

The problem of two-dimensional flow of a compressible nonviscous fluid through blade systems of equidistant spacing, of identical shape, and of straight-line arrangement of position is analyzed. Viscous flow through a grid system of equidistant, narrowly spaced blades is treated in an appendix.

NACA TN 2719

INVESTIGATION OF STATISTICAL NATURE OF FATIGUE PROPERTIES. E. Epremian and R. F. Mehl, Carnegie Institute of Technology. June 1952. ii, 119p. diagrs., photos., tab. (NACA TN 2719)

Extensive fatigue tests were made on annealed Armco iron and plain carbon and alloy steels heat-treated to different strengths and microstructures. Statistics of fatigue-fracture curves and endurance limits were determined from the experimental data obtained and, for various other materials, from a survey of literature. The results were analyzed to show the relative effects of various metallurgical factors on the statistical nature of fatigue properties. Other phases of the problem studied include: dependence of statistical variation in fatigue life on stress level in the fracture range, statistics for location of crack initiation, size effect, understressing effect, and the form and method of plotting the S-N diagram.

NACA TN 2721

INITIAL RESULTS OF INSTRUMENT-FLYING TRIALS CONDUCTED IN A SINGLE-ROTOR HELICOPTER. Almer D. Crim, John P. Reeder and James B. Whitten. June 1952. 16p. diagrs., photos. (NACA TN 2721)

Instrument-flying trials have been conducted in a single-rotor helicopter to determine the adequacy of existing longitudinal flying-qualities requirements under instrument conditions. In addition, lateral-directional characteristics were examined. The suitability, for helicopter use, of standard airplane instruments was also investigated.

NACA TN 2722

DISPLACEMENT EFFECT OF A THREE-DIMENSIONAL BOUNDARY LAYER. Franklin K. Moore. June 1952. 15p. diagrs. (NACA TN 2722)

A method is described for determining the "displacement surface" of a known three-dimensional boundary-layer flow in terms of the mass-flow defects associated with the profiles of the two velocity components parallel to the surface. The displacement surface height is shown to differ, in general, from that associated with the resultant mass-flow defect, even at stagnation points of the secondary flow. Numerical values are found for the known three-dimensional boundary-layer flow about a cone at a small angle of attack to a supersonic stream.

NACA TN 2723

USE OF THE BOUNDARY LAYER OF A CONE TO MEASURE SUPERSONIC FLOW INCLINATION. Franklin K. Moore. June 1952. 21p. diagrs. (NACA TN 2723)

An instrument is suggested for the measurement of supersonic flow inclination, taking advantage of the effect of angle of attack on the meridional velocity profile of the boundary layer on a cone. This effect of angle of attack may be measured by the difference of total pressure recorded by two probes pointing toward the apex and located in the plane of symmetry of the flow.

NACA TN 2725

INTERACTION OF OBLIQUE SHOCK WAVES WITH REGIONS OF VARIABLE PRESSURE, ENTROPY, AND ENERGY. W. E. Moeckel. June 1952. 34p. diagrs. (NACA TN 2725)

Equations are developed for computing the propagation of oblique shock waves through regions in which pressure, energy, or entropy are continuously variable. For the special cases of supersonic shear flow and Prandtl-Meyer flow, charts are given of shock angle as function of Mach number for any initial-strength wave. A sufficient condition for the avoidance of upstream effects due to shock propagation is found. A wave-interaction procedure for determining supersonic portions of the flow downstream of the shock is described, and an approximate method for dealing with imbedded subsonic regions is proposed.

NACA TN 2729

AN ANALYSIS OF SUPERSONIC FLOW IN THE REGION OF THE LEADING EDGE OF CURVED AIRFOILS, INCLUDING CHARTS FOR DETERMINING SURFACE-PRESSURE GRADIENT AND SHOCK-WAVE CURVATURE. Samuel Kraus. June 1952. 45p. diagrs., 5 tabs. (NACA TN 2729)

Flow in the region of the leading edge of curved airfoils with attached shock waves is investigated. Tables and charts are presented for determining the surface-pressure gradient and shock-wave curvature in supersonic flow of an ideal diatomic gas. The results cover a range of Mach numbers from 1.5 to infinite and deflection angles from zero up to those approaching shock detachment. Calculations of surface-pressure gradient and shock-wave curvature are also made for curved airfoils in supersonic flow of a calorically imperfect, diatomic gas. An approximate procedure for determining the flow field a short distance downstream of the leading edge is also presented.

NACA TN 2731

INFLUENCE OF STRUCTURE ON PROPERTIES OF SINTERED CHROMIUM CARBIDE. H. J. Hamjian and W. G. Lidman. June 1952. 21p. diagrs., photos., 5 tabs. (NACA TN 2731)

An investigation was conducted to study the influence of structural variations on the properties of chromium carbide sintered under pressure. The results show that the room-temperature strength and hardness are influenced by the stages of sintering, which are defined by grain size and by the number, size, location, and shape of pores. The extent to which sintering has progressed during the second stage when densification occurs and the sintering conditions which will yield optimum room-temperature strength can be determined from hardness. It was found that coarse-grained structures are detrimental to room temperature strength. On the basis of limited data, coarse-grained structures may not be detrimental at elevated temperatures.

NACA RM 52D03

DESIGN OF APPARATUS FOR DETERMINING HEAT TRANSFER AND FRICTIONAL PRESSURE DROP OF NITRIC ACID FLOWING THROUGH A HEATED TUBE. Bruce A. Reese and Robert W. Graham, Purdue University. June 1952. 61p. diagrs., photos., tab. (NACA RM 52D03)

A design basis is presented for test apparatus to measure heat-transfer and pressure-drop characteristics of white fuming nitric acid under conditions simulating those occurring in a regeneratively cooled rocket engine. The apparatus is designed so that heat-transfer and fluid-friction data can be obtained over the following ranges: inlet pressure to test section, atmospheric to 400 pounds per square inch absolute; mean fluid temperature at entrance to heated test section, -30° to 300° F; heat input to test section, 0.5 to 1.5 Btu per second per square inch; and Reynolds number, 60,000 to 200,000.

NACA RM E52A11

ANALYSIS OF A PNEUMATIC PROBE FOR MEASURING EXHAUST-GAS TEMPERATURES WITH SOME PRELIMINARY EXPERIMENTAL RESULTS. Marvin D. Scadron. May 1952. 26p. diagrs., 4 tabs. (NACA RM E52A11)

A pneumatic probe based on continuity of mass flow through two restrictions separated by a cooling chamber was constructed to measure gas temperature at and beyond the limit of thermocouples. This probe consisted of a subsonic flat-plate orifice for the first restriction and a sonic-flow converging-diverging nozzle for the second restriction. The effect of variation in gas constants on the calibration is examined for common engine-exhaust gases. A high-temperature wind tunnel that allowed calibration of the probe at temperatures up to 2000° R and Mach numbers up to 0.8 is described. Agreement to better than 30° R between pneumatic probe indication and the indication of a rake of radiation-shielded thermocouples indicates that extrapolation of the calibration to higher temperatures is possible with fair accuracy.

NACA RM E52C05

INVESTIGATION OF EFFECTIVE THERMAL CONDUCTIVITIES OF POWDERS. R. G. Deissler and C. S. Eian. June 1952. 44p. diagrs., tab. (NACA RM E52C05)

A simplified analysis was made to determine the effective thermal conductivity of a powder from the fraction of space occupied by the gas and the conductivities of the solid and the gas which make up the powder. In order to check the analysis and to obtain data of current technical interest, tests were conducted to determine the conductivity of magnesium oxide powder in various gases at temperatures between 200° and 800° F. Good agreement was obtained between analytical and experimental results. The effects of some of the factors neglected in the simplified analysis such as the bending of heat-flow lines and the irregularity of the arrangement of the particles were investigated and discussed.

NACA RM E52D03

PRELIMINARY SURVEY OF BOUNDARY-LAYER DEVELOPMENT AT A NOMINAL MACH NUMBER OF 5.5. Harold L. Bloom. June 1952. 26p. diagrs., photos. (NACA RM E52D03)

Mean skin-friction coefficients on a flat-plate model, with and without initial roughness, and on a wind tunnel wall were measured at a nominal Mach number of 5.5 over a Reynolds number range from 1×10^6 to 1×10^7, and the results were compared with analytical values. Although evidence of air condensation was obtained in the test section, experimental mean skin-friction coefficients on the tunnel wall and on the flat plate with artificial transition agreed quite well with the analytical results of H. U. Eckert and E. R. Van Driest. Experimental skin-friction coefficients on the plate with natural transition fell between theoreti-

cal laminar values and the analytical turbulent values of Eckert and of Van Driest. Because of the presence of air condensation, the results reported herein must be regarded as tentative.

NACA RM L52A28

NORMAL ACCELERATIONS AND ASSOCIATED OPERATING CONDITIONS ON FOUR TYPES OF COMMERCIAL TRANSPORT AIRPLANES FROM VGH DATA AVAILABLE AS OF SEPTEMBER 1951. Roy Steiner and Doris A. Persh. May 1952. 8p. diagrs., 5 tabs. (NACA RM L52A28)

The NACA VGH time-history records of normal acceleration, airspeed, and altitude of 377, 520, and 118 hours each for 3 four-engine aircraft and 377 hours for a twin-engine aircraft have been evaluated. The summaries of gust loads and the associated operating conditions are presented.

NACA TM 1331

INVESTIGATIONS OF THE BOUNDARY-LAYER CONTROL OF A FULL SCALE SWEPT WING WITH AIR BLED OFF FROM THE TURBOJET. (Recherches sur l'Hypersustentation d'une Aile en Flèche Réelle par Controle de la Couche Limite Utilisant le Prélèvement d'Air sur le Turbo-Réacteur). P. Rebuffet and Ph Poisson-Quinton. April 1952. 43p. diagrs., photos. (NACA TM 1331. Trans. from Recherche Aéronautique, no.14, March-April, 1950, p.39-54)

The various stages of a boundary-layer control study, culminating in the investigation of combined suction and blowing in conjunction with a drooped-nose flap and a form of double-slotted trailing-edge flap on a full-scale 10-percent thick $31^{\circ}\ 20'$ sweptback wing model in the Chalais-Meudon large-scale tunnel, are described. The suction and blowing was accomplished with ejectors fed by bleed-off air from a turbojet engine. A lift coefficient increment of 1.36 was obtained by the use of boundary-layer control.

NACA TM 1332

EXTENSION TO THE CASES OF TWO DIMENSIONAL AND SPHERICALLY SYMMETRIC FLOWS OF TWO PARTICULAR SOLUTIONS TO THE EQUATIONS OF MOTION GOVERNING UNSTEADY FLOW IN A GAS. (Estensione ai Casi di Simmetria Centrale Bi-e Tri-Dimensionale di Due Particolari Soluzioni delle *Equazioni del Moto Gassoso Non Permanente*). Lorenzo Poggi. June 1952. 6p. (NACA TM 1332. Trans. from Onore di Modesto Panetti, November 25, 1950.)

The author previously discovered two interesting particular solutions to the equations of motion describing unsteady flow in a gas confined solely to a one-dimensional duct. These solutions are now extended to cover the more noteworthy cases of central symmetry in two and three dimensions.

NACA TM 1334

THE EFFECT OF HIGH VISCOSITY ON THE FLOW AROUND A CYLINDER AND AROUND A SPHERE. (Der Einfluss grosser Zähigkeit bei der Strömung um den Zylinder und um die Kugel). F. Homann. June 1952. 29p. diagrs., tab. (NACA TM 1334. Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 16, no. 3, June 1936, p. 153-164).

The report records an experimental and theoretical investigation of the influence of high viscosity on the stagnation pressure of flow around cylinders and spheres. For the three-dimensional problem, a differential equation is set up which corresponds to the two-dimensional solution by Heimenz. Theoretical methods are developed for determining the stagnation pressure for the two- and the three-dimensional cases of flow around cylinders and spheres, respectively. The results thus obtained are compared with experimental results obtained in an oil channel at Reynolds numbers up to approximately 100. Finally, a procedure to determine the velocity and the pressure variation, as well as the variation of the free-stream velocity gradient on the stagnation streamline, is shown and used for the practical case of Reynolds number 100.

NACA TM 1338

THE OXIDATION OF METALS AND ALLOYS. (Uber das Zundern von Metalle und Legierungen). Erich Scheil. June 1952. 16p. diagrs., photos. (NACA TM 1338. Trans. from Zeitschrift für Metallkunde, v. 29, July 1937, p. 209-214).

This paper reviews the various types of oxidation processes occurring with pure metals and gives explanations for the varying time-temperature-oxidation rate relations that exist for copper, tungsten, zinc, cadmium, and tantalum. The effect of shape and crystal structure on oxidation is discussed. Principles derived are applied to the oxidation of alloys.

NACA TM 1339

VELOCITY OF ACTION OF OXYGEN, HYDROGEN SULFIDE, AND HALOGENS ON METALS. (Die Geschwindigkeit der Einwirkung von Sauerstoff, Schwefelwasserstoff, und Halogenen auf Metalle). G. Tammann and W. Köster. June 1952. 21p. diagrs., 20 tabs. (NACA TM 1339. Trans. from Zeitschrift für anorganische und allgemeine Chemie, v. 123, August 1922, p. 196-201 and 208-224).

This report discusses a method of determining the rate of surface oxidation of a metal by the change in the color of the surface film produced by reactions with oxygen, chlorine, or iodine. The metals studied included iron, nickel, copper, zinc, cadmium, tin, lead, cobalt, and manganese. Tables are given for surface film thickness versus color for various times.

NACA TM 1345

TRANSLATIONAL MOTION OF BODIES UNDER THE FREE SURFACE OF A HEAVY FLUID OF FINITE DEPTH. (O postupatelnom dvizhenii tel pod svobodnoi poverkhnost'yu tyazheloi zhidkosti konechnoi glubiny). M. D. Haskind. June 1952. 20p. diagr. (NACA TM 1345. Trans. from Prikladnaya Matematika i Mekhanika, v. 9, no. 1, September 1945, p. 67-78).

The problem of the uniform motion of a solid body under the free surface of a heavy incompressible fluid of finite depth is treated. The problem is a two-dimensional one and is handled completely by the methods of complex function theory.

N-3074B

INDEX OF NACA TECHNICAL PUBLICATIONS, 1949-MAY 1951. (Supplement to the index of NACA technical publications, 1915-1949). viii, 201p. (NACA)

This report, previously listed in Research Abstract no. 24 as being available for loan only, is now available for issue.

BRITISH REPORTS

N-14296*

Aeronautical Research Council (Gt. Brit.)
GENERAL HANDLING TESTS OF THE SIKORSKY R-4B HELICOPTER (HOVERFLY MK. I). W. Stewart. 1951. 21p. diagrs., photos., tab. (ARC R & M 2431; ARC 10,211. Formerly RAE Aero 2164)

Throughout the flying range, the stability of the helicopter is poor but the controls are very effective. The lateral control may be criticized as too sensitive. Maneuvers on the helicopter require a precise coordination of all controls, including the collective pitch and throttle controls. Vibration in the control column and lateral force required to trim, make it very tiring to fly the Hoverfly for any length of time. A loss of control is experienced at zero forward airspeed and high power conditions, when the collective pitch is reduced, unless the reduction is made very slowly.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF THE SWEEPBACK OF DELTA WINGS ON THE PERFORMANCE OF AN AIRCRAFT AT SUPERSONIC SPEEDS. A. Robinson and F. T. Davies. 1951. 6p. diagrs. (ARC R & M 2476; 10,594. Formerly College of Aeronautics, Cranfield Rept. 6)

The variation with sweepback of the total drag of an aircraft in level flight at supersonic speeds is calculated. It is shown that sweepback is not uniformly beneficial, but that in general the optimum amount of sweepback depends on the design speed and altitude.

N-14305*

Aeronautical Research Council (Gt. Brit.)
INTERFERENCE ON A WING DUE TO A BODY AT SUPERSONIC SPEEDS. S. Kirkby and A. Robinson. 1952. 10p. diagrs. (ARC R & M 2500; 10,631, FM 1113. Formerly College of Aeronautics, Cranfield Rept.7)

The wing-body combination considered consists of a right-circular conical body, of small semivertical angle, carrying an unswept symmetrical rectangular wing whose chord is inclined at a small angle to the axis of the body cone. In theory, the conical body is replaced by an axial doublet system and the upwash velocity increment is calculated at the midchord line of the wing. The resultant lift increment on the wing due to body interference is then calculated by Ackeret's theory. Curves are plotted to show the variation of induced wing-lift coefficient with cone angle for different wing positions.

N-14306*

Aeronautical Research Council (Gt. Brit.)
OVERALL THRUST, THRUST GRADING, AND TORQUE MEASUREMENTS ON A TWO-BLADE, 6-1/2 PER CENT THICK, NACA 16 SECTION PROPELLER IN THE HIGH-SPEED TUNNEL. G. S. Hislop, G. F. Hughes and D. S. Capps. 1951. 45p. diagrs., photos., tab. (ARC R & M 2515; 10,975. Formerly RAE Aero 2213)

Blade angles were varied and the solidity was 7-1/2 percent total solidity at 0.7R. The Mach number range was 0.1 to 0.8. It was concluded that it should be possible to obtain very good propulsive efficiencies at all forward speeds up to a Mach number of 0.78. Beyond that speed, orthodox propellers will be unsuitable. There was some uncertainty about the corrections to the experimental results.

Aeronautical Research Council (Gt. Brit.)
HIGH-SPEED WIND-TUNNEL TESTS ON MODELS OF FOUR SINGLE-ENGINED FIGHTERS (SPITFIRE, SPITEFUL, ATTACKER AND MUSTANG). Staff of the R.A.E. High Speed Wind Tunnel, edited by W. A. Mair. PART I. W. A. Mair, S. P. Hutton and H. E. Gamble. PART II. W. A. Mair, S. P. Hutton and H. E. Gamble. PART III. W. A. Mair and S. P. Hutton. PART IV. S. P. Hutton, D. A. Clark and D. J. Tremlett. PART V. J. Y. G. Evans, J. Caldwell and C. M. Britland. 1951. 79p. diagrs., tabs. (ARC R & M 2535; ARC 6739; ARC 7596; ARC 7045; ARC 9559; ARC 8707. Formerly RAE Aero 1810; RAE Aero 1908; RAE Tech.Note Aero 1247; RAE Aero 2112; RAE Aero 2038)

This report describes measurements of lift, drag, and pitching moment made in the RAE high-speed

wind tunnel on models of the Spitfire, Spiteful (F.1/43), Attacker (E.10/44), and Mustang. On the Spiteful model, pressure distributions on the front radiator flap were also measured. An introduction (written in 1949) gives a general account of the tests described in the separate parts of the report.

N-14308*

Aeronautical Research Council (Gt. Brit.)
TESTS ON A GLAS II WING WITHOUT SUCTION IN THE COMPRESSED AIR WIND TUNNEL. C. Salter, C. J. W. Miles and R. Owen. 1951. 21p. diagrs., 5 tabs. (ARC R & M 2540. Formerly ARC 11,269; Perf. 409; FM 1207)

The object of these tests was primarily the estimation of the behavior of the wing at high Reynolds numbers in the event of the failure of the suction, but the investigation was extended to the examination of the effect of main, split, and slotted flaps in order to obtain information concerning some reasonable method of countering any serious effects that might arise. Critical regions were observed and the scale effects were found to be large. The gain of maximum lift resulting from the use of main and split flaps was roughly 0.5 on C_L and has been shown to be less than half of the gain achieved on an NACA 0030 wing by the use of a similar split flap. The effect of slotting the main flap was found to be comparatively small and rather detrimental than otherwise.

NOTE ON THE SOUTHWELL METHOD FOR ESTIMATING CRITICAL LOADS. H. L. Cox. 1951. 8p. diagrs. (ARC R & M 2696. Formerly ARC 9852, ARC 10,374, Strut 1054, Strut 1054a)

Draws attention to certain restrictions on the use of the "Southwell plot" to estimate critical loads in cases differing in conditions from those for which the method was first proposed. The effect on this plot of various stress distributions, of elastic failure of the material and of other variations of critical stress, however it may be occasioned, is examined. The Southwell plot is strictly applicable only to deflections which go to infinity at a definite critical load. In other cases the plot usually overestimates the buckling load, but the error should seldom be important.

Aeronautical Research Council (Gt. Brit.)
AN INVESTIGATION INTO THE EFFECT OF FORCED AND NATURAL AFTERBODY VENTILATION ON THE HYDRODYNAMIC CHARACTERISTICS OF A SMALL FLYING BOAT (SARO 37) WITH A 1:20 FAIRING OVER THE MAIN STEP. J. A. Hamilton. 1951. 18p. diagrs., photos., tab. (ARC R & M 2714; ARC 11,360. Formerly MAEE F/Res/206)

A continuation of tests reported in R & M 2463 (in which the fairing was 1:15). The hydrodynamic characteristics were investigated in taxi runs and take-offs over a range of fixed elevator positions and in landing over a range of touch-down attitudes, at a weight of 5,900 lbs. These tests were made with the ducts naturally ventilated. At 6,200 lbs the tests were confined to taxi runs with and without forced ventilation.

Aeronautical Research Council (Gt. Brit.)
A REVIEW OF THE ESSENTIALS OF IMPACT FORCE THEORIES FOR SEAPLANES AND SUGGESTIONS FOR APPROXIMATE DESIGN FORMULAE. R. J. Monaghan. 1952. 27p. diagrs. (ARC R & M 2720; ARC 11,245. Formerly RAE Aero 2230)

This report reviews the essential theory and assumptions underlying recent work, and puts forward an approximate design formula for the maximum deceleration during a main step impact which is directly a function of the initial impact conditions.

N-14403*

Aeronautical Research Council (Gt. Brit.)
A 24-WAY HIGH-SPEED ROTARY SWITCH FOR USE IN STATIC AND AIRBORNE STRAIN GAUGE MEASUREMENTS. D. H. Peirson. 1951. 10p. diagrs., photos. (ARC R & M 2232; ARC 10,398. Formerly RAE Tech. Note SME 381)

A mechanical switch operating at 25 times per second for each signal has been designed to record 24 strain-gage signals, using a single amplifier and cathode-ray oscillograph. This equipment has been used in the measurement of steady ground and varying air-borne signals. Reference is made to use of the switch in static laboratory measurements on a tail plane and wing. Technique as developed for the measurement of wing stresses in flight is described in some detail.

N-14404*

Aeronautical Research Council (Gt. Brit.)
AN EXAMPLE IN WING THEORY AT SUPERSONIC SPEED. H. B. Squire. 1951. 16p. diagrs., tab. (ARC R & M 2549; ARC 10,624; ARC 12,517. Formerly RAE Aero 2184)

Calculations of the pressure on a flat elliptic cone and on a flat elliptic hyper-cone at supersonic speeds and zero incidence are made for the case when the cones lie inside the Mach cone of the apex. The results are combined to give the pressure distribution and drag of a wing-like surface at zero incidence in a supersonic stream. It is found that the pressure is constant along straight lines on this surface which are normal to the wind direction. The drag results show the effect of sweepback on drag at supersonic speeds.

Aeronautical Research Council (Gt. Brit.)
TESTS ON A WORKING MODEL RAM JET IN A SUPERSONIC WIND TUNNEL. J. R. Singham, F. W. Pruden and R. C. Tomlinson. 1951. 16p. diagrs., photos., 4 tabs. (ARC R & M 2568; ARC 11,361. Formerly NGTE R.20)

The tests were made to ascertain the practicability of testing such a small-scale model in a wind tunnel and to determine to what extent the external drag of a model duct tested hot would differ from the same model tested cold. The tests were run at a Mach number of 1.4. It was concluded that satisfactory accuracy could be obtained by the use of a large tunnel of square or rectangular section, with a good velocity distribution and transparent walls large enough to view the whole model.

Aeronautical Research Council (Gt. Brit.)
DESIGNING TO AVOID DANGEROUS BEHAVIOUR OF AN AIRCRAFT DUE TO THE EFFECTS ON CONTROL HINGE MOMENTS OF ICE ON THE LEADING EDGE OF THE FIXED SURFACE. D. E. Morris. 1952. 10p. diagrs., tab. (ARC CP 66)

Results of wind-tunnel measurements of hinge moments of a Viking elevator with simulated ice on the tail-plane leading edge are used to explain uncontrollable pitching oscillations of the aircraft which occurred during a flight. It is suggested that the imposing of certain limitations on the control-surface hinge-moment coefficients will eliminate the difficulty.

Aeronautical Research Council (Gt. Brit.)
APPROXIMATE TWO-DIMENSIONAL AEROFOIL THEORY. PART III. APPROXIMATE DESIGNS OF SYMMETRICAL AEROFOILS FOR SPECIFIED PRESSURE DISTRIBUTIONS. S. Goldstein. 1952. 40p. diagrs., 3 tabs. (ARC CP 70)

It is shown that if the velocity distribution at the surface of a symmetrical airfoil, according to the purely linear theory, is known, that the airfoil shape may be easily calculated. General formulas are given for the airfoil ordinates, both in terms of a Fourier series and as an integral. Examples are given.

N-14411*

Aeronautical Research Council (Gt. Brit.)
FLIGHT TESTS ON THE YOUNGMAN-BAYNES HIGH-LIFT EXPERIMENTAL AIRCRAFT. D. Lean. 1952. 54p. diagrs., photos., 9 tabs. (ARC CP 65)

The tests showed that an increment of maximum lift coefficient of 1.32 can be obtained on an unswept wing with a low-drag section, whose basic maximum lift coefficient is 1.28. About 0.2 was lost due to wing-fuselage interference. Adequate lateral control is provided by ailerons inset in the full-span flap. The profile-drag increment at full flap is 0.07 for a lift-coefficient increment of 1.14, at an angle of attack of 10°. Changes in longitudinal trim due to flaps are small and easily controlled and the ground effect on longitudinal trim is negligible. The wing-flap-aileron structure is adequately stiff in torsion and the aileron reversal speed is estimated at 300 knots.

N-14412*

Aeronautical Research Council (Gt. Brit.)
DRAFT CORRECTIONS FOR WATER SURFACE DEFLECTION UNDER NO. 1 CARRIAGE OF THE R.A.E. SEAPLANE TANK. T. B. Owen. 1952. 15p. diagrs., photo., 3 tabs. (ARC CP 67)

The running draft and attitude of hulls under test are measured relative to the undisturbed water level, but at normal running speeds an appreciable deflection of the water surface is produced at the model testing position by the aerodynamic pressure field of the carriage. These deflections have been measured and data are given for the correction of measured draft and attitude values covering the normal range of model positions and conditions.

APPROXIMATE TWO-DIMENSIONAL AEROFOIL THEORY. PART V. THE POSITIONS OF MAXIMUM VELOCITY AND THEORETICAL C_L-RANGE. S. Goldstein. 1952. 26p. diagrs. (ARC CP 72)

To calculate the theoretical critical compressibility speed for a given airfoil section at a given C_L we first compute the greatest velocity on the airfoil contour. Normal methods are often too long and thus a simplification is presented. This method is accurate enough for practical purposes. There is a discussion of the theoretical C_L-range for low-drag airfoils. The so called "roof-top" airfoils are considered in particular.

THE MEASUREMENT OF HEAT TRANSFER AND SKIN FRICTION AT SUPERSONIC SPEEDS. PART II - BOUNDARY LAYER MEASUREMENTS ON A FLAT PLATE AT M = 2.5 AND ZERO HEAT TRANSFER. R. J. Monaghan and J. E. Johnson. 1952. 44p. diagrs., photo., 2 tabs. (ARC CP 64)

The measured rate of growth of the laminar layer was greater than theory would predict. Transition to turbulent flow occurred between 3 and 4 inches from the leading edge at a Reynolds number between 8×10^5 and 10^6. The thickness of the turbulent layer was approximately the same as in low speed flow. Skin friction was about 20 percent below that obtained with the heated plate of the preceding report. A preliminary investigation was made of the use of chemical methods for indicating transition.

APPROXIMATE TWO-DIMENSIONAL AEROFOIL THEORY. PART II. VELOCITY DISTRIBUTIONS FOR CAMBERED AEROFOILS. S. Goldstein. 1952. 61p. diagrs., 5 tabs. (ARC CP 69)

Both thickness and camber are considered in this theory. The connection with the "vortex sheet" theory of infinitely thin airfoils is set out. In particular, the usual formulas for the no-lift angle and moment at zero lift are correct if account is taken of the thickness, so long as the thickness is not too large. Examples are given.

STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART V. IGNITION DELAY MEASUREMENTS ON HYDROCARBONS. B. P. Mullins. October 1951. 73p. diagrs., 46 tabs. (NGTE R.97)

Ignition delay measurements were made upon some pure hydrocarbons and petroleum products using the continuous method. The fuels were paraffins, aromatics, unsaturateds, naphthalene derivatives, cyclo-compounds, terpenes, and petroleum products. Although ignition delay curves of the petroleum products lie close together, considerable differences in positions and slopes of the curves for single hydrocarbon compounds were noted. Observations of flame color were made and activation energies of reaction were computed for each fuel.

COMBUSTION OF DILUTE METHANE-AIR MIXTURES. H. Bruce Cox and N. P. W. Moore. January 1952. 21p. diagrs., photo., 2 tabs. (NGTE R.113)

Combustion of these fuels has been investigated in a conventional gas-turbine combustion chamber with a secondary reaction duct at outlet temperatures between 650° and 900° C and from 1 to 3 atmospheres static pressure. The efficiency reached 95 percent at 890° C. At lower temperatures, the efficiency fell due partly to the conversion to carbon monoxide of a considerable part of the methane which did react. Pressure has been shown to be unimportant within the range investigated except for causing a small reduction in the yield of carbon monoxide at the higher pressures. Oxidation in the secondary duct was slow. Extended residence time was found to be essential for high combustion efficiencies.

METHOD OF QUALITATIVE BOUNDARY LAYER INVESTIGATION BY MEANS OF HOT WIRES PLACED IN THE WING BELOW STATIC PRESSURE ORIFICES. (Methode voor kwalitatief grenslaagonderzoek met behulp van gloeidraden zonder beinvloeding der stroming). P. C. A. Malotaux, J. J. Denier van der Gon and Yap Kie Jan. January 1952. 31p. diagrs. (RAE Library Trans. 397. Trans. from Technische Hoogeschool te Delft, Sub-Afd. Vliegtuigbouwkunde, Rapport VTH 45)

This report describes a method for qualitative boundary layer investigation, using hot wires, in which the flow remains undisturbed. Its application to the determination of the local character of the boundary layer flow past a wing surface is described. This can be deduced from the behavior of hot wires located not in the boundary layer itself but below static pressure orifices in the wing surface. As the flow remains undisturbed the method can be combined with measurements of the chordwise pressure distribution and wake measurements of the profile drag.

AN EXAMINATION OF THE TECHNIQUE OF THE MEASUREMENT OF THE LONGITUDINAL MANOEUVRING CHARACTERISTICS OF AN AEROPLANE, AND A PROPOSAL FOR A STANDARDISED METHOD. D. J. Lyons. 1952. 33p. diagrs. (ARC R & M 2597; ARC 11,159. Formerly RAE Aero 2223)

It is demonstrated that the "steady stick force per g" as defined by Gates and Lyon in R & M 2027 is the best criterion for the measurement of maneuverability of an aircraft because it indicates the minimum stick force that has to be exerted by the pilot to break the aircraft and its value is obtained in flight by a definite test procedure. It is further concluded that some additional criterion may be used to insure that unduly heavy forces are not encountered during sharp pull-outs. A method of measuring the steady stick force per g has been developed at the RAE which, it is suggested, should be standardized for such tests throughout the country. The results of this method have been demonstrated on two aircraft.

PRESSURE PLOTTING TESTS IN THE ROYAL AIRCRAFT ESTABLISHMENT HIGH SPEED WIND TUNNEL ON A 21 PER CENT THICK, LOW DRAG AEROFOIL (BRABAZON I WING ROOT SECTION). A. B. Haines and W. Port. 1952. 24p. diagrs., 2 tabs. (ARC R & M 2617; ARC 11,116. Formerly RAE Aero 2224)

The subject tests covered a Mach number range up to 0.7 at a Reynolds number of about 3×10^6 and low speed tests were extended up to $R = 9.45 \times 10^6$. The results have shown that: (1) No serious compressibility effects on C_L and C_m occur in the cruising conditions (M up to 0.6, C_L up to 0.66). (2) $C_{L_{max}}$ remains roughly constant at about 1.15 up to M = 0.6, and then falls to 1.01 for M = 0.7. (3) For M = 0.2, $C_{L_{max}}$ increases from 1.17 for $R = 3 \times 10^6$ to 1.26 for $R = 9.45 \times 10^6$. (4) The reason for the maintenance of $C_{L_{max}}$ seems to be a backward movement of the peak suction which is not found on other sections. (5) Two distinct C_L versus α curves beyond the stall are obtained at low Mach number. It appears that there is adequate margin between the cruising and stalling conditions to provide maneuverability and safety in upgusts.

HIGH SPEED WIND TUNNEL TESTS ON AN AIRFOIL WITH AND WITHOUT TWO-DIMENSIONAL SPANWISE BULGES. J. A. Beavan, E. W. E. Rogers and R. Cartwright. 1952. 34p. diagrs., photos., 2 tabs. (ARC CP 78)

One bulge had a height of 0.004 chord and extended from 0.3-0.5 chord. The other bulge was one-half of both these dimensions. Pressure distributions at low speeds agreed with theory. The C_L is generally greater than for the plain airfoil, but the corresponding changes in C_m are small except at higher speeds. At low speeds and zero angle of attack, boundary-layer transition took place near the bulge centers compared with 0.75 chord for the plain airfoil. The resulting increase in C_D agrees with theory. With increase in Mach number, an initial rise in drag (due to shock waves on the bulge) occurs at angles of attack of 0° and 2°. This rise is halted as the main shock wave and transition point move back and the final drag rise takes place at about the same Mach number as on the plain airfoil. Shock waves are stronger and better defined on the warped than on the plain airfoil.

THE EIGENVALUES OF SOME STABILITY PROBLEMS INVOLVING VISCOSITY. Cathleen S. Morawetz. December 1951. 37p. diagrs. (Massachusetts Inst. of Tech.)

Small disturbances are assumed to occur in viscous flow between moving walls, with a symmetrical velocity profile between two fixed walls, and in a boundary layer along a flat plate. Corresponding to each such problem for the viscous fluid, there is a simpler problem with viscosity zero. It is natural to conjecture that, for large Reynolds numbers, the eigenvalues in the complete viscous problem are related to those in the corresponding inviscid problem. The present investigation justifies the relationship between viscous and inviscid eigenvalues in most cases and in fact expresses these viscous eigenvalues asymptotically with respect to the Reynolds number in terms of the inviscid eigenvalues.

COMPARISON OF NATIONAL BUREAU OF STANDARDS CERAMIC COATINGS L-7C AND A-417 ON TURBINE BLADES IN A TURBOJET ENGINE. C. Robert Morse. December 22, 1948. photos., 5 tabs. (NACA RM E8I20) (Declassified from Restricted, 3/28/52)

An investigation was conducted to determine which of two ceramic coatings L-7C and A-417 developed by the National Bureau of Standards was the more suitable as a protective coating for gas-turbine blades. Four cast Vitallium blades, two coated with each of these ceramics, were installed in the turbine wheel of a turbojet engine and subjected to 20 minute cycles consisting of 5 minutes at idle and 15 minutes at rated speed. Ceramic coating A-417 showed no evidence of fusion during 100 operating cycles. Ceramic coating L-7C showed evidence of fusion and radial flow, indicating that the fusion temperature of the coating is too low for satisfactory service in the turbojet engine.

CURRENT NACA REPORTS

NACA TN 2711

THE AERODYNAMIC DESIGN OF HIGH MACH NUMBER NOZZLES UTILIZING AXISYMMETRIC FLOW WITH APPLICATION TO A NOZZLE OF SQUARE TEST SECTION. Ivan E. Beckwith, Herbert W. Ridyard and Nancy Cromer. June 1952. 30p. diagrs., 5 tabs. (NACA TN 2711)

A method is given for the design of three-dimensional nozzles utilizing axisymmetric flow to produce uniform flow in a test chamber of arbitrary cross section. The method is applied to obtain the coordinates of a Mach number 10 nozzle for which a square test section is specified. Radial flow is used in a portion of the flow field to reduce the computation time. The remainder of the flow field is computed by the method of characteristics, but a simplified method is used near the axis. Tables which facilitate computation of the radial flow and the flow near the axis are included. Transition streamlines determined from the analytic expressions of Kuno Foelsch are compared with the streamlines obtained from the characteristic net of the Mach number 10 nozzle.

NACA TN 2720

EFFECTS OF ASPECT RATIO ON AIR FLOW AT HIGH SUBSONIC MACH NUMBERS. W. F. Lindsey and Milton D. Humphreys. July 1952. 10p. photos., diagrs. (NACA TN 2720. Formerly NACA RM L8G23)

Schlieren photographs were used in an investigation to determine the effects of changing the aspect ratio from infinity to 2 on the air flow past a wing at high subsonic Mach numbers. The results indicated that the decreased effects of compressibility on drag coefficients for the finite wing are produced by a reduction in the compression shock and flow separation.

NACA TN 2724

TRANSONIC SIMILARITY RULES FOR LIFTING WINGS. Keith C. Harder. June 1952. 26p. diagr. (NACA TN 2724)

Transonic similarity rules for lifting wings at small angles of attack are derived. These rules make it possible to present each aerodynamic coefficient for a family of wings of varying aspect ratio and thickness ratio in a single design chart for the transonic range.

NACA TN 2726

ON THE APPLICATION OF TRANSONIC SIMILARITY RULES. John R. Spreiter. June 1952. 45p. diagrs. (NACA TN 2726)

The transonic aerodynamic characteristics of wings of finite span are discussed from the point of view of a unified small perturbation theory for subsonic, transonic, and supersonic flows about thin wings. This approach avoids certain ambiguities which appear if one studies transonic flows by means of equations derived under the more restrictive assumption that the local velocities are everywhere close to sonic velocity. The relation between the two methods of analysis of transonic flow is examined, the similarity rules and known solutions of transonic flow theory are reviewed, and the asymptotic behavior of the lift, drag, and pitching-moment characteristics of wings of large and small aspect ratio is discussed. It is shown that certain methods of data presentation are advantageous for the effective display of these characteristics.

NACA TN 2727

EXPERIMENTS IN EXTERNAL NOISE REDUCTION OF A SMALL PUSHER-TYPE AMPHIBIAN AIRPLANE. John P. Roberts and Leo L. Beranek, Aeronautical Research Foundation. July 1952. 142p. diagrs., photos., 3 tabs. (NACA TN 2727)

As part of a program to find practicable ways of reducing the external noise level of light airplanes, noise measurements were made on a representative pusher-type amphibian airplane. Tests were made with a standard airplane and with modified versions of the airplane equipped with a geared engine, exhaust muffler, and propellers with various numbers of blades. Sound-level recordings were made of take-offs; of overhead flights at 100- and 500-foot altitude; and, for some configurations, of flights at 500-foot altitude passing 3000 feet away. The tests also included analyses of sound-frequency components with the airplane on the ground from a distance of 50 feet and at various positions around the airplane. The results are compared with measurements from a previous noise study of a tractor-type airplane.

NACA TN 2730

CHOKING OF A SUBSONIC INDUCTION TUNNEL BY THE FLOW FROM AN INDUCTION NOZZLE. W. F. Lindsey. July 1952. 20p. diagrs. (NACA TN 2730)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C, CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A decrease in Mach number with increase in induction jet pressure has been shown experimentally, for one type of induction tunnel, to be associated with choking of the induced flow. The analysis of the flow conditions provides a means of predicting the occurrence of induction choking so that it can be adequately considered in design.

NACA TN 2732

THEORETICAL INVESTIGATION OF VELOCITY DIAGRAMS OF A SINGLE-STAGE TURBINE FOR A TURBOJET ENGINE AT MAXIMUM THRUST PER SQUARE FOOT TURBINE FRONTAL AREA. (Revised). Leo Cohen. June 1952. 34p. diagrs., tab. (NACA TN 2732)

The aerodynamic requirements of a single-stage turbine for a turbojet engine at maximum thrust per square foot turbine frontal area are presented in the form of velocity diagrams. An impulse diagram with supersonic velocities relative to the leading and trailing edges of the rotor is required for practically all blade speeds and turbine-inlet temperatures investigated.

NACA TN 2733

METHOD FOR CALCULATION OF HEAT TRANSFER IN LAMINAR REGION OF AIR FLOW AROUND CYLINDERS OF ARBITRARY CROSS SECTION (INCLUDING LARGE TEMPERATURE DIFFERENCES AND TRANSPIRATION COOLING). E. R. G. Eckert and John N. B. Livingood. June 1952. 71p. diagrs. (NACA TN 2733)

A method which permits approximation of local heat-transfer coefficients in the laminar-flow region around cylinders of arbitrary cross section from those for wedge-type profiles is extended to include the effects of large temperature differences and transpiration cooling. Charts prepared from exact solutions of the laminar boundary-layer equations for wedge-type profiles which allow for these effects yield results with a minimum of calculation. Application of the method to circular and elliptic transpiration-cooled cylinders is made to determine local heat-transfer coefficients and surface temperatures and to determine the variation in coolant flow required for maintaining a constant surface temperature.

NACA TN 2735

AN ANALYSIS OF THE NORMAL ACCELERATIONS AND AIRSPEEDS OF A TWO-ENGINE TYPE OF TRANSPORT AIRPLANE IN COMMERCIAL OPERATIONS ON ROUTES IN THE CENTRAL UNITED STATES FROM 1948 TO 1950. Walter G. Walker and Paul W. J. Schumacher. July 1952. 30p. diagrs., 4 tabs. (NACA TN 2735)

Normal-acceleration and airspeed data obtained from a two-engine type of transport airplane are analyzed to determine the gust and gust-load experiences of the airplane. The gust and gust-load experiences are compared with similar results from the same type of airplane during past operations. The influences of the gusts and the operating speeds in rough air on the gust-load experience are indicated.

NACA TN 2736

TWO-DIMENSIONAL SHEAR FLOW IN A 90° ELBOW. James J. Kramer and John D. Stanitz. July 1952. 44p. diagrs. (NACA TN 2736)

As part of an approach to a better understanding of the motion of real fluids in flow machinery, two-dimensional, incompressible, nonviscous shear flows in a 90° elbow have been investigated. Solutions are presented for linear and sinusoidal velocity distributions across the inlet of the elbow. The solutions with linear inlet velocity distributions indicate that as the negative vorticity of the flow increased: (1) the static-pressure drop through the elbow decreased, (2) the local deceleration along the outer channel walls increased, and (3) the magnitude of the velocities on the channel walls changed greatly, but the local pressure coefficient rose only gradually and the difference in pressure coefficient at corresponding points on the two walls was practically unchanged. In the case of a sinusoidal inlet velocity distribution, local decelerations occurred on both walls.

NACA TN 2738

A PROBABILITY ANALYSIS OF THE METEOROLOGICAL FACTORS CONDUCTIVE TO AIRCRAFT ICING IN THE UNITED STATES. William Lewis and Norman R. Bergrun. June 1952. 93p. diagrs., 11 tabs. (NACA TN 2738)

Meteorological icing data obtained in flight in the United States are analyzed statistically and methods are developed for the determination of (1) the various simultaneous combinations of the three basic icing parameters (liquid-water content, drop diameter, and temperature) which would have equal probability of being exceeded in flight in any random icing encounter, and (2) the probability of exceeding any specified group of values of liquid-water content associated simultaneously with temperature and drop-diameter values lying within specified ranges.

NACA TN 2740

EXPERIMENTAL INVESTIGATION OF THE LOCAL AND AVERAGE SKIN FRICTION IN THE LAMINAR BOUNDARY LAYER ON A FLAT PLATE AT A MACH NUMBER OF 2.4. Randall C. Maydew and Constantine C. Pappas. July 1952. 22p. diagrs. (NACA TN 2740)

Average and local skin-friction coefficients for laminar flow have been determined experimentally on a flat plate at a Mach number of 2.4 for a Reynolds number range of 0.72×10^6 to 2.8×10^6 and compared with the laminar-boundary-layer theory of Chapman and Rubesin. The average skin-friction data were considerably higher than values predicted by laminar-boundary-layer theory. Local skin-friction coefficients, evaluated by the two methods, agreed well with the theory when plotted against a momentum-thickness Reynolds number.

NACA TN 2742

BOUNDARY-LAYER DEVELOPMENT AND SKIN FRICTION AT MACH NUMBER 3.05. Paul F. Brinich and Nick S. Diaconis. July 1952. 49p. diagrs., photos. (NACA TN 2742)

Boundary-layer studies consisting of schlieren observations and momentum surveys were made on hollow cylinder models with their axes alined parallel to the stream. Results were obtained for three model diameters and for natural and artificially induced turbulent boundary-layer flows. Transition Reynolds numbers were found to decrease with decreases in leading-edge thickness and with reductions in tunnel pressure level. Turbulent temperature-recovery factors generally decreased with increasing Reynolds number and were a maximum for the smallest transition Reynolds numbers. The results of this investigation appeared to be consistent with the theoretical turbulent friction formulas of Wilson and with the extended Frankl-Voishel analysis of Rubesin, Maydew, and Varga. Velocity profiles in the outer portion of the boundary layer could be approximated reasonably with a 1/7 power profile and were found to be approximately similar in this region. Velocity profiles given by the Kármán universal turbulent boundary-layer profile parameters were found to be similar in the laminar sublayer and in the turbulent region.

NACA RM E52D17

EXPERIMENTAL INVESTIGATION OF AVERAGE HEAT-TRANSFER AND FRICTION COEFFICIENTS FOR AIR FLOWING IN CIRCULAR TUBES HAVING SQUARE-THREAD-TYPE ROUGHNESS. Eldon W. Sams. June 1952. 43p. diagrs., photos. (NACA RM E52D17)

A heat-transfer investigation was conducted with air flowing through electrically heated Inconel tubes having various degrees of square-thread-type roughness (conventional roughness ratios of 0 (smooth tube), 0.016, 0.025, and 0.037), an inside diameter of 1/2 inch, and a length of 24 inches over ranges of bulk Reynolds number up to 350,000 and average inside-tube-wall temperatures up to 1950° R. The data showed that both heat transfer and friction increased with increase in surface roughness (particularly at the higher Reynolds numbers) and were also influenced by tube wall-to-bulk temperature ratio. Good correlation of the heat-transfer data for all tubes was obtained by use of a modified Reynolds number including the friction velocity. Correlation of the friction data for the rough tubes was obtained for the complete turbulence region by use of a modified correlation incorporating a roughness parameter which excludes the conventional roughness ratio; no over-all correlation was obtained for the region of incomplete turbulence.

NACA RM E52D24

SOLUBILITY OF WATER IN HYDROCARBONS. R. R. Hibbard and R. L. Schalla. July 1952. 25p. diagrs., 3 tabs. (NACA RM E52D24)

An equation is presented which may be used to estimate the solubility of water in any nonolefinic hydrocarbon or hydrocarbon blend at any temperature. Only the temperature and the hydrogen-to-carbon ratio of the hydrocarbon need be known to calculate solubilities which are believed to be sufficiently accurate for most engineering purposes.

NACA RM E52E19

USE OF FENCES TO INCREASE UNIFORMITY OF BOUNDARY LAYER ON SIDE WALLS OF SUPERSONIC WIND TUNNELS. Rudolph C. Haefeli. July 1952. 15p. diagrs., photos., tab. (NACA RM E52E19)

An investigation of the use of solid fences installed on the side walls of a supersonic wind tunnel to retard the development of transverse flow and thus to increase the uniformity of the side-wall boundary layer is reported. Beneficial results were obtained with fences which had depths of the order of the boundary-layer displacement thickness and which followed potential-flow streamlines through the nozzle. Reduction of the number of fences on each side wall from four to two eliminated their effectiveness.

NACA TM 1223

SOME EXPERIENCES REGARDING THE NONLINEARITY OF HOT WIRES. (Quelques expériences sur la non-linéarité des fils chauds). R. Betchov and W. Welling. June 1952. 13p. diagrs. (NACA TM 1223. Trans. from Koninklijke Nederlandsche Akademie van Wetenschappen te Amsterdam, Verhandelingen, v.53, no.4, 1950, p.432-439; Technische Hoogenschool te Delft, Laboratorium voor Aero- en Hydrodynamica. Mededeling 66).

Hot-wire experiments illustrate some differences between the resistance characteristics as given by King's equation and those for a finite wire length. The experiments support previous theoretical work which accounted for a heat loss although the wire ends and a dependence of the convective heat loss on a nonlinear function of the temperature difference between the wire and the air.

NACA TM 1346

NONLINEAR THEORY OF A HOT-WIRE ANEMOMETER. (Théorie non-linéaire de l'anémomètre à fil chaud). R. Betchov. July 1952. 23p. diagrs. (NACA TM 1346. Trans. from Koninklijke Nederlandsche Akademie van Wetenschappen te Amsterdam, Verhandelingen, v. 52, no. 3, 1949, p. 195-207; Technische Hoogenschool te Delft, Laboratorium voor Aero- en Hydrodynamica. Mededeeling 61).

A theoretical analysis is presented for the hot-wire anemometer to determine the differences in resistance characteristics as given by King's equation for an infinite wire length and those given by the additional considerations of (a) a finite length of wire with heat loss through its ends and (b) heat loss due to a nonlinear function of the temperature difference between the wire and the air.

THE MECHANICAL CHARACTERISTICS OF PNEUMATIC TYRES. R. Hadekel. March 1950. iii, 146p. diagrs., photos. (MOS S & TM 5/50)
RESTRICTED

The object of this report is to give an exposition of the existing knowledge of the mechanical properties, characteristics and behavior of pneumatic tires, insofar as they may be of interest to the user. Questions of tire technology are not discussed. The rolling process, vertical and horizontal load-deflection characteristics, behavior during braking and sideways motion, rolling resistance and high speed effects are all dealt with. Where possible, both theoretical treatment and empirical data are given. Recommendations are made with respect to further research. The primary object of the investigation was to provide data for aircraft purposes, but it is hoped that the information here presented will also be of use to land vehicle designers.

SANDWICH CONSTRUCTION AND CORE MATERIALS. PART V. W. J. Pullen. 1952. 14p. diagrs., photos., 5 tabs. (ARC R & M 2686; ARC 10,501. Formerly ARC 9017; Strut 938; Plas. 57)

Tensile, compressive and creep tests have been carried out on four different samples of extruded cellular cellulose acetate. It is concluded that the material is comparable with calcium alginate and other low-density materials so far handled in the Engineering Division, N. P. L. In particular, the samples are not subject to the same degree of "softening" as has been the case with some similar materials. The "filled" samples are more efficient than the "unfilled" ones and are worth considering as possible low-density stabilizers in sandwich construction.

A REVIEW OF SOME STALLING RESEARCH. A. D. Young. WITH AN APPENDIX ON WING SECTIONS AND THEIR STALLING CHARACTERISTICS. H. B. Squire and A. D. Young. 1951. 39p. diagrs., 5 tabs. (ARC R & M 2609; ARC 5751. Formerly RAE Aero 1718)

Over a period of years a considerable amount of stalling research on various airplanes was completed at the Royal Aircraft Establishment and it was considered desirable that the main results should be summarized and reviewed. The report includes a general discussion of the effect on stalling behavior of wing section, plan form, washout, flaps, nacelles, gills, slipstream, automatic wing-tip slots and Hudson-type slits. The important part that is played by the longitudinal trim and stability at incidences near the stall is emphasized. The relation between wing sections and their stalling characteristics is discussed and it is shown that the stalling characteristics can be broadly predicted from an examination of the form of the wing-section upper-surface pressure distribution at high incidences. The results indicate that vicious stalling behavior can be avoided by the use of wing sections towards the tip of fairly high camber (3 to 4 percent) and moderate thickness (> 12 percent). For some types of airplanes there are, however, serious objections to the use of high camber towards the tips; the designer is then advised to avoid wing sections which experiments and theory indicate have particularly bad stalling characteristics. The worst tip thickness for stalling appears to be in the region of 9 percent. High taper tends to worsen the stalling behavior and it is advisable to consider taper ratios greater than 2:1 only in conjunction with wing-tip sections having good stalling characteristics. The use of part-span flaps does not appear to cause any marked deterioration in stalling behavior, and frequently it improves the behavior; but there is some evidence, though not yet conclusive, that the use of full-span flaps may be accompanied by an appreciable worsening in stalling behavior. Attention is drawn to the advisability of examining the flow at high incidences in the neighborhood of the tail-plane of an airplane in the design stage, with a view to assessing its probable stalling behavior; in particular, the possibilities of designing for some stall warning can then be examined.

THE DIFFUSION OF TRANSVERSE LOADS IN A REINFORCED CIRCULAR CYLINDER WITH NON-RIGID FRAMES. S. R. Lewis. 1952. 23p. diagrs. (ARC CP 74)

Explores the variation of shear stress distribution at a loaded frame consequent upon the variation of several geometric parameters such as frame stiffness, skin thickness, stringer spacing, etc. Figures indicate the shear distribution around a frame for a single concentrated radial load of 1000 lb. The parameters chosen are those common to aircraft design, and it is possible to obtain a reasonably accurate shear distribution around a frame from the data supplied, without doing the actual lengthy shear calculation. The work is confined to the particular case where the loaded frame is removed from the end of the cylinder. Gives method of obtaining the shear load due to a tangential load and moment from the radial load expressions.

THE EFFECTS OF ATMOSPHERIC HUMIDITY AND TEMPERATURE ON THE ENGINE POWER AND TAKE-OFF PERFORMANCE OF A HASTINGS I. G. Jackson. 1952. 34p. diagrs., 9 tabs. (ARC CP 77)

Engine power decreases with increasing humidity and reduction is greatest at take-off engine speed and boost. Specific humidity will rarely exceed 2-1/2 percent and this will decrease take-off power approximately 10 percent as compared with dry air. The take-off distance to clear a 50 ft. obstacle would be increased about 17 percent. For take-off conditions, humidity is a parameter of the same order of importance as temperature. At constant humidity the rate of decrease of power with increase of temperature is not very different from the value given by the standard formula below full-throttle height. No effect of humidity on fuel consumption has been detected. Fuel consumption decreases with increase in temperature.

AN EXPERIMENTAL INVESTIGATION OF THE PERFORMANCE OF A PILOT PLANT FOR DRYING AIR BY SOLID GRANULAR ADSORBENTS. P. J. Bateman. 1952. 44p. diagrs., 2 tabs. (ARC CP 79)

An investigation was undertaken to measure the performance on a pilot plant scale of uncooled beds of granular adsorbent when drying air to the low humidities required for supersonic wind tunnel operation. Two size grades of activated alumina and one of silica gel were tested in a bed 2-1/2 by 2-1/2 feet in plan, and of various depths between 12 and 25 inches. The bed was worked throughout at about atmospheric pressure and air was drawn from atmosphere without treatment for humidity or temperature. The results are presented, in the main, as graphs of mean bed concentration $\left(\frac{\text{mass of water adsorbed}}{\text{mass of activated adsorbent}}\right)$ against inlet humidity for two values of the outlet humidity, 0.0005 and 0.0002 lb water/lb air. It is shown that over the ranges of the variables encountered the mean bed concentration decreases with increasing inlet humidity, increases with increasing bed depth at a fixed contact time, and decreases with increasing grain size. Although a definitive comparison is not possible there does not appear to be much difference in the performance of silica gel and activated alumina of the same grain size.

WIND TUNNEL TESTS ON A 90° APEX DELTA WING OF VARIABLE ASPECT RATIO (SWEEPBACK 36.8°). PART I. GENERAL STABILITY. J. G. Ross, R. Hills and R. C. Lock. PART II. MEASUREMENTS OF DOWNWASH AND EFFECT OF HIGH LIFT DEVICES. R. C. Lock, J. G. Ross and P. Meiklem. 1952. 67p. diagrs., photos., 26 tabs. (ARC CP 83)

Part I. Longitudinal and lateral stability measurements have been made in a low speed tunnel on a delta wing of 90° apex angle with three different taper ratios. The tests included measurements with ground, the effect of a body, and measurements of elevon power. $C_{L_{max}}$ was 0.86 for all taper ratios but was reduced to a trimmed value of 0.65 with a static margin of $0.10\bar{c}$, due to the large loss of lift caused by the elevons. A tip stall starts on the wings at $\alpha \doteq 8^{\circ}$ to 12° depending on the taper ratio; this has comparatively little effect on pitching moments but a large effect on both rolling and yawing moments, n_v and $-l_v$ both decreasing after the tip stall. C.A.T. tests suggest that there is an appreciable favorable scale effect on the tip stall. Ground effects are small and can be estimated sufficiently accurately using existing theoretical work on unswept wings. Part II. Wind-tunnel measurements of downwash were made on delta wings of aspect ratios 4, 3, and 2.3, using a tail of delta plan form in three vertical positions at two chordwise stations behind the wing. The tests also included the effect of the tail, and of split flaps and nose flaps, on the stability near the stall and on $C_{L_{max}}$. The tip nose flaps proved effective in delaying the tip stall, and gave some increase in $C_{L_{max}}$. With split flaps untrimmed $C_{L_{max}}$ was 0.95 and 1.2 with the flap in the forward and rear position respectively. There was no change of trim with the flaps in the forward position with tail off; with the tail an intermediate flap position should give zero trim change. The downwash was large at high lift coefficients, owing to the early tip stall, and this caused a loss of tail efficiency with a corresponding slight instability near the stall, which should not be serious. A method is given of calculating the downwash at small incidences behind a delta wing, and the results show good agreement with the measured values, provided that the experimental lift-curve slope is used.

Aeronautical Research Council (Gt. Brit.)
A THEORETICAL INVESTIGATION OF THE RESPONSE OF A HIGH-SPEED AEROPLANE TO THE APPLICATION OF AILERONS AND RUDDERS. K. Mitchell, A. W. Thorpe and E. M. Frayn. 1952. 92p. diagrs., 6 tabs. (ARC R & M 2294; ARC 8831; ARC 9639. Formerly RAE Aero 2040; RAE Aero 1952)

The response of a fast moving airplane to a lateral gust, and to applied rolling and yawing moments, is examined by means of the differential analyzer, taking a range of values of the principal lateral stability parameters, and including sufficient ranges of the other stability and inertia parameters to make the conclusions of general validity for high-speed flight. The motion following a sharp-edged side-gust is shown to be a markedly oscillatory character, with an unpleasantly short period, particularly in small airplanes. The shortness of the period is probably the worst feature. A general survey is made of the dependence of the motion upon the various parameters, the differential analyzer results being supplemented by the use of approximate formulas, which were developed with a view to this application. Particular attention is paid to the amplitudes of the motion in roll, yaw, and sideslip, and it is seen that it may be difficult to make the motion less unpleasant. The period may be lengthened by reducing n_v, but the improvement that is possible in this way is limited. Damping can be improved by reducing dihedral, or by increasing body side area: the addition of a forward fin, ahead of the center of gravity, would therefore be doubly helpful, lengthening the period and improving the damping. In studying response to applied moments attention is chiefly concentrated upon response to ailerons, and the theoretical results are compared with a theoretical standard motion produced by a constant rolling moment together with a yawing moment varied so as to suppress sideslip. Response at high speeds is shown to be insensitive to changes in l_v and n_v within their normal ranges, and good response to pure rolling moment is assured for all lateral stability characteristics other than those associated with the combination of small fin with large dihedral: this combination is worst at high values of the lateral relative density. The effect of adverse yawing moment from the ailerons is detrimental, and becomes worse as the dihedral is increased or fin area decreased.

Aeronautical Research Council (Gt. Brit.)
LATERAL RESPONSE THEORY. K. Mitchell. APPENDICES. E. M. Frayn. 1952. 57p. 8 tabs. (ARC R & M 2297; ARC 7933; ARC 8278; ARC 8544. Formerly RAE Aero 1925; RAE Tech. Note Aero 1513; RAE Tech. Note Aero 1584)

It is usual, when investigating the response of an airplane to applied forces and couples, to examine its behavior when disturbed by rolling and yawing moments, instantaneously or linearly applied. The relevant curves can be readily obtained by means of a differential analyzer: their calculation by existing methods is extraordinarily tedious, and analysis of lateral response, on a basis of the curves alone, a matter of some difficulty. The need was therefore felt for some new approach to the subject which would offer an alternative method of assessing response. A method is now given, whereby the calculation of response to any forces whatever is made to depend upon the prior determination of a number of constants, for which the name "modal response coefficients" is proposed. The idea of the method is introduced by solving first by the method of variation of constants; later the relevant formulas are more simply obtained by operational methods. It is shown that the Laplace transformation scores over Heaviside's methods here in leading at once to a result of considerable generality and in a form more convenient for computation. Methods for calculating model response coefficients and response curves are examined in appendices, recommended methods being presented as routine computations to be carried out on printed computing sheets (given as tables 1 and 2). "Optimum-interval" tables of certain functions occurring in the calculation of response curves are also given (tables 3 to 8). As a method of calculating response curves, even with the tabular aids presented here, the method of modal response coefficients is probably slightly less laborious than the usual methods: this work should be handled mechanically by the differential analyzer. The calculation of the modal response coefficients themselves, however, is not tedious, and may usefully be undertaken to aid in the study of curves calculated by other means. It is hoped that, when a little experience has been gained, it may prove possible to discuss response in terms of the modal response coefficients alone.

Aeronautical Research Council (Gt. Brit.)
RELAXATION TIME EFFECTS IN GAS DYNAMICS. J. C. Gunn. 1952. 44p. diagrs., 12 tabs. (ARC R & M 2338. Formerly ARC 9536; FM 910; TP 145; TJR 89)

In the formulation of the equations of gas dynamics it is usual to make certain simplifying assumptions concerning the properties of the gas under consideration. Thus, the equations are greatly simplified if it can be assumed that the gas is a perfect one, satisfying the equation $p/\rho = RT$, and also that the specific heat, C_p, is a constant. A further assumption, generally made, is that the energy content of the gas is capable of instantaneous change following the external conditions, so that the internal energy is always a uniquely defined function of the temperature. These assumptions are, of course, often justified in practice, but there is need for caution in applying them to unfamiliar gases, or, as we shall see, to cases where the temperature range of the process is very wide. The object of this note, in particular, is to study the third of the assumptions referred to above, and we shall investigate the effect on various dynamical processes of

the known time lag in the picking-up, by the vibrational degrees of freedom of a gas, of their equilibrium energy. Three main cases will be considered: (1) flow in a wind tunnel, (2) flow round an airfoil, without shock waves, and (3) flow through shock waves. The case of propagation of sound in a medium exhibiting heat capacity lag is also briefly discussed. The aim of the consideration is twofold: firstly, to demonstrate how small the effects of heat capacity lag are in most aerodynamic phenomena, and secondly to indicate some special cases in which the effects become more important. The preliminary physical data concerning the vibrational energy of a gas, and its adjustment to equilibrium, have been fairly fully presented in papers by Kantrowitz, and, more particularly by Bethe and Teller[2]. As these papers may not be readily accessible the opportunity is first taken to summarize this basic physical knowledge. Some of the more general consequences of the heat-capacity lag are also deduced.

WINGS OF FINITE ASPECT RATIO AT SUPERSONIC VELOCITIES. D. R. Taunt and G. N. Ward. 1952. 12p. diagrs. (ARC R & M 2421; ARC 9401. Formerly Department of Scientific Research and Experiment, Admiralty SRE/Airflow/29)

An error in the well-known work by Schlichting is corrected, and it is shown that the integral equation derived can be solved analytically. The main result is that for a plane rectangular wing of aspect ratio A, the lift coefficient is less than that for an infinite plane wing by a factor $1 - \frac{1}{2A\sqrt{M^2 - 1}}$ where M is the Mach number of the undisturbed stream. It is shown that the analytical solution can be extended to plane trapezoidal wings of any cutting-off angle.

Aeronautical Research Council (Gt. Brit.)
THE VALIDITY OF FULL-SCALE PROPELLER BRAKING TESTS IN THE R. A. E. 24-FT WIND TUNNEL. A. B. Haines and R. J. Monaghan. 1952. 9p. diagrs., 2 tabs. (ARC R & M 2473; ARC 10,309. Formerly RAE Tech. Note Aero 1851)

During tests at negative pitch air flow through the working section is considerably disturbed. To check the effect of tunnel interference, tests were made in both the 5-foot and 24-foot wind tunnels. Tests also provided information on Reynolds number effects and solidity. It was concluded that the effects of tunnel interference can be allowed for by a correction to J. Over the range of reliable measurements this additive correction decreases with J, becoming negligible for $J > 1.6$. For the tests an increase in Reynolds number had no appreciable effect on negative thrust. Correcting for a 2:1 increase in solidity by treating thrust and power as proportional to solidity may overestimate negative thrust for a given power by 30 percent.

SUPERSONIC DIFFUSERS. J. Lukasiewicz. 1952. 30p. diagrs., photos., 3 tabs. (ARC R & M 2501; ARC 10,110. Formerly RAE Gas 8)

Various possible types of supersonic diffuser are considered theoretically and the available experimental evidence is reviewed. The most obvious type of an efficient supersonic diffuser is the reversed supersonic nozzle. A stability criterion for the reversed supersonic nozzle is developed, which shows that the contraction between the entry and the throat is so limited that if a normal shock at entry is to be avoided such a diffuser is of little practical use unless an artificial means of inducing and maintaining the less stable flow can be found. Test results of simple pitot entries show that, in the absence of the boundary layer, the one-dimensional theory holds for normal shocks. Since their efficiency is high for Mach number up to about 1.5, diffusers with normal shock at entry are quite satisfactory in this velocity range. The mechanism of the shock wave and boundary-layer interaction is considered. When normal shocks occur in the presence of the boundary layer, as in annular pitot entries and diffusers for supersonic wind tunnels, their compression efficiency is appreciably lower than the theoretical one. For very high velocities, exceeding $M = 2.5$, the multishock diffuser is practicable and offers high theoretical efficiency. The efficiencies of this type of diffuser are examined and shown to exceed 90 percent up to $M = 3.0$ for designs having three or four oblique shocks. Various geometrical arrangements are considered from the point of view of reduction of frontal area for a given mass flow, and improvements on the single focused wave system are obtained. The high performance of multishock diffusers is confirmed by Oswatitsch's tests at Göttingen, the results of which are here summarized. The operation of supersonic diffusers at other than the design Mach number is briefly considered.

NOTE ON THE FRISE AILERON. H. H. B. M. Thomas and E. R. Crabbe. 1952. 16p. diagrs. (ARC R & M 2502; ARC 10,213. Formerly RAE Aero 2163)

In spite of its well known disadvantages the Frise aileron is still used and can yield a good aileron control when the balance required is not very close. There appears to be, therefore, a need for some means of estimating the hinge-moment characteristics of this type of aileron. The present note, besides giving a general discussion of the characteristics of Frise ailerons, includes a method of estimating the hinge moment from the hinge moment of the unbalanced ailerons. Means of improving the hinge moment characteristics, avoiding oscillation, and increasing the rolling power of Frise ailerons are also discussed. These include the use of differentially geared tabs and slats attached to the wing or the aileron.

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL TESTS ON THE SPOILING EFFECTS OF ENGINE COOLING GILLS ON RADIAL AIR-COOLED INSTALLATIONS ON A WING. J. Seddon and J. A. Kirk. 1952. 26p. diagrs., 6 tabs. (ARC R & M 2558; ARC 5659. Formerly RAE Aero 1724)

Spoiling drag associated with fully open gills at high C_L can be very large if the gill exit is nearer to the wing leading edge than about 10 percent of the local wing chord; but the effect diminshes rapidly as this distance is increased. The drag due to spoiling is reduced if the cooling air is kept away from the nacelle-wing junction by emitting it at specified regions around the exit, preferably at the bottom where the lift is a minimum. Larger gill angles would be needed to satisfy maximum-flow requirements in this way. The return-flow cooling system, with nose exit, shows no evidence of large spoiling drag at high cooling flow. The data obtained might be useful for estimating effects of other forms of discharge of low-energy air in front of a wing leading edge.

Aeronautical Research Council (Gt. Brit.)
THE PRODUCTION OF LIFT INDEPENDENTLY OF INCIDENCE - THE THWAITES FLAP, PARTS I AND II. B. Thwaites. 1952. 20p. diagrs. (ARC R & M 2611. Formerly ARC 10,100; FM 1020; Perf. 252; ARC 11,023; FM 1176, Perf. 378)

In Part I of this paper, the possibility of obtaining lift on a body in a uniform stream independently of the incidence is discussed, and a practical method which obtains this effect if given. It is shown that a small thin "flap" which may be moved about a well-rounded trailing edge through which, for example, continuous suction is applied will produce circulation about the airfoil. A necessary feature of this method is the prevention of separation of flow by boundary-layer suction, which is also used to reduce substantially the width of the wake. The method uses principles quite different from those which have been proposed in the past for obtaining increased lift on airfoils. The practical applications of the device are briefly discussed, and some interesting consequences pointed out. It will, for instance, be possible to fly with an airfoil always at zero incidence. Again, the stall in which the flow separates from near the leading edge may be completely avoided, for as the circulation and lift increase, the incidence may be decreased so that severe adverse velocity gradients occur nowhere but near the trailing edge.

In Part II of the paper, a report is given of a preliminary experiment which was set up to investigate whether the theoretical predictions made about the efficacy of the flap were largely confirmed. A wholly porous circular cylinder was fitted with the flap and measurements were made of the pressure distribution round the cylinder for various positions of the flap. These observations showed that for angular deflection of the flap of less than 20°, about 85 percent of the theoretical value of C_L was realized: a maximum C_L of about 5.6 was obtained. These results are taken to show that the physical principles of Part I are sound and that the Thwaites flap does, in fact, enable lift to be generated independently of incidence.

Aeronautical Research Council (Gt. Brit.)
TANK TESTS ON A HULL WITH THE MAIN STEP FAIRED IN PLANFORM AND ELEVATION. D. I. T. P. Llewelyn-Davies. 1952. 36p. diagrs., photos., 4 tabs. (ARC R & M 2708; ARC 8807. Formerly RAE Aero 2029)

Tank tests were required to find out whether the water characteristics of a hull with a main step, faired in both plan form and elevation, were comparable with those of a hull with a conventional Vee or transverse step. Stability diagrams and spray and resistance characteristics were obtained over a large range of loadings ($C_{\Delta 0} = 0.616$ to $C_{\Delta 0} = 1.440$). The fully faired step offers more possibility of designing a longitudinally stable flying boat hull than does the conventional transverse or Vee step, but a hull with such a step is 5 to 10 percent less efficient hydrodynamically except at high speed. In order to avoid running too fine at high speed, it is recommended that the center of gravity should not be more than 0.46b ahead of the

apex of the step. The modification to the step plan form makes little difference to the main spray characteristics, but increase in all-up-weight reduces wing, tail plane and propeller clearances. The effect of increase in load on the porpoising stability characteristics is to raise both limits, with a tendency for the upper limit to rise more rapidly, but less regularly, than the lower limit. The free-to-trim attitudes also rise with increase in all-up-weight. The planing efficiency of the hull increases with increase of load, especially at high speeds. There is evidence of a second resistance hump at high speeds and also of a critical variation of planing efficiency with attitude under similar conditions.

Royal Aircraft Establishment (Gt. Brit.)
CHARTS OF THE WAVE DRAG OF WINGS AT ZERO LIFT. T. Lawrence. January 1952. 18p. diagrs. (RAE Tech. Note Aero 2139)

Theoretical calculations of the wave drag at supersonic speeds of nonlifting wings of double wedge and biconvex section are reviewed, and the best method of presenting the results considered. Using this method, a representative selection of the available numerical evaluations of the theory is presented. These should be of value for wing drag estimation purposes.

SPECTRAL ENERGY DISTRIBUTION IN RADIATION DUE TO ENCOUNTERING SHOCK WAVES. (Répartition spectrale énérgetique dans la Lumière émise lors de la Recontre d'Ondes de Choc). A. Michel-Levy, H. Muraour and E. Vassy. April 1952. 19p. diagrs., photos. (Trans. from Revue d'Optique Theorique et Instrumentale, 1941, p.149-160).

This report deals with the determination of the energy distribution in a continuous spectrum obtained at the encounter with shock waves in the atmosphere of various gases: argon, helium, oxygen, etc. The reference source is the positive crater of a carbon arc. Various regions of the gas chamber were explored. The radiation is not that of a black body. The present status of the theory of continuous spectra offers no possibility for interpreting this phenomenon.

THE STRESS-STROKE DIAGRAM OF AIRPLANE SHOCK ABSORBER STRUTS. THIRD PARTIAL REPORT - THE LANDING IMPACT OF OLEO-PNEUMATIC SHOCK ABSORBERS. (Zur kenntnis der Kraftwegdiagramme von Flugzeugfederbeinen, 3. Teilbericht: Der Landestoss von Ölluftfederbeinen). K. Schlaefke. April 1952. 15p. diagrs., 3 tabs. (Trans. from Aerodynamische Versuchsanstalt Göttingen E.V., Technische Berichte, v. 11, no. 5, 1944, p. 137-141).

The stress-stroke diagram of an oleo-pneumatic leg under the first impact at landing can be obtained by superposing onto the diagram of the undamped compressed air leg, the damping diagram according to the second approximate method described in the preceeding partial report. The maximum stroke, maximum stress, and efficiency to be expected for divers damping, lift coefficients, and heights of drop are computed and represented diagrammatically for practical use. Lastly, it is indicated how the newly introduced damping factor for oleo-pneumatic legs can be determined by experiment.

ON THE RECIPROCAL EFFECTS BETWEEN SHOCK ABSORBER STRUT AND TIRE AT LANDING IMPACT OF AIRPLANE UNDERCARRIAGES. (Zur Kenntnis der Wechselwirkungen zwischen Federbein und Reifen beim Landestoss von Flugzeugfahrewerken). K. Schlaefke. May 1952. 18p. diagrs., 3 tabs. (Trans. from Aerodynamische Versuchsanstalt Göttingen E. V., Technische Berichte, v. 10, no. 11, 1943, p. 363-367).

This report deals with the reciprocal effects between shock-absorber strut and tire due to impact at landing. It was found that the tire reaches its maximum springing earlier than the strut and that at the first instant of landing impact the energy is taken up solely by the tire. The results are represented in diagrams which can be used for the conversion of experimental data to other combinations of tires and shock-absorber struts.

CURRENT NACA REPORTS

NACA Rept. 1025

EXPERIMENTAL AND THEORETICAL STUDIES OF AREA SUCTION FOR THE CONTROL OF THE LAMINAR BOUNDARY LAYER ON AN NACA 64A010 AIRFOIL. Albert L. Braslow, Dale L. Burrows, Neal Tetervin and Fioravante Visconti. 1951. ii, 19p. diagrs., photos. (NACA Rept. 1025. Formerly TN 1905; TN 2112)

Low-turbulence wind-tunnel tests were made of an NACA 64A010 airfoil section having a porous surface to investigate continuous suction as a means of controlling the laminar boundary layer. Full-chord laminar flow and large net reductions in drag were obtained up to a Reynolds number of approximately 20×10^6. It seems likely from the experimental results and a related theoretical analysis that attainment of full-chord laminar flow by means of continuous suction through a porous surface will be possible at any value of the Reynolds number provided that the airfoil surfaces are maintained sufficiently smooth and fair and provided that outflow of air through the surface is prevented.

NACA Rept. 1029

COMPRESSIVE STRENGTH OF FLANGES. Elbridge Z. Stowell. 1951. 14p. diagrs., tab. (NACA Rept. 1029. Formerly TN 2020)

The maximum compressive stress carried by a hinged flange is computed from a deformation theory of plasticity combined with the theory for finite deflections for this structure. The computed stresses agree well with those found experimentally. Empirical observation indicates that the results will also apply fairly well to the more commonly used flanges which are not hinged.

NACA Rept. 1030

INVESTIGATION OF SEPARATION OF THE TURBULENT BOUNDARY LAYER. G. B. Schubauer and P. S. Klebanoff, National Bureau of Standards. 1951. 20p. diagrs., photos., 8 tabs. (NACA Rept. 1030. Formerly TN 2133)

An investigation was conducted on a turbulent boundary layer near a smooth surface with pressure gradients sufficient to cause flow separation. The Reynolds number was high, but speeds were entirely within the incompressible flow range. The investigation consisted of measurements of mean flow, three components of turbulence intensity, turbulent shearing stress, and correlations between two fluctuation components at a point and between the same component at different points. Results are given in the form of tables and graphs. The discussion deals first with separation and then with the more fundamental question of basic concepts of turbulent flow.

NACA Rept. 1035

ANALYSIS OF MEANS OF IMPROVING THE UNCONTROLLED LATERAL MOTIONS OF PERSONAL AIRPLANES. Marion O. McKinney, Jr. 1951. ii, 9p. diagrs., 3 tabs. (NACA Rept. 1035. Formerly TN 1997)

A theoretical analysis of means of improving the uncontrolled lateral motions of personal airplanes is presented. The purpose of this analysis was to determine whether such airplanes could be made capable of flying uncontrolled for an indefinite period of time without getting into a dangerous attitude and for a reasonable period of time without deviating excessively from the original course.

NACA Rept. 1037

GENERAL METHOD AND THERMODYNAMIC TABLES FOR COMPUTATION OF EQUILIBRIUM COMPOSITION AND TEMPERATURE OF CHEMICAL REACTIONS. Vearl N. Huff, Sanford Gordon and Virginia E. Morrell. 1951. ii, 57p., 45 tabs. (NACA Rept. 1037. Formerly NACA TN 2113, TN 2161)

A rapidly convergent successive approximation process is described that simultaneously determines both composition and temperature resulting from a chemical reaction. This method is suitable for use with any set of reactants over the complete range of mixture ratios as long as the products of reaction are ideal gases. An approximate treatment of limited amounts of liquids and solids is also included. This method is particularly suited to problems having a large number of products of reaction and to problems that require determination of such properties as specific heat or velocity of sound of a dissociating mixture. The method presented is applicable to a wide variety of problems that include (1) combustion at constant pressure or volume; and (2) isentropic expansion to an assigned pressure, temperature, or Mach number. Tables of thermodynamic functions needed with this method are included for 42 substances for convenience in numerical computations.

NACA Rept. 1038

WIND-TUNNEL INVESTIGATION OF AIR INLET AND OUTLET OPENINGS ON A STREAMLINE BODY. John V. Becker. 1951. ii, 21p. diagrs., photos., 3 tabs. (NACA Rept. 1038. Formerly ACR, November 1940)

Air inlet openings at the nose of a streamline body and outlets at the tail and at the 21-percent and 63-percent stations of the body were investigated with the objective of developing low-drag high-critical-speed configurations. Drag, pressure-distribution, and boundary-layer measurements were made. Inlet and outlet opening shapes were found which caused no increase in drag over that of the basic streamline body to which the openings were applied. The critical Mach number of the ducted body was also equal to that of the basic body over a wide range of internal air flow rates.

NACA Rept. 1042

SOME EFFECTS OF NONLINEAR VARIATION IN THE DIRECTIONAL-STABILITY AND DAMPING-IN-YAWING DERIVATIVES ON THE LATERAL STABILITY OF AN AIRPLANE. Leonard Sternfield. 1951. ii, 9p. diagrs., tab. (NACA Rept. 1042. Formerly TN 2233)

The effect of nonlinear stability derivatives on the lateral stability of an airplane is analyzed. Motions are calculated on the assumption that the values of the directional-stability derivative and the damping-in-yawing derivative are functions of the angle of sideslip. The application of the Laplace transform to the calculation of an airplane motion when certain types of nonlinear derivatives are present is described in detail.

NACA Rept. 1047

THE STABILITY OF THE COMPRESSION COVER OF BOX BEAMS STIFFENED BY POSTS. Paul Seide and Paul F. Barrett. 1951. ii, 16p. diagrs., 3 tabs. (NACA Rept. 1047. Formerly TN 2153)

An investigation is made of the buckling of the compression cover of post-stiffened box beams subjected to end moments. Charts are presented for the determination of the minimum post axial stiffnesses and the corresponding compressive buckling loads required for the compression cover to buckle with nodes through the posts. Application of the charts to design and analysis and the limitations of their use are discussed.

NACA Rept. 1049

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF VERTICAL-TAIL SIZE AND LENGTH AND OF FUSELAGE SHAPE AND LENGTH ON THE STATIC LATERAL STABILITY CHARACTERISTICS OF A MODEL WITH 45° SWEPTBACK WING AND TAIL SURFACES. M. J. Queijo and Walter D. Wolhart. 1951. ii, 29p. diagrs., photos., 4 tabs. (NACA Rept. 1049. Formerly TN 2168)

Results are presented of an investigation to determine the effects of vertical-tail size and length and of fuselage shape and length on the lateral-static stability derivatives of a midwing airplane model with 45° sweptback wing and tail surfaces. Interference between the various model components also is evaluated.

NACA Rept. 1052

A SUMMARY OF LATERAL-STABILITY DERIVATIVES CALCULATED FOR WING PLAN FORMS IN SUPERSONIC FLOW. Arthur L. Jones and Alberta Alksne. 1951. ii, 35p. diagrs., 3 tabs. (NACA Rept. 1052)

Values of the lateral-stability derivatives for wings at supersonic speeds, calculated using the linearized theory for compressible flow, are presented in the form of design charts showing the variations of the derivatives with Mach number and aspect ratio for six plan forms. Limitations in the applicability and availability of the lateral-stability derivatives are discussed.

NACA Rept. 1059

A BIHARMONIC RELAXATION METHOD FOR CALCULATING THERMAL STRESS IN COOLED IRREGULAR CYLINDERS. Arthur G. Holms. 1952. ii, 19p. diagrs., 4 tabs. (NACA Rept. 1059. Formerly TN 2434)

A numerical method was developed for calculating thermal stresses in irregular cylinders cooled by one or more internal passages. The use of relaxation methods and elementary methods of finite differences was found to give approximations to the correct values when compared with previously known solutions for concentric circular cylinders possessing symmetrical and asymmetrical temperature distributions.

NACA Rept. 1060

DETAILED COMPUTATIONAL PROCEDURE FOR DESIGN OF CASCADE BLADES WITH PRESCRIBED VELOCITY DISTRIBUTIONS IN COMPRESSIBLE POTENTIAL FLOWS. George R. Costello, Robert L. Cummings and John T. Sinnette, Jr. 1952. ii, 14p. diagrs., 9 tabs. (NACA Rept. 1060. Formerly TN 2281)

A detailed step-by-step computational outline is presented for the design of cascade blades having a prescribed velocity distribution on the blade in a potential flow of the usual compressible fluid. This outline is based on the assumption that the magnitude of the velocity in the flow of the usual compressible nonviscous fluid is proportional to the magnitude of the velocity in the flow of a compressible nonviscous fluid with linear pressure-volume relation. The computational procedure includes several ways of adjusting the prescribed velocity to satisfy the restriction imposed by the method. Tables of coefficients are given for evaluating the necessary integrals, including the determination of the harmonic conjugate. Numerical examples are included.

NACA Rept. 1061

EFFECT OF INITIAL MIXTURE TEMPERATURE ON FLAME SPEED OF METHANE-AIR, PROPANE-AIR AND ETHYLENE-AIR MIXTURES. Gordon L. Dugger. 1952. ii, 12p. diagrs., photo., 3 tabs. (NACA Rept. 1061. Formerly TN 2170; TN 2374)

Flame speeds based on the outer edge of the shadow cast by the laminar Bunsen cone were determined as functions of composition for methane-air mixtures at initial mixture temperatures ranging from -132° to 342° C and for propane-air and ethylene-air mixtures at initial mixture temperatures ranging from -73° to 344° C. The data showed that maximum flame speed increased with temperature at an increasing rate. The percentage change in flame speed with change in initial temperature for the three fuels followed the decreasing order, methane, propane, and ethylene. Empirical equations were determined for maximum flame speed as a function of initial temperature over the temperature range covered for each fuel. For each fuel it was found that, with a fixed parallel-beam shadowgraph system, the ratio of flame speed based on the outer edge of the shadow cast by the flame cone to flame speed based on the inner edge of the shadow was a constant, independent of temperature or composition. The flame speed of propane-air flames was independent of tube diameter from 10 to 22 millimeters or stream-flow Reynolds number from 1500 to 2100. The observed effect of temperature on flame speed for each of the fuels was reasonably well predicted by either the thermal theory as presented by Semenov or the square-root law of Tanford and Pease. The importance of active radicals in flame propagation was indicated by a simple linear relation between maximum flame speed and equilibrium radical concentrations for all three fuels.

NACA TN 2643

SPAN LOAD DISTRIBUTIONS RESULTING FROM ANGLE OF ATTACK, ROLLING, AND PITCHING FOR TAPERED SWEPTBACK WINGS WITH STREAMWISE TIPS. SUPERSONIC LEADING AND TRAILING EDGES. John C. Martin and Isabella Jeffreys. July 1952. 143p. diagrs., 6 tabs. (NACA TN 2643)

On the basis of the linearized supersonic-flow theory the span load distributions resulting from constant angle of attack, from steady rolling, and from steady pitching were calculated for a series of thin sweptback tapered wings with streamwise tips and with supersonic leading and trailing edges. The results are valid for the Mach number range for which the Mach line from either wing tip does not intersect the remote half-wing. The results of the analysis are presented as a series of design charts. Some illustrative variations of the spanwise distributions of circulation with the various design parameters are also presented.

NACA TN 2656

A BLADE-ELEMENT ANALYSIS FOR LIFTING ROTORS THAT IS APPLICABLE FOR LARGE INFLOW AND BLADE ANGLES AND ANY REASONABLE BLADE GEOMETRY. Walter Castles, Jr. and Noah C. New, Georgia Institute of Technology. July 1952. 63p. diagrs., 7 tabs. (NACA TN 2656)

A blade-element analysis for lifting rotors is presented which is applicable for large inflow and blade angles and any reasonable blade geometry and should therefore be useful for convertaplane as well as helicopter calculations. Simple approximate relations between rotor thrust and flight-path velocity components and rotor blade angles, torque, and in-plane forces are derived and these solutions, based on the assumption of a triangular distribution of blade circulation and a parabolic variation of profile drag with lift, are sufficiently accurate for preliminary calculations and determination of equilibrium angle of attack and lateral tilt of the tip-path plane. More exact blade-element equations are then derived for the relations between thrust and flight-path velocity components and equilibrium blade angles, torque, and in-plane forces and moments.

NACA TN 2675

MEASUREMENTS OF FLYING QUALITIES OF AN F-47D-30 AIRPLANE TO DETERMINE LATERAL AND DIRECTIONAL STABILITY AND CONTROL CHARACTERISTICS. R. Fabian Goranson and Christopher C. Kraft, Jr. July 1952. 61p. diagrs., photos., 2 tabs. (NACA TN 2675)

Tests have been made of the flying qualities of an F-47D-30 airplane to determine the lateral and directional stability and control characteristics. Data are also presented of the aileron hinge-moment characteristics.

NACA TN 2715

THE THEORETICAL CHARACTERISTICS OF TRIANGULAR-TIP CONTROL SURFACES AT SUPERSONIC SPEEDS. MACH LINES BEHIND TRAILING EDGES. Julian H. Kainer and Mary Dowd King. July 1952. 76p. diagrs., 4 tabs. (NACA TN 2715)

By means of linearized theory, generalized expressions in closed form have been obtained for the characteristics due to control-surface deflection $\left(C_{L_\delta},\ C_{l_\delta},\ C_{m_\delta},\ \text{and}\ C_{h_\delta}\right)$ and due to wing angle of attack $\left(C_{h_\alpha}\right)$ for wing plan forms having triangular-tip control surfaces at supersonic speeds. The analysis considers wing trailing-edge sweep, control-surface geometry, and Mach number for the deflection characteristics. For C_{h_α}, the effects of wing leading-edge sweep and aspect ratio are also included. The analysis is limited to configurations where the trailing edges are supersonic and where the innermost Mach lines from the leading edge of the control-surface root chord do not intersect the wing root chord.

NACA TN 2737

PLASTIC STRESS-STRAIN RELATIONS FOR COMBINED TENSION AND COMPRESSION. Joseph Marin and H. A. B. Wiseman, Pennsylvania State College. July 1952. 61p. diagrs., photos., 2 tabs. (NACA TN 2737)

Plastic stress-strain relations for biaxial tension-compression principal stresses were determined for a 14S-T4 aluminum alloy. Constant-stress-ratio tests provided control data and information on the influence of biaxial stresses on the yield strength of the material. Variable-stress-ratio tests were made to determine whether the deformation or flow theory agrees better with actual plastic stress-strain relations and special tests were conducted to check the validity of various assumptions made in these theories.

NACA TN 2739

NUMERICAL DETERMINATION OF INDICIAL LIFT AND MOMENT FUNCTIONS FOR A TWO-DIMENSIONAL SINKING AND PITCHING AIRFOIL AT MACH NUMBERS 0.5 AND 0.6. Bernard Mazelsky and Joseph A. Drischler. July 1952. 37p. diagrs., 4 tabs. (NACA TN 2739)

Approximate values for the indicial lift and moment functions on a sinking and pitching airfoil are calculated for Mach numbers 0.5 and 0.6. The indicial lift function associated with an airfoil penetrating a sharp-edge gust is also determined approximately at Mach numbers 0.5, 0.6, and 0.7.

NACA TN 2741

INVESTIGATION OF THE INFLUENCE OF FUSELAGE AND TAIL SURFACES ON LOW-SPEED STATIC STABILITY AND ROLLING CHARACTERISTICS OF A SWEPT-WING MODEL. John D. Bird, Jacob H. Lichtenstein and Byron M. Jaquet. July 1952. 18p. diagrs., photo. (NACA TN 2741. Formerly RM L7H15)

Results are presented of a wind-tunnel investigation to determine influence of the fuselage and tail on static stability and rotary derivatives in roll of a model having 45° sweptback wing and tail surfaces. The wing alone and the model without the horizontal tail showed marginal longitudinal stability near maximum lift. The longitudinal stability of the complete model was satisfactory. The vertical tail produced larger increments of rate of change of lateral-force and yawing-moment coefficients with wing-tip helix angle than the fuselage or the horizontal tail.

NACA TN 2744

PRACTICAL CALCULATION OF SECOND-ORDER SUPERSONIC FLOW PAST NONLIFTING BODIES OF REVOLUTION. Milton D. Van Dyke. July 1952. 62p. diagrs., 2 tabs., 2 charts. (NACA TN 2744)

Calculation of second-order supersonic flow past bodies of revolution at zero angle of attack is described in detail, and reduced to routine computation. Use of an approximate tangency condition is shown to increase the accuracy for bodies with corners. Tables of basic functions and standard computing forms are presented. The procedure is summarized so that one can apply it without necessarily understanding the details of the theory. A sample calculation is given, and several examples are compared with solutions calculated by the method of characteristics.

NACA TN 2745

INFLUENCE OF CHEMICAL COMPOSITION ON RUPTURE TEST PROPERTIES AT 1500° F OF FORGED CHROMIUM-COBALT-NICKEL-IRON BASE ALLOYS. J. W. Freeman, J. F. Ewing and A. E. White, University of Michigan. July 1952. 69p. diagrs., photos., 2 tabs. (NACA TN 2745)

Sixty-two alloys involving systematic individual variations of 10 elements present in a forged chromium-cobalt-nickel-iron base alloy in the solution-treated and aged condition and simultaneous variation of molybdenum, tungsten, and columbium were rupture tested at 1500° F. It was found that the elements can be varied individually between quite wide limits without significantly changing the rupture properties. The results were similar to those previously obtained at 1200° F (NACA Rept. 1058) except that increased chromium was not beneficial at 1500° F and the saturation effect for molybdenum and tungsten did not occur at 1200° F.

NACA TN 2746

PREVIEW OF BEHAVIOR OF GRAIN BOUNDARIES IN CREEP OF ALUMINUM BICRYSTALS. F. N. Rhines and A. W. Cochardt, Carnegie Institute of Technology. July 1952. 40p. diagrs., photos. (NACA TN 2746)

Gliding of aluminum bicrystals along their mutual boundary was studied during creep tests at 200° to 650° C and 1 to 100 psi. The direction of motion depends only upon the direction of maximum resolved shear stress in the boundary plane. The magnitude of the motion increases with magnitude of resolved shear stress, temperature, and degree of mismatch between orientations of the crystals. Gliding rate is cyclic and for each temperature there is a stress below which gliding does not occur. At low temperature and small orientation difference an induction period precedes gliding. Gliding operates in a relatively thick zone of crystalline metal on both sides of the boundary. Portions of the grains away from the boundary degenerate into blocks that move with respect to each other, parallel to the tension axis, and that rotate about octahedral axes of the original crystal.

NACA TN 2750

MATRIX AND RELAXATION SOLUTIONS THAT DETERMINE SUBSONIC THROUGH FLOW IN AN AXIAL-FLOW GAS TURBINE. Chung-Hua Wu. July 1952. 65p. diagrs., 7 tabs. (NACA TN 2750)

A method recently developed for determining the steady flow of a nonviscous compressible fluid along a relative stream surface between adjacent blades in a turbomachine was applied to investigate subsonic through flow in a single-stage axial-flow gas turbine. For both incompressible and compressible flows, the variation in flow on the stream surface was determined by using both the relaxation and the matrix methods. In all solutions considered, convergence was obtained without difficulty. The compressibility of the gas and the radial twist of the stream surface had equally significant effects on the considerable amount of radial flow obtained. The results of these accurate calculations provide a basis for evaluation of simpler, more approximate methods for computing subsonic through flow in turbomachines.

NACA TN 2754

A METHOD OF SELECTING THE THICKNESS, HOLLOWNESS, AND SIZE OF A SUPERSONIC WING FOR LEAST DRAG AND SUFFICIENT BENDING STRENGTH AT SPECIFIED FLIGHT CONDITIONS. James L. Amick. July 1952. 38p. diagrs. (NACA TN 2754)

The method described, which is suitable for use in preliminary missile design, is based on simple beam theory and takes into account the effects of wing weight and type of skin thickness distribution. For cases in which the wing weight is negligible, a simplification of the general method gives the best lift-drag ratio consistent with the bending strength requirement of a given combination of plan form and profile shape at a given Mach number as a function of a single design parameter. An example of the application of the method to a diamond wing at Mach number 2.0, for a range of specified flight conditions, is presented.

NACA RM E52C31

TRUE AIRSPEED MEASUREMENT BY IONIZATION-TRACER TECHNIQUE. Bemrose Boyd, Robert G. Dorsch and George H. Brodie. July 1952. 37p. diagrs., photos. (NACA RM E52C31)

Ion bundles produced in a pulse-excited corona discharge are used as tracers with a radar-like pulse transit-time measuring instrument in order to provide a measurement of airspeed that is independent of all variables except time and distance. The resulting instrumentation need not project into the air stream and, therefore, will not cause any interference in supersonic flow. The instrument was tested at Mach numbers ranging from 0.3 to 3.8. Use of the proper instrumentation and technique results in accuracy of the order of 1 percent.

NACA RM E52E12

USE OF CHOKED NOZZLE TECHNIQUE AND EXHAUST JET DIFFUSER FOR EXTENDING OPERABLE RANGE OF JET-ENGINE RESEARCH FACILITIES. John H. Povolny. July 1952. 17p. diagrs. (NACA RM E52E12)

An investigation has been conducted to determine the increase in the useful ranges of flight conditions that may be obtained with a given jet-engine research facility when the choked nozzle technique or the exhaust jet diffuser, or both, are employed. This report describes these two methods, presents the considerations involved in their application, and gives typical results of their use as well as confirmation of the accuracy of data obtained by utilization of these techniques. The validity and accuracy of the choked nozzle technique and the associated area - pressure-differential thrust correction term were substantiated by turbojet-engine and exhaust-nozzle performance data covering a range of nozzle pressure ratios up to about 10. It was demonstrated by calculations for a typical turbojet engine installed in a typical altitude test facility that a considerable increase in the range of flight conditions that can be investigated may be obtained by use of the choked nozzle technique. It was also demonstrated that the range of facility exhaust pressures or exhauster flows may be increased by use of the exhaust jet diffuser.

BOUND AND TRAILING VORTICES IN THE LINEARISED THEORY OF SUPERSONIC FLOW, AND THE DOWNWASH IN THE WAKE OF A DELTA WING. A. Robinson and J. H. Hunter-Tod. 1952. 14p. diagrs. (ARC R & M 2409; ARC 11,296. Formerly *College of Aeronautics, Cranfield. Rept. 10*)

The field of flow round a flat airfoil at incidence can be regarded in linearized theory as the result of both bound and trailing vortices for supersonic as well as for low-speed flight. This leads to a convenient method, given the lift distribution over an airfoil, for calculating the flow round it at supersonic speeds. As an application of the results, the downwash is calculated in the wake of a delta wing lying within the Mach cone emanating from its apex. The downwash is found to be least just aft the trailing edge and is everywhere less than the downflow at the airfoil. It increases steadily to a limiting value which is attained virtually within two chord lengths of the trailing edge. The ratio of the downwash at any point in the wake to the downflow at the airfoil decreases with increasing Mach number and apex angle.

THE AERODYNAMIC DERIVATIVES WITH RESPECT TO SIDESLIP FOR A DELTA WING WITH SMALL DIHEDRAL AT ZERO INCIDENCE AT SUPERSONIC SPEEDS. A. Robinson and J. H. Hunter-Tod. 1952. 14p. diagrs. (ARC R & M 2410; ARC 11,322. Formerly College of Aeronautics, Cranfield. Rept. 12)

Expressions are derived for the sideslip derivatives on the assumptions of the linearized theory of flow for a delta wing with small dihedral flying at supersonic speeds. A discussion is included in the Appendix on the relation between two methods that have been evolved for the treatment of aerodynamic force problems of the delta wing lying within its apex Mach cone. When the leading edges are within the Mach cone from the apex, the pressure distribution and the rolling moment are independent of Mach number but dependent on aspect ratio. When the leading edges are outside the apex Mach cone, the nondimensional rolling derivative is, in contrast to the other case, dependent on Mach number and independent of aspect ratio; the other derivatives and the pressure, however, are dependent on both variables.

USE OF NEGATIVE CAMBER IN THE TRANSONIC SPEED RANGE. W. F. Hilton. 1952. 5p. diagrs. (ARC R & M 2460. Formerly ARC 10,421; FM 1077; S & C 2100)

Certain difficulties are experienced when attempting free flight in the transonic speed range (0.8 to 1.2 of the speed of sound). These difficulties fall into two main classes: namely, (1) overcoming the somewhat high air resistance by means of improvements in engine design, and (2) balancing the aircraft for stable horizontal flight. The latter problem is considered in this paper. Changes of trim are caused by sudden loss of wing lift in the transonic range, which decreases the downwash over the tail, and possibly results in an uncontrollable nose-heavy dive. The use of negative wing camber for minimizing these effects is suggested, and the suggestion is found to be supported by wind-tunnel experiments.

EXPERIMENTS ON THIN TURNING VANES. C. Salter. 1952. 29p. diagrs., photo., 9 tabs. (ARC R & M 2469. Formerly ARC 10,039; TP 164)

The experiments recorded in this paper refer to a variety of tests made on corner vanes (mainly thin curved plates) in a tunnel 1 foot square, with the object of indicating whether and to what extent they would be suitable for deflecting the air stream around the corners of return-flow type wind tunnels. It was found that the air stream could be turned very satisfactorily by the use of thin vanes and that the loss of head in a 90° corner was not as great as had been expected. Taking the pitch of the vanes to be the geometrical pitch in a direction perpendicular to the axis of the tunnel and the chord to be the distance between the centers of radii of the leading and trailing edges, the optimum ratio of pitch to chord for minimum loss was shown to be about 0.25. At that P/C ratio and Reynolds number of 2×10^{5}, based on chord length and air velocity of approach, the loss of total head in the corner was found to be 0.12 of the dynamic head, while in the region outside the boundary layer the minimum value was only 0.06. To ensure stability of the stream, a P/C ratio of 0.2 is recommended and it appears that, in order to maintain a thin boundary layer, the actual number of vanes in any one corner should be not less than say 15 to 20. A clean entry of the streamlines into the vane unit can be established by giving the leading-edge tangents an incidence of about 5° relative to the upstream axis of the tunnel. The minimum corner loss with 45° deflection was found to be about 0.05 of the dynamic head with a P/C ratio of roughly 0.4. A set of "Collar" vanes with splitters gave very satisfactory turning of the stream with a loss of head in the corner of 0.17 of the dynamic head, at a Reynolds number of 150,000, the corresponding figure in the region outside the boundary layer being 0.12. As the effect of the walls in assisting the deflection of the stream is so large it is suggested that the static-pressure distribution is as good a criterion as any of the effectiveness of the corner. Uniformity of static pressure over both upstream and downstream cross-section to within a short distance from the walls is a good test for the correct shape and setting of the vanes.

WIND-TUNNEL TESTS ON THE 30 PER CENT. SYMMETRICAL GRIFFITH AEROFOIL WITH EJECTION OF AIR AT THE SLOTS. N. Gregory, W. S. Walker and W. G. Raymer. 1952. 11p. diagrs. (ARC R & M 2475. Formerly ARC 10,097; FM 1018, Perf. 251)

It has been shown by Preston (1946) that ejection of air at the point of velocity discontinuity on a 16.2 percent thick Griffith suction airfoil prevents separation, and that if sufficient air is ejected, the drag is reduced. The present tests were undertaken to apply this principle to the 30 percent Griffith airfoil and to investigate the effect on lift by pressure-plotting the airfoil. Ejection of air was found to prevent separation, but about 66 percent more air was required than with suction. Three times the suction quantity of air, when ejected, reduced the drag to the low values associated with suction. At R = 0.96 million, the range of the tests was 0°-18° incidence and 0°-14° flap angle. At 18° incidence and 14° flap angle, a C_{NF} of 2.5 was obtained, giving approximately the same lift-curve slope as with suction. Above this angle of incidence, the pump capacity was not large enough for unseparated flow to be attained. With separation prevented, the pitching moments were the same as with suction, but the hinge moments were sensitive to small changes of blowing quantity. At R = 2.88 million, the pump capacity was insufficient to prevent a partial stall at 6° incidence as occurred with suction. Curves of C_{NF}, C_Q, C_M, C_H, C_D and velocity distribution when blowing are given, and comparisons are made with corresponding curves obtained with suction and with no suction. The same lift and pitching moments are obtained at any incidence with blowing and with suction, but the suction quantities are about 40 percent less than the blowing quantities. The hinge moments are greatly different with blowing, and increase of the normal force.

THE EFFECT OF POINTED TIPS ON WING LOADING CALCULATIONS. V. M. Falkner. 1952. 4p. diagr., tab. (ARC R & M 2483. Formerly ARC 10,037; S & C 2063; Perf. 235)

The standard formulas for calculation of wing loading by vortex lattice theory, which involve a sequence starting with $\sqrt{(1 - \eta^2)}$, are not strictly valid for pointed wing tips. On the other hand, the use of a sequence starting with $1 - \eta^2$ leads to overcorrection. By considering the mean of these two solutions for a delta wing, it is shown that the error introduced by the use of the standard sequence is small and is on the safe side as regards bending moments.

FLIGHT MEASUREMENTS OF THE PRESSURE DISTRIBUTION ON A TEMPEST WING UP TO A MACH NUMBER OF 0.8. K. Eyre. 1952. 15p. diagrs. (ARC R & M 2489; ARC 10,550. Formerly Hawker Aircraft, Ltd. Design Rept. 1131)

This investigation was to determine the effect of Mach number on the pressure distribution of the Hawker airfoil section as fitted to Tempest and Fury aircraft. The distributions show the typical supersonic flow conditions obtained over an airfoil of this type. The airfoil does not show any unusual characteristics and there are no large changes in pitching moment and position of the aerodynamic center below a Mach number of about 0.75. In all cases the favorable pressure gradient in front of the shock wave is fairly gradual, but changes rapidly at the shock wave. There is, however, no sign of a breakdown in flow at the trailing edge, where the distributions are similar for all values of Mach number. The values obtained for critical Mach number agree quite well with those given in the Royal Aeronautical Society data sheets. The variations of center-of-pressure position, pitching moment, and aerodynamic-center position are in quite good agreement with German wind-tunnel tests made on an approximately similar airfoil.

24-FT. WIND-TUNNEL TESTS ON A "PADDLE-BLADE" PROPELLER. A. B. Haines. 1952. 15p. diagrs. (ARC R & M 2493; ARC 10,308. Formerly RAE Aero 2172)

The report contains the results of tests made in the Royal Aircraft Establishment 24-foot tunnel on a de Havilland propeller having conventional Clark Y sections and the paddle-blade type of plan form. The report describes analyses of the results made both by single-radius and full-strip theory methods. The data provided will enable estimates to be made of the performance of paddle-blade propellers under various flight conditions and, in particular, will give a quantitative idea of the improvements to be expected for high power loadings, that is, beyond the stall. The principal general conclusions are: (1) Use of the same lift/drag data in eight radius strip theory calculations for both paddle-blade and normal propellers is justified. (2) The gains found in flight tests for paddle-blade propellers must be principally ascribed to the effects of NACA 16 series sections. (3) RAE charts based on single-radius data may be pessimistic in predicting the peak efficiencies of paddle propellers at high tip speed (by 1.5 to 2 percent for $M_T = 0.85$). (4) The mean stalling performance is better than would be expected even on an activity factor basis. This enables other design modifications, for example, thin roots, 16 series sections, etc. to be made to improve the top speed performance without causing serious losses at take-off or climb. (5) Therefore, the general conclusion is that use of the paddle type of plan form is fully justifiable even though it does not appear to offer any direct shock-stalling relief.

TESTS ON THREE EQUILATERAL TRIANGULAR PLATES IN THE COMPRESSED AIR TUNNEL.
R. Jones and C. J. W. Miles. 1952. 7p. diagrs., 4 tabs. (ARC R & M 2518. Formerly ARC 9973; Perf. 222)

The report gives C_L, C_D, and C_m on three equilateral triangular plates with sides 26, 36, and 47.8 inches. The object of the tests was to estimate the size of sweptback wings of that form, which can be tested in the compressed air tunnel without the application of excessive tunnel corrections. After applying the usual tunnel corrections and making small corrections due to dissymmetry in the models, it was found that C_L on the three models agreed if the results on the 36-inch and 47.8-inch models were multiplied by 1.01 and 1.05, respectively. Fair agreement was obtained on C_D for the three models. The mean position of the center of pressure is about 0.45 of the height of the triangle forward of the trailing edge.

THE YAWING VIBRATIONS OF AN AIRCRAFT.
J. Morris and G. S. Green. 1952. 11p. diagrs. (ARC R & M 2525; ARC 9482. Formerly RAE SME 4027)

This report gives a theoretical method for calculating the natural frequencies and modes of yawing vibration of a complete aircraft. The basic feature of the treatment is the replacement of the continuous mass system by one consisting of a finite number of discrete masses elastically interconnected. In the course of the analysis, use is made of the deflection coefficient artifice in the formation of the equations of motion, and the escalator process in their marshalling and numerical solution. The method has been applied to a single-engined fighter aircraft, for which the results of a resonance test were available. These results appear to be some 40 percent in excess of their calculated counterparts and no satisfactory explanation occurs to the authors to account for this incompatability.

AIRCRAFT LANDING GEAR: GROUND LOADS WHEN SPINNING-UP THE WHEELS AT TOUCH-DOWN. J. W. Blinkhorn. 1952. 13p. diagrs., 2 tabs. (ARC R & M 2588; ARC 11,627. Formerly RAE Tech. Note Mech. Eng. 16)

The investigation covers all combinations of landing speed, coefficient of friction between the tire and the ground, and harshness of landing, for any type of pneumatic tire and wheel unit. Particular attention has been given to landing speeds between 50 and 150 mph, coefficients of friction from 0 to 2.0, and landings giving vertical wheel accelerations of 1g, 2g, 3g, and 4g. It was found that for any landing, the vertical reaction, at any wheel which has just finished spinning up increases with increase in the moment of inertia of the wheel and tire unit, and the landing speed, and decreases with increase in the free tire radius, the aircraft weight, the time to reach the maximum vertical wheel reaction, and the coefficient of friction between the tire and the ground. It should be noted, of course, that there is a relation between the moment of inertia, the free tire radius and the aircraft weight - in general the free tire radius and the moment of inertia will increase with aircraft weight. For any wheel and tire unit, it is shown that there are various combinations of landing speed and coefficient of friction which cause the wheel spinning up to just cease at the same instant as the maximum vertical wheel reaction is reached, and except for very gentle landings, the maximum value of μ required is usually much less than 1.0.

THE SOLUTION BY LIFTING-LINE THEORY OF PROBLEMS INVOLVING DISCONTINUITIES.
V. M. Falkner. 1952. 23p. diagrs., 15 tabs. (ARC R & M 2592. Formerly ARC 10,922; S & C 2158; Perf. 366)

The report, which has been written as a preliminary to a later account of similar work in lifting-plane theory, describes how wing loading problems involving discontinuities are solved by lifting-line theory. The four discontinuities considered are (a) direction of leading or trailing edge, (b) incidence, (c) two-dimensional lift slope, and (d) chord. As the effects of the first are of minor importance in lifting-line theory, attention is mainly confined to the last three, the solution being based on the use of a few terms of a Fourier series in conjunction with special functions tabulated elsewhere. The work is limited to straight unyawed flight and includes lift, induced drag, and pitching, rolling, and yawing moments, all with or without deflected landing flaps and ailerons. The method of formation of the equations, and the solutions of a representative range of problems for a hypothetical wing, including loading due to incidence, symmetrical wing twist, uniform roll, and deflected flaps and ailerons, are fully described. An indication is given of how induced drag and yawing-moment calculations will later be simplified by the use of special derived functions. Absolute values of wing properties as given by lifting-line theory are usually too high, but the specification of correction factors for viscosity is beyond the scope of the report.

CALCULATED LOADINGS DUE TO INCIDENCE OF A NUMBER OF STRAIGHT AND SWEPT-BACK WINGS. V. M. Falkner. WITH APPENDIX. Doris Lehrian. 1952. 43p. diagrs., 43 tabs. (ARC R & M 2596. Formerly ARC 11,542; Perf. 449; S & C 2223)

In this report are collected together the calculated aerodynamic loadings due to incidence of a number of straight and sweptback wings. The calculations follow in the main the routine described previously in another report, but include additions concerned with induced camber and induced drag. An additional investigation is made of the effect of the NACA camber on the properties at zero lift of a rectangular wing of aspect ratio 6. A table is given of loading functions for use in auxiliary solutions when the wing plan has a discontinuity of direction at an arbitrary position along the span.

SPEEDS AND NORMAL ACCELERATIONS OF BOEING CLIPPER AIRCRAFT ON NORTH AND SOUTH ATLANTIC ROUTES. D. T. Jones. 1952. 14p. diagrs., 6 tabs. (ARC R & M 2633; ARC 11,640. Formerly RAE Structures 25)

This report presents results obtained from V-g recorders fitted to Boeing Clipper aircraft on the North and South Atlantic routes between September 1944 and May 1946. The records cover about 3,300 flying hours and show that the maximum speed recorded is 215 mph (I. A. S.) and the maximum upward and downward accelerations are 2.3g and -0.3g, respectively. The two main groups of records considered differ from one another not only in respect of route but also in seasonal conditions and in proportion of flights made in wartime. Therefore, differences between the results cannot be simply ascribed to differences of route. It appears from the analysis that the maximum speed likely to be attained in a large flying time is somewhat greater in one group (North Atlantic) than in the other (South Atlantic) and that the maximum accelerations on the other hand are likely to be less for the former than the latter.

NOTE ON THE CONDITION OF MATRICES. Olga Todd. September 6, 1949. 3p. (ARC 12,561; 0.833)

The object of this note is to establish the following theorem: let A be a real n x n nonsingular matrix and A' its transpose. Then AA' is more "ill-conditioned" than A. This result confirms an opinion expressed by Dr. L. Fox which he based on his practical experience. The term "condition of a matrix" has been used in vague senses. The most common measure of a matrix has been the size of its determinant: ill-conditioned matrices being those with small determinants. With this interpretation, the theorem is clearly correct. More adequate measures of the condition of a matrix have been proposed recently by John von Neumann and H. H. Goldstine and A. M. Turing.

A NOTE ON THE DESIGN OF A HIGH-SPEED WIND TUNNEL DRIVEN BY STEAM. T. R. Cave-Browne-Cave. September 15, 1949. 5p. diagrs. (ARC 12,577; TP 292)

A steam-driven supersonic wind tunnel has been designed for, and is being built by, the University College in Southampton. It has a 6 inch by 2-1/2 inch working section and will operate at a Mach number of 1.4 for a period of 3 minutes. Since it takes about 5 minutes for the boiler to return to pressure, a 3 minute test could be made every 8 minutes with this set-up. Because the boiler is already available at the school, this design permits a substantial saving in time and money. Another advantage will be the comparative lack of noise as compared with a drive using a compressor.

Royal Aircraft Establishment (Gt. Brit.)
THE RHEOLOGY OF LUBRICANT FILMS. PART 2. E. Bielak and E. W. J. Mardles. February 1952. 27p. diagrs. (RAE Chem. 480)

This report presents further results on the rheological properties of thin lubricant films (including greases) moving between surfaces, with special regard to the influence of the material of the surfaces on the rate of flow. The limitation of Amontons' law to pressures above 100 g/sq cm for lubricants is described in relation to the phenomenon of the "wringing" together or "striction" of surfaces at light pressures, especially with indifferent lubricants, when film rupture occurs early during the thinning of the film. The latent period, observed and first described by Hardy, during which friction changes occur has been measured for several lubricants at low pressures. Explanations of hydraulic "striction" and the "latent period" are suggested.

NACA Rept. 1040

SPECTRA AND DIFFUSION IN A ROUND TURBULENT JET. Stanley Corrsin and Mahinder S. Uberoi. 1951. ii, 21p. diagrs., photos. (NACA Rept. 1040. Formerly TN 2124)

In a round turbulent jet at room temperature, measurement of the shear correlation coefficient as a function of frequency (through band-pass filters) has given a rather direct verification of Kolmogroff's local-isotropy hypothesis. One-dimensional power spectra of velocity and temperature fluctuations, measured in unheated and heated jets, respectively, have been contrasted. Under the same conditions, the two corresponding transverse correlation functions have been measured and compared. Measurements have been made of the mean thermal wakes behind local (line) heat sources in the unheated turbulent jet, and the order of magnitude of the temperature fluctuations has been determined.

NACA Rept. 1048

A STUDY OF EFFECTS OF VISCOSITY ON FLOW OVER SLENDER INCLINED BODIES OF REVOLUTION. H. Julian Allen and Edward W. Perkins. 1951. ii, 13p. diagrs., photos. (NACA Rept. 1048. Formerly TN 2044)

The observed flow field about slender inclined bodies of revolution is compared with the calculated characteristics based upon potential theory. The comparison is instructive in indicating the manner in which the effects of viscosity are manifest. Based on this and other studies, a method is developed to allow for viscous effects on the force and moment characteristics of bodies. The calculated force and moment characteristics of two bodies of high fineness ratio are shown to be in good agreement, for most engineering purposes, with experiment.

NACA Rept. 1051

AN ANALYSIS OF BASE PRESSURE AT SUPERSONIC VELOCITIES AND COMPARISON WITH EXPERIMENT. Dean R. Chapman. 1951. ii, 23p. diagrs., photos. (NACA Rept. 1051. Formerly TN 2137)

The pressure on the base of an object travelling at supersonic velocity is investigated for both two-dimensional and axially-symmetric bodies. Inviscid-fluid flow is analyzed first and the result obtained that a strictly inviscid-fluid theory is not satisfactory. An approximate semiempirical theory for the base-pressure flow in a viscous fluid is then developed from a correlation of certain experiment data.

NACA Rept. 1055

COMPARISON OF THEORETICAL AND EXPERIMENTAL HEAT-TRANSFER CHARACTERISTICS OF BODIES OF REVOLUTION AT SUPERSONIC SPEEDS. Richard Scherrer. 1951. ii, 15p. diagrs., photo. (NACA Rept. 1055. Formerly RM A8L28; TN 1975; TN 2087; TN 2131; TN 2148)

An investigation of the three important factors that determine convective heat-transfer characteristics at supersonic speeds, location of boundary-layer transition, recovery factor, and heat-transfer parameter has been performed at Mach numbers from 1.49 to 2.18. The bodies of revolution that were tested had, in most cases, laminar boundary layers, and the test results have been compared with available theory. Boundary-layer transition was found to be affected by heat transfer. Adding heat to a laminar boundary layer caused transition to move forward on the test body, while removing heat caused transition to move rearward. These experimental results and the implications of boundary-layer-stability theory are in qualitative agreement. Theoretical and experimental values of the recovery factor, based on the local Mach number just outside the boundary layer, were found to be in good agreement for both laminar and turbulent boundary layers on both of the body shapes that were investigated. In general, values of the heat-transfer parameter (Nusselt number divided by the square root of the Reynolds number) as determined for both heated and cooled cones with uniform and nonuniform surface temperatures, were in good agreement with theory. It was also found that the theory for cones could be used to predict the values of heat-transfer parameter for a pointed body of revolution with large negative pressure gradients with good accuracy.

cient, and rate of roll due to aileron deflections on swept and unswept wings at subsonic and supersonic speeds. Some design considerations brought out by the results of this paper are discussed.

NACA TN 2751

A SIMPLE APPROXIMATE METHOD FOR CALCULATING SPANWISE LIFT DISTRIBUTIONS AND AERODYNAMIC INFLUENCE COEFFICIENTS AT SUBSONIC SPEEDS. Franklin W. Diederich. August 1952. 63p. diagrs., tab. (NACA TN 2751)

Several approximate methods for calculating lift distributions at subsonic speeds are combined and extended to form a simple step-by-step procedure for calculating symmetric and antisymmetric lift distributions on swept and unswept wings. The extension of the method to the calculation of aerodynamic influence coefficients and of spanwise moment distributions is indicated.

NACA TN 2752

A STUDY OF THE STABILITY OF THE LAMINAR BOUNDARY LAYER AS AFFECTED BY CHANGES IN THE BOUNDARY-LAYER THICKNESS IN REGIONS OF PRESSURE GRADIENT AND FLOW THROUGH THE SURFACE. Neal Tetervin and David A. Levine. August 1952. 83p. diagrs., tab. (NACA TN 2752)

Calculations made by the Schlichting method for the computation of laminar-boundary-layer velocity profiles and the Lin method for the computation of their critical Reynolds numbers demonstrate that in a region of falling pressure on an impervious surface an increase in boundary-layer thickness can cause the velocity profile shape to be changed enough by the increase in effective pressure gradient so that the ratio of the local critical Reynolds number to the local boundary-layer Reynolds number is increased. Similar effects occur when there is flow through the surface; in this case the effects depend on the effective flow through the surface as well as on the effective pressure gradient. These calculations suggest that the disturbing effect of roughness particles can be decreased by a sufficient increase in boundary-layer thickness without a decrease in stability.

NACA TN 2753

EFFECTS OF MACH NUMBER VARIATION BETWEEN 0.07 AND 0.34 AND REYNOLDS NUMBER VARIATION BETWEEN 0.97×10^6 AND 8.10×10^6 ON THE MAXIMUM LIFT COEFFICIENT OF A WING OF NACA 64-210 AIRFOIL SECTIONS. James E. Fitzpatrick and William C. Schneider. August 1952. 34p. diagrs., photos., tab. (NACA TN 2753)

The effects of Mach number and Reynolds number on the maximum lift coefficient of a wing of NACA 64-210 airfoil sections are presented. The wing was tested with and without partial-span and full-span split flaps deflected 60°. Peak maximum lift coefficients were measured at Mach numbers between 0.12 and 0.20, depending on the Reynolds number range and flap configuration.

NACA TN 2755

ANALYSIS OF LANDING-GEAR BEHAVIOR. Benjamin Milwitzky and Francis E. Cook. August 1952. 98p. diagrs., photo., 3 tabs. (NACA TN 2755)

The behavior of the conventional oleo-pneumatic landing gear during impact is analyzed. The applicability of the analysis to actual landing gears is established by comparing calculated results with drop-test data. In addition to the more exact treatment, studies are made to determine the effects of variations in such parameters as the force-deflection characteristics of the tire, the orifice discharge coefficient, and the polytropic exponent for the air-compression process in the shock strut, which may not be known accurately in practical design problems. An investigation is also made to determine the extent to which representation of the system can be simplified and still yield useful results. Generalized solutions for the behavior of a simplified system, which may be useful in preliminary design, are presented for a wide range of landing-gear and impact parameters.

NACA TN 2756

NOISE FROM INTERMITTENT JET ENGINES AND STEADY-FLOW JET ENGINES WITH ROUGH BURNING. Leslie W. Lassiter. August 1952. 21p. diagrs. (NACA TN 2756)

Sound measurements were made on a pulse jet and a subsonic ram jet of the types used for helicopter rotor propulsion and on a turbojet with afterburner. The pulse jet was found to produce a discrete frequency spectrum in which the component corresponding to the engine firing frequency was generally predominant. An analysis of pulse jet noise, based on resonant-tube theory, is presented. The analysis allows a reasonable estimate of the noise level, if certain of the flow parameters of the engine are known. The small subsonic ram jet and the turbojet afterburner unit were found to produce discrete frequency spectrums somewhat similar to that of the pulse jet.

NACA TN 2757

EXPERIMENTAL STUDIES OF NOISE FROM SUBSONIC JETS IN STILL AIR. Leslie W. Lassiter and Harvey H. Hubbard. August 1952. 35p. diagrs., photos., tab. (NACA TN 2757)

Experimental studies have been made of the noise from a series of model subsonic jets ranging in diameter from 0.75 to 12.0 inches and the results are compared with data obtained for a turbojet engine. The effects of such parameters as jet size, exit gas

velocity, density, and turbulence level on the noise generated in the mixing region of a jet are evaluated. The velocity and turbulence level were found to have the greatest effect on the noise intensities and the frequency content was found to be a function of jet size and the observer's location. The noise generated by the turbojet engine was found to be closely related to that generated by simple model jets and an empirical relation is given to allow the extrapolation of available jet-noise data to other operating conditions.

NACA TN 2758

WEAR AND SLIDING FRICTION PROPERTIES OF NICKEL ALLOYS SUITED FOR CAGES OF HIGH-TEMPERATURE ROLLING-CONTACT BEARINGS. I - ALLOYS RETAINING MECHANICAL PROPERTIES TO 600° F. Robert L. Johnson, Max A. Swikert and Edmond E. Bisson. August 1952. 30p. diagrs., photos., 3 tabs. (NACA TN 2758)

Wear and sliding friction properties of a number of nickel alloys operating against hardened SAE 52100 steel were studied. These alloys include "L" nickel, wrought monel, cast monel, cast modified "H" monel, cast "S" monel, Invar, Ni-Resist 3, and Nichrome V. Some of the alloys studied may be useful as possible cage material for high-temperature, high-speed bearings for aircraft turbines or for bearings to operate in corrosive media. Desirable operating properties of all the materials could be associated with the development on the rider surface of a naturally formed film of nickel oxide. On the basis of wear and friction properties, Ni-Resist 3, modified "H" monel, and Invar were the best materials studied in this investigation although they did not perform as well as nodular iron. "L" nickel performed well with light loads but was not effective at higher loads when the surface film broke down.

NACA TN 2759

WEAR AND SLIDING FRICTION PROPERTIES OF NICKEL ALLOYS SUITED FOR CAGES OF HIGH-TEMPERATURE ROLLING-CONTACT BEARINGS. II - ALLOYS RETAINING MECHANICAL PROPERTIES ABOVE 600° F. Robert L. Johnson, Max A. Swikert and Edmond E. Bisson. August 1952. 29p. diagrs., photos., 3 tabs. (NACA TN 2759)

Wear and sliding friction properties of a number of nickel alloys operating against hardened SAE 52100 steel were studied. The alloys were cast beryllium nickel, heat-treated beryllium nickel, cast Inconel, Nimonic 80, Inconel X, Refractalloy 26, and Discaloy. Some of the alloys studied may be useful as material for cages of rolling-contact bearings that operate at high speeds with temperatures above 600° F in projected aircraft turbine engines or for bearings that operate in corrosive mediums. Desirable operating properties and the absence of extreme mass welding of all the materials studied could be associated with the development of the sliding surfaces of a naturally formed film of nickel oxide. On the basis of wear and friction properties, cast Inconel performed very well in these experiments and compares favorably with nodular iron. Nimonic 80 also showed promise as a possible cage material.

NACA TN 2760

DERIVATION OF STABILITY CRITERIONS FOR BOX BEAMS WITH LONGITUDINALLY STIFFENED COVERS CONNECTED BY POSTS. Paul Seide. August 1952. 21p. diagr. (NACA TN 2760)

An investigation has been made of the elastic stability of an idealized box beam with longitudinally stiffened covers connected by posts and subjected to end moments and axial loads. Stability criterions which give the axial stiffness of the posts required to achieve desired stress values in the box-beam covers are derived.

NACA TN 2761

INSTRUMENT-FLIGHT RESULTS OBTAINED WITH A COMBINED-SIGNAL FLIGHT INDICATOR MODIFIED FOR HELICOPTER USE. Almer D. Crim, John P. Reeder and James B. Whitten. August 1952. 13p. diagrs., photos. (NACA TN 2761)

A flight indicator which combines heading, altitude, bank-angle, and pitch-attitude information was modified for helicopter use and evaluated by means of instrument flights in a single-rotor helicopter. The modifications consisted of adding fuselage-rate-of-pitch signals to the instrument and increasing the ratio between heading and bank signals. The combined signal flight indicator enables the pilot to maintain more precise control of heading, altitude, and airspeed and required less concentration than with conventional instruments.

NACA TN 2764

ACCURACY OF APPROXIMATE METHODS FOR PREDICTING PRESSURES ON POINTED NONLIFTING BODIES OF REVOLUTION IN SUPERSONIC FLOW. Dorris M. Ehret. August 1952. 26p. diagrs. (NACA TN 2764)

The accuracy and range of applicability of the linearized theory, second-order theory, tangent-cone method, conical-shock-expansion theory, and Newtonian theory for predicting pressure distributions on pointed bodies of revolution at zero angle of attack are investigated. Various body shapes are included in the investigation and a wide range of supersonic Mach numbers and fineness ratios is included. It is found that, for most combinations of Mach number and fineness ratio, one of the approximate methods will give pressure drag within 10 percent.

NACA TN 2767

DYNAMICS OF MECHANICAL FEEDBACK-TYPE HYDRAULIC SERVOMOTORS UNDER INERTIA LOADS. Harold Gold, Edward W. Otto and Victor L. Ransom. August 1952. 63p. diagrs., photos. (NACA TN 2767)

An analysis of the dynamics of mechanical feedback-type hydraulic servomotors under inertia loads is developed and experimental verification is presented.

This analysis, which is developed in terms of two physical parameters, yields direct expressions for the following dynamic responses: (1) the transient response to a step input and the maximum cylinder pressure during the transient and (2) the variation of amplitude attenuation and phase shift with the frequency of a sinusoidally varying input. Close agreement was obtained between analytically determined responses and measured responses.

NACA TN 2768

SUPERSONIC FLOW WITH WHIRL AND VORTICITY IN AXISYMMETRIC CHANNELS. Ralph J. Eschborn. August 1952. 41p. diagrs. (NACA TN 2768)

Axially symmetric supersonic steady flow with vorticity and rotation about the axis is treated by the method of characteristics. Several cases are calculated for flow in annular channels.

NACA RM E52F05

ANALYSIS OF FULLY DEVELOPED TURBULENT HEAT TRANSFER AT LOW PECLET NUMBERS IN SMOOTH TUBES WITH APPLICATION TO LIQUID METALS. Robert G. Deissler. August 1952. 20p. diagrs. (NACA RM E52F05)

An analysis was made of heat transfer at low Peclet numbers for fluids flowing turbulently in smooth tubes. Previous analyses for flow of gases and liquid metals at low Peclet numbers gave higher heat-transfer coefficients than were indicated experimentally. When the mixing-length theory was modified in order to account for the heat transferred by conduction to a turbulent particle as it moves transversely, the predicted results were brought into agreement with the experimental results.

NACA RM E52F27

MINIMUM IGNITION ENERGIES OF SIX PURE HYDROCARBON FUELS OF THE C_2 AND C_6 SERIES. Allen J. Metzler. August 1952. 22p. diagrs., 3 tabs. (NACA RM E52F27)

Minimum spark-ignition energies at reduced pressures are reported for ethane, ethylene, acetylene, n-hexane, cyclohexane, and benzene; and the mean energy-pressure dependence is established to be $E \propto 1/P^{1.76}$. Minimum ignition energies E at 1 atmosphere predicted by this relation for these fuels correlate with the maximum fundamental flame velocity U_{max} and may be expressed approximately as $U_{max} \propto 1/E^{0.8}$. Such interdependence of the minimum ignition energy and maximum fundamental flame velocity permits a reasonable estimation of either from the other with an accuracy sufficient to discern large differences in various pure fuels.

BRITISH REPORTS

Royal Aircraft Establishment (Gt. Brit.)
THE FATIGUE SITUATION FOR CIVIL AIRCRAFT. P. B. Walker. May 1952. 4p. (RAE Structures 129)

This report is a reproduction for official use of a paper published in "The Aeroplane" for 25th April, 1952. The fatigue situation is reviewed briefly by eliminating all issues that appear to be secondary. There are found to be two main objectives: (a) to prevent fatigue accidents and (b) to obtain a long fatigue life. These are related to the broad technical picture which is also reviewed briefly. The conclusion reached is that the second objective is the more difficult to achieve.

Royal Aircraft Establishment (Gt. Brit.)
FLASH WELDING OF HIGH TENSILE STEEL TUBES - TEMPERATURE MEASUREMENTS. H. Brooks. December 1951. 28p. diagrs., photo., 6 tabs. (RAE Tech. Note Met. 153)

Measurements have been made to determine the effects of process variables on the temperatures produced in high tensile alloy steel tubes by the flashing phase of the welding cycle. The most important effects are those of flashing distance and speed. Initially, increases of flashing distance cause large temperature rises, but the effect diminishes as steady thermal conditions are approached. The steepness of the steady-state thermal gradients depends on the flashing speed, high speeds giving steep gradients. The effect is also apparent for nonsteady conditions if the gradients produced by different flashing speeds are compared on the basis of equal flashing distances. Average interface temperatures approximating to the steel melting point can only be attained at flashing speeds of about 1.0 in/min and higher. Machine secondary voltage was found to have a small inverted effect, higher temperatures being obtained with low voltages than with high. Within the range investigated, the effect of final die opening was negligible. Each particular set of flashing conditions produces very similar temperatures in tubes of different compositions and sizes.

N-16748*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) THE LOW SPEED PERFORMANCE OF A HELICOPTER. A. L. Oliver. May 15, 1952. 12p. diagrs. (AAEE Rept. A.A.E.E./Res/264)

The analysis and estimation of helicopter performance is dependent upon the accurate assessment of rotor induced velocity. An empirical curve relating the flow through the rotor to the flight speed is used for vertical flight and the momentum theory is sufficiently accurate for a tip speed ratio greater than

about 0.1, but no simple method has been generally available for the intermediary speed range. Sets of empirical curves covering this speed range and based on the analysis of low speed flight performance are given in this report. The charts give values of the rotor induced velocity varying smoothly from the verical flight state to the forward flight region in which the momentum theory becomes accurate. The charts are presented in forms suitable for determining steady flight performance and also for estimating rotor thrust during accelerated motion in, for example, take-off flight.

Royal Aircraft Establishment (Gt. Brit.)
THE DETERMINATION OF SKIN TEMPERATURES ATTAINED IN HIGH SPEED FLIGHT. F. V. Davies and R. J. Monaghan. February 1952. 65p. diagrs., 7 tabs. (RAE Aero 2454)

This report discusses the factors affecting skin temperatures attained by high-speed missiles and presents some methods of solution. These have been reduced to graphical or tabular form and are set out in order of complexity. Graphical or algebraic solutions may be quickly obtained if steady conditions are assumed, and for some flight cases these are reasonable approximations to corresponding transient solutions. If the temperature time variation is required, then longer numerical integration processes have to be performed. Account may be taken of external radiation and heat loss to the interior if their effects are considered significant. Although the emphasis of this report is on the calculation of average temperatures attained by thin skins, a method of calculating the temperature-space-time variation through three-dimensional bodies has been included assuming steady conditions at the surface. Numerical examples are included for each section of the report.

EXPERIMENTS ON DISTRIBUTED SUCTION THROUGH A ROUGH POROUS SURFACE. Cambridge University Aeronautical Laboratory. 1952. 7p. diagrs. (ARC CP 84)

Flight tests in which suction was applied through a slightly rough porous surface to maintain laminar flow in the boundary layer have shown that when the pressure on the surface was uniform there was an upper limit to the airspeed outside the layer above which no reasonable suction would prevent transition to turbulence. Comparison between these and similar tests on a smoother surface suggest that there will be, associated with every porous surface, two limiting speeds, one above which no reasonable suction will maintain laminar flow and one below which the surface can be regarded as aerodynamically smooth. Consideration is given to the way in which these speeds will vary with the kinematic viscosity of the air, in conditions which lead to dynamical similarity.

PRESSURE AND BOUNDARY LAYER MEASUREMENTS ON A 59° SWEPTBACK WING AT LOW SPEED AND COMPARISON WITH HIGH SPEED RESULTS ON A 45° SWEPT WING. PARTS I & II. Tunnel Staff of Aero Department & G. G. Brebner. 1952. 62p. diagrs., 19 tabs. (ARC CP 86)

The low speed pressure distributions has been measured over a range of incidence on a 59° swept wing of symmetrical section t/c 14 percent, aspect ratio 3.61, and taper ratio 4 to 1. These results have been compared, using the linear perturbation theory, with those on a 45° swept wing aspect ratio 5.87 at $M = 0.8$. There is fairly good agreement at zero incidence but lift distribution does not appear to be predicted so well. The results on the 59° wing show clearly the large effects of sweepback on both the pressure distribution at zero incidence and the lift distribution near the center section of the wing. Comparisons with theoretical estimates at zero incidence show good agreement.

FATIGUE TESTS ON TYPICAL TWO SPAR LIGHT ALLOY STRUCTURES (METEOR 4 TAILPLANES) UNDER REVERSED LOADING. K. D. Raithby. 1952. 24p. diagrs., photos., 3 tabs. (ARC CP 88)

Results are given for fatigue tests on six Meteor 4 tail planes vibrated in flexure under simple reversed loading, ranging from ±10 percent to ±30 percent of the static failing load. Corresponding endurances varied from about 5×10^6 to 0.06×10^6 cycles, for complete failure of a spar boom. In each test, the alternating load was kept constant, although progressive skin cracking caused a considerable change in alternating stress at the section where eventual failure of the spar boom occurred. The test results are discussed in relation to the establishment of endurance curves for a typical two-spar structure.

CORROSION AND FATIGUE TESTS ON MAGNESIUM ALLOYS TREATED BY A FRENCH GALVANIC PROCESS. H. G. Cole. February 1952. 13p. diagrs., 4 tabs. (RAE Tech.Note Met.156)

The Frasch galvanic process carried out in a solution of zinc dichromate containing a small amount of free chromic acid (Example I of B.P. Application 22986/46) gave good protection to three types of magnesium alloy and provided an excellent base for paint. Neither the Frasch galvanic process nor the RAE electrolytic chromate treatment caused any significant reduction of fatigue strength of magnesium alloy extruded bar to D.T.D.259. Chromate treatment in the RAE hot half hour bath caused an increase in fatigue strength.

ASYMPTOTIC EXPANSION OF THE WHITTAKER'S FUNCTION $W_{k,m}(z)$ FOR LARGE VALUES OF k, m, z. Chieh-Chien Chang, Boa-Teh Chu and Vivian O'Brien. September 1951. i, 54p. diagrs. (Johns Hopkins U.)

This problem of behavior, although mathematical in nature, arises in approximating to the third order the hodograph solution of transonic flow as shown in a previous report of the senior author. Debye's method of steepest descent has been applied, with Langer's method used as a check and comparison. Subsonic, sonic and supersonic flows have been investigated.

Some numerical examples of the asymptotic solutions have been caluclated for comparison with exact values. The subsonic and sonic cases seem to check reasonably well even for fairly small eigenvalues; the supersonic case does not check nearly so well for moderate n.

CURRENT NACA REPORTS

NACA Rept. 1028

EFFECT OF ASPECT RATIO ON THE AIR FORCES AND MOMENTS OF HARMONICALLY OSCILLATING THIN RECTANGULAR WINGS IN SUPERSONIC POTENTIAL FLOW. Charles E. Watkins. 1951. 17p. diagrs. (NACA Rept. 1028. Formerly NACA TN 2064)

The linearized velocity potential for a thin, flat, rectangular wing undergoing sinusoidal torsional oscillations simultaneously with sinusoidal vertical translations in a supersonic stream is derived in the form of an infinite series in terms of a frequency parameter. Simple closed expressions that include the reduced frequency to the third power are given for the velocity potential, components of total force and moment coefficients, and components of section force and moment coefficients. It is found that the components of force and moment coefficients for small-aspect-ratio wings may deviate considerably from those for an infinite-aspect-ratio wing. The method of solution can be utilized for other plan forms, that is plan forms for which steady-state solutions are known.

NACA Rept. 1053

INVESTIGATION OF TURBULENT FLOW IN A TWO-DIMENSIONAL CHANNEL. John Laufer, California Institute of Technology. 1951. 20p. diagrs., photos. (NACA Rept. 1053. Formerly TN 2123)

A detailed exploration of the turbulent flow characteristics in a two-dimensional channel is presented. The measurements were made at three Reynolds numbers, 12,300, 30,800, and 61,600, based on the half width of the channel and the maximum mean velocity. A channel of 5-inch width and 12:1 aspect ratio was used for the investigation.

NACA TN 2748

ON TRANSONIC FLOW PAST A WAVE-SHAPED WALL. Carl Kaplan. August 1952. 43p. diagrs. (NACA TN 2748)

The simplified nonlinear differential equation for transonic flow past a wavy wall is solved by the method of integration in series. A general procedure for the solution of the resulting recurrence formulas is shown and illustrated by a number of examples. A numerical test of convergence is applied to a key power series in k, the transonic similarity parameter, and leads to the conclusion that smooth symmetrical potential flow past the wavy wall is no longer possible when the critical value of the stream Mach number is exceeded.

NACA TN 2749

ANALYSIS OF FLOW IN A SUBSONIC MIXED-FLOW IMPELLER. Chung-Hua Wu, Curtis A. Brown and Eleanor L. Costilow. August 1952. 38p. diagrs. (NACA TN 2749)

A method recently developed for determining the steady flow of a nonviscous compressible fluid along a relative stream surface extending from hub to casing between two adjacent blades in a turbomachine is applied to investigate the through flow of air in an experimental mixed-flow impeller of high solidity. The shape of the stream surface is taken to be the same as that of the mean camber surface of the blade which consists of all radial elements. The principal equation governing the through flow is solved by the relaxation method with the use of fourth-degree differentiation formulas for unequally spaced grid points caused by the varying hub and casing wall radii.

A detailed analysis is made of both incompressible and compressible flow through the impeller, and contour plots of the stream function, velocity components, total enthalpy, static pressure, and Mach number are presented and discussed.

NACA TN 2762

AERODYNAMIC CHARACTERISTICS OF THREE DEEP-STEP PLANING-TAIL FLYING-BOAT HULLS AND A TRANSVERSE-STEP HULL WITH EXTENDED AFTERBODY. John M. Riebe and Rodger L. Naeseth. August 1952. diagrs., photos., 5 tabs. (NACA TN 2762. Formerly RM L8I27)

An investigation was made to determine the aerodynamic characteristics of three deep-step (92 percent of beam) planing-tail flying-boat hulls differing only in the amount of step fairing and of a transverse-step hull with extended afterbody. Minimum drag coefficients, which include the interference effects of the support wing, were 0.0066 for the transverse-step hull - about the same as for a conventional hull - and

0.0057 or 14 percent less for the hull with a deep unfaired step. The hulls with step fairing had up to 44 percent less drag. Longitudinal and lateral stability was about the same as for a conventional hull.

NACA TN 2763

GUST-RESPONSE ANALYSIS OF AN AIRPLANE INCLUDING WING BENDING FLEXIBILITY. John C. Houbolt and Eldon E. Kordes. August 1952. 48p. diagrs., 3 tabs. (NACA TN 2763)

An analysis is made of the gust response (including bending moment) of an airplane having the degrees of freedom of vertical motion and wing bending flexibility and basic parameters are established. A convenient numerical solution of the response equations, well-suited for trend studies, is developed and used in an example. A method is indicated for determining the gust causing a known response and a procedure is given for determining the response of an airplane directly from the known response of another airplane.

NACA TN 2766

SOME EFFECTS OF AMPLITUDE AND FREQUENCY ON THE AERODYNAMIC DAMPING OF A MODEL OSCILLATING CONTINUOUSLY IN YAW. Lewis R. Fisher and Walter D. Wolhart. September 1952. 24p. diagrs., photo. (NACA TN 2766)

A fuselage—vertical-tail combination was oscillated in yaw through a range of amplitudes from $1/2^{\circ}$ to 4° and a low range of the reduced-frequency parameter. The phase angles between the tail force and the displacement were measured and converted to values of the damping in yaw which are compared with the damping predicted by the unsteady-lift theories and with the experimental steady-state damping value. These tests were conducted at a Reynolds number of 442,000.

NACA TN 2769

EXPERIMENTAL AND THEORETICAL DETERMINATION OF THERMAL STRESSES IN A FLAT PLATE. Richard R. Heldenfels and William M. Roberts. August 1952. 35p. diagrs., photo. (NACA TN 2769)

Thermal stresses induced in a flat, rectangular, 75S-T6 aluminum-alloy plate by nonuniform heating are determined both experimentally and theoretically. The characteristics of commercially available bonded resistance wire strain gages are first investigated to determine their suitability for measuring stresses under simple conditions of stress and temperature. The gages are then used to measure thermal stresses in the flat plate in order to study their suitability under more complicated conditions. The experimental results are found to be in satisfactory agreement (within ±5 percent of maximum calculated stress) with an approximate theoretical solution of the problem.

NACA TN 2770

STUDY OF THE PRESSURE RISE ACROSS SHOCK WAVES REQUIRED TO SEPARATE LAMINAR AND TURBULENT BOUNDARY LAYERS. Coleman duP. Donaldson and Roy H. Lange. September 1952. 20p. diagrs., photos., tab. (NACA TN 2770. Formerly RM L52C21)

Results are presented of a dimensional study and an experimental investigation of the pressure rise across a shock wave which causes separation of the boundary layer on a flat plate. The experimental part of the investigation was conducted at a Mach number of 3.03 for a Reynolds number range of 2×10^6 to 19×10^6. The available experimental data are compared with the predictions of the present study, and the significance of the results obtained is discussed relative to certain practical design problems.

NACA TN 2771

THERMAL BUCKLING OF PLATES. Myron L. Gossard, Paul Seide, and William M. Roberts. August 1952. 39p. diagrs. (NACA TN 2771)

An approximate method, based on large-deflection plate theory, for calculating the deflections of flat or initially imperfect plates subject to thermal buckling is outlined. The method is used to determine the deflections of a simply supported panel subjected to a tentlike temperature distribution over the plate surface. Experimental results for a particular panel are in good agreement with the theoretical results considered in the test.

NACA TN 2772

DRIVING STANDING WAVES BY HEAT ADDITION. Perry L. Blackshear, Jr. August 1952. 46p. diagrs., photos. (NACA TN 2772)

Types of burner instability are enumerated and the role of standing waves in burners is discussed. The status of the problem of flame-driven standing waves is reviewed and a one-dimensional flow theory giving the mechanism whereby a flame drives or damps a standing wave is presented. In this theory, the reflection, transmission, and amplification of waves passing through a flame region were determined from the continuity and momentum equations. For the model considered, waves were found to pass through the flame front with their velocity amplitudes unaltered so long as the flame area remained unchanged. A change in flame area acted as a source of waves propagating simultaneously into the hot and cold gases on either side of the flame zone. The one dimensional theory seems an adequate explanation of the experimental observations.

NACA TN 2774

A METHOD FOR FINDING A LEAST-SQUARES POLYNOMIAL THAT PASSES THROUGH A SPECIFIED POINT WITH SPECIFIED DERIVATIVES. Neal Tetervin. September 1952. 11p. (NACA TN 2774)

A method is presented for finding a mth-degree polynomial that passes through a specified point with (m - j) specified derivatives ($1 \leq j \leq m$) and is a least-squares polynomial for other points which are spaced at unequal intervals of the independent variable.

NACA TN 2775

EFFECT OF LINEAR SPANWISE VARIATIONS OF TWIST AND CIRCULAR-ARC CAMBER ON LOW-SPEED STATIC STABILITY, ROLLING, AND YAWING CHARACTERISTICS OF A 45° SWEPTBACK WING OF ASPECT RATIO 4 AND TAPER RATIO 0.6. Byron M. Jaquet. August 1952. 27p. diagrs., 2 tabs. (NACA TN 2775)

An investigation was made in the Langley stability tunnel at low scale to determine low-speed effects of linear spanwise variations of twist and circular-arc camber on static-stability and rotary-stability (rolling and yawing) derivatives of a 45° sweptback wing of aspect ratio 4 and taper ratio 0.6.

NACA TN 2776

THE EFFECT OF A SIMULATED PROPELLER SLIPSTREAM ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT WING PANEL WITH AND WITHOUT NACELLES AT MACH NUMBERS FROM 0.30 TO 0.86. Gareth H. Jordan and Richard I. Cole. September 1952. 15p. diagrs., photo. (NACA TN 2776)

Results of an investigation are presented to show the effect of a simulated propeller slipstream on the lift, drag, and pitching-moment characteristics of an unswept wing panel with and without nacelles. The data were obtained in the Langley 24-inch high-speed tunnel through a range of Mach numbers from approximately 0.30 to 0.86 for angles of attack of 0° and 3°.

NACA TN 2777

THEORETICAL DISTRIBUTION OF SLIP ANGLES IN AN AGGREGATE OF FACE-CENTERED CUBIC CRYSTALS. John M. Hedgepeth. August 1952. 32p. diagrs. (NACA TN 2777)

An analysis of the relative frequency of occurrence of any given slip-line angle in a plastically deformed polycrystal composed of face-centered cubic crystals is presented for the case of simple tension. The results are compared with those obtained for a polycrystal composed of crystals which have but a single mode of slip and with experimental results. The comparisons show that the differences between the results obtained by the two theories become greater as the stress is increased. The comparison with experiment of the face-centered cubic theory is somewhat better than that of the single-slip-mode theory, but the errors are appreciable.

NACA TN 2778

STRESS AND STRAIN AT ONSET OF CRAZING OF POLYMETHYL METHACRYLATE AT VARIOUS TEMPERATURES. M. A. Sherman and B. M. Axilrod, National Bureau of Standards. September 1952. 21p. diagrs., photos., 3 tabs. (NACA TN 2778)

Stress and strain at the onset of crazing were determined for both general-purpose and heat-resistant grades of commercial cast polymethyl methacrylate. Tests were made at 23°, 50°, and 70° C on samples 0.15 inch thick. Other properties measured were tensile strength, total elongation, and modulus of elasticity. Results obtained indicate that a "critical-strain theory" for the threshold of crazing is not applicable to polymethyl methacrylate. Strain at the onset of crazing decreased with increase in temperature from 23° to 50° C whereas there was no consistent trend from 50° to 70° C. Stress at the onset of crazing was about 80 to 95 percent of the tensile strength at all three temperatures.

NACA RM E52F19

VISUALIZATION OF SECONDARY-FLOW PHENOMENA IN BLADE ROW. H. Z. Herzig, A. G. Hansen and G. R. Costello. August 1952. 20p. photos., diagrs. (NACA RM E52F19)

Flow-visualization methods were applied in a preliminary study of the streamline pattern of secondary flows in a blade row. The investigation demonstrated flow of the inlet-wall boundary layer in a blade passage into the corner between the blade suction surface and the wall to form a vortex. This vortex formation occurs well within the passage and is not a trailing-edge phenomenon. The magnitudes of the velocity gradients and angle deflections make the significance of quantitative measurements in this region questionable.

NACA RM E52G17

EFFECT OF FREE METHYL RADICALS ON SLOW OXIDATION OF PROPANE AND ETHANE. Glen E. McDonald and Rose L. Schalla. August 1952. 21p. diagrs., 4 tabs. (NACA RM E52G17)

A study of the effect of free methyl radicals on the slow oxidation of both ethane and propane was made by means of a photochemical decomposition reaction in a static system. The introduction of methyl radicals into a mixture of propane and oxygen or ethane and oxygen substantially lowered the initiation tem-

perature of the combustion of the hydrocarbon. Measurements were made of the amount of propane oxidized in the presence of free methyl radicals at temperatures ranging from 0° to 116° C and for two different concentrations of propane. Oxidation of ethane, which was induced by the free methyl radical, was investigated for only one concentration from 0° to 183° C. From a plot of the log percentage of propane oxidized against the reciprocal temperature ($^{\circ}$K), a zero activation energy was found for the reaction below 40° C. For ethane the activation energy was zero below 120° C. Above these two temperatures an increase in the activation energy was observed. A mechanism is proposed to account for the zero activation energy, but no attempt was made to interpret the higher temperature reactions.

NACA RM E52G24

INFLUENCE OF EXTERNAL VARIABLES ON SMOKING OF BENZENE FLAMES. Thomas P. Clark. August 1952. 17p. diagrs. (NACA RM E52G24)

Premixed benzene-air flames were burned with variations in initial gas temperature, fuel-flow rate, flame length, secondary-air-flow rate and burner-tube diameter. Fuel-air ratios were measured both at the initial appearance of incandescent carbon in the flame and at the point where smoke issued from the flame. Temperature alone affected the fuel-air ratio at which carbon first formed in the flame. The flame did not smoke under a fuel-air ratio of 164 percent of stoichiometric, regardless of the environment around the flame. Conditions which enhanced the diffusion of oxygen into the outer cone improved the smoke-burning characteristics of the flame.

NACA TM 1343

THE EXCITATION OF UNSTABLE PERTURBATIONS IN A LAMINAR FRICTION LAYER. (Die Anfachung instabiler Störungen in einer laminaren Reibungsschicht). J. Pretsch. September 1952. 63p. diagrs., 3 tabs. (NACA TM 1343. Trans. from Aerodynamische Versuchsanstalt Göttingen E. V., Institut für Forschungsflugbetrieb und Flugwesen; Jahrbuch der deutschen Luftfahrtforschung, August 1942, p. I 54-71).

With the aid of the method of small oscillations which was used successfully in the investigation of the stability of laminar velocity distributions in the presence of two-dimensional perturbations, the excitation of the unstable perturbations for the Hartree velocity distributions occurring in plane boundary-layer flow for decreasing and increasing pressure is calculated as a supplement to a former report. The results of this investigation are to make a contribution toward calculation of the transition point on cylindrical bodies.

NACA TM 1348

ON THE REPRESENTATION OF THE STABILITY REGION IN OSCILLATION PROBLEMS WITH THE AID OF THE HURWITZ DETERMINANTS. (Zur Darstellung des Stabilitätsgebietes bei Schwingungsaufgaben mit Hilfe der Hurwitz-Determinanten). E. Sponder. August 1952. 12p. diagrs. (NACA TM 1348. Trans from Schweizer Archiv für angewandte Wissenschaft und Technik, v. 16, no. 3, March 1950, p. 93-96).

This report concerns the use of the Hurwitz determinants in defining boundaries of regions where oscillatory phenomena are to be stable or unstable. A simplification is suggested as an aid in reducing the computations usually required, although it is emphasized that point checks in the various regions defined are required using the complete set of Hurwitz determinants or some other complete stability determination.

NACA TM 1352

TRANSITION CAUSED BY THE LAMINAR FLOW SEPARATION. (Sōryu-Hakuri ni tomonau Sen'i ni kansuru Kenkyū). T. Maekawa and S. Atsumi. September 1952. 14p. diagrs., 2 tabs. (NACA TM 1352. Trans from Society of Applied Mechanics of Japan, Journal, v. 1, no. 6, November 1948, p. 187-192)

An experimental investigation of the effects of the geometry of body surface, Reynolds number, stream turbulence, and a roughness element (wire) on the reattachment of separated laminar boundary-layer flow on a bent flat plate is presented and discussed. The flow mechanisms determining reattachment of the boundary layer are analyzed and discussed.

GROUND EFFECT ON DOWNWASH WITH SLIPSTREAM. P. R. Owen and H. Hogg. 1952. 12p. diagrs., 8 tabs. (ARC R & M 2449; ARC 7590. Formerly RAE Aero 1901)

It is shown in this report that given the downwash at the tail plane with slipstream, then the decrement in downwash at the same incidence and propeller thrust coefficient due to ground interference can be estimated by the formula of Piper and Davies (with certain slight modifications) with sufficient accuracy for most practical purposes.

N-16810*

TESTS ON A CONTROL WITH FIXED TRAILING-EDGE ANGLE, AND SURFACES OF VARIABLE CAMBER. A. S. Halliday, H. Deacon and W. C. Skelton. 1952. 15p. diagrs., 3 tabs. (ARC R & M 2495. Formerly ARC 10, 598; S & C 2116)

The report describes experiments to determine the effect of surface distortion on the hinge moments of a control and to investigate the importance of a rigid trailing edge in the prevention of large changes in hinge-moment coefficient. The results show that by designing the control so that the surface at the trailing edge, extending over one-eighth of the chord, is incapable of distortion, then the value of b_2 remains almost constant within the limits on any possible distortion forward of the fixed portion. It has also been found that b_1 is more constant. Changes in center line camber of the deformed portion of the control can still produce an effective change in b_2 when the camber varies with the control angle, although the amount of this change may be roughly halved. Present practice of treating trailing-edge angle as an important parameter in specifying control characteristics is well justified.

LIMITATIONS OF USE OF BUSEMANN'S SECOND-ORDER SUPERSONIC AEROFOIL THEORY. W. F. Hilton. 1952. 9p. diagrs. (ARC R & M 2524. Formerly ARC 9869; FM 971)

The author has found the Busemann theory very rapid in use for the determination of C_L, C_D, and C_m, and this report will enable the exact scope of its use to be determined. It has been tacitly assumed in the past that Busemann's second-order theory of airfoils at supersonic speeds was subject to the same limitations of wedge angle as the exact theory given by Lighthill and others, namely, the wedge angle at which the bow wave detaches. The range of angles for which Busemann's theory gives a pressure coefficient in error by less than 1 percent is shown to be smaller than the angle range for the shock wave to be attached. There is also a limit to the application of Busemann's method to angles of expansion as well as to angles of compression, unlike the exact theory, which can be extended to expansive angles of the order of one right angle without breaking down, in fact far beyond the useful range. The limits of angle given for the use of Busemann's theory are conservative, since they give the pressures to 1 percent, and the force coefficients will be more accurately determined since the errors tend to cancel out when integrating pressures to obtain forces.

NOTE ON THE EFFECT OF SIZE OF AIRCRAFT UPON THE DIFFICULTIES INVOLVED IN LANDING AN AIRCRAFT. D. Adamson. 1951. 13p. diagrs., tab. (ARC R & M 2567; ARC 10,903. Formerly RAE Aero 2202)

The effect of aircraft size upon the response of an aircraft during those maneuvers which are commonly employed in landing has been examined, and in this way an assessment has been made of the way in which the difficulties experienced by the pilot will go up as aircraft size increases. On the basis of the work summarized in this note, it is concluded that the problems associated with landing (from the pilot's point of view at any rate) are unlikely to be aggravated to such an extent, as the size of aircraft increases up to the limiting size considered in this report (300-ft span), as to make landing really difficult.

ON THE MOMENTUM EQUATION IN LAMINAR BOUNDARY-LAYER FLOW. A NEW METHOD OF UNIPARAMETRIC CALCULATION. B. Thwaites. 1952. 9p. (ARC R & M 2587. Formerly ARC 11,155; FM 1193; Perf. 397)

The general method of Pohlhausen, discussed in detail in reference 1, uses a uniparametric system of velocity distributions of the form $u/U = f(y/\delta) + \lambda g(y/\delta)$. Pohlhausen, by choosing simple forms for the functions f and g, then uses the momentum equation to find the distribution of δ with x and thence the distributions with x of the other boundary layer characteristics. Several awkwardnesses exist in his method, especially when it is applied to problems dealing with a normal velocity at the boundary. In this paper, a new method is described of combining velocity distributions in the form $y/\theta = F(u/U) + \lambda G(u/U)$, and it is shown that such a combination avoids several difficulties. This method of combination also allows a second parameter apart from λ, which might be found valuable in certain problems. The method has been briefly described before as part of an investigation into the effect of continuous suction on laminar boundary-layer flow under adverse pressure gradients. In that paper (R & M 2514), a numerical example of its use was given. In this paper, no example will be given because, as far as the author can see, the practical use of the method is superseded by the generalized method of reference 1; however, it possessed considerable analytical interest.

TABLES OF MULTHOPP AND OTHER FUNCTIONS FOR USE IN LIFTING-LINE AND LIFTING-PLANE THEORY. V. M. Falkner. WITH APPENDIX: CALCULATION OF THE CIRCULATION FROM THE DOWNWASH. E. J. Watson. 1952. 52p. diagrs., 8 tabs. (ARC R & M 2593. Formerly ARC 11,234; S & C 2187; Perf. 405)

The report gives the derivation and computed tables of two classes of functions suitable for the solution of problems of spanwise aerodynamic loading of wings either by lifting-line or lifting-plane theory. The functions are based on lifting-line theory, but, by a consideration of the connection between lifting-line and lifting-plane theory through the application of Munk's stagger theorem to the calculation of induced drag, it is deduced that the functions must be equally suitable for lifting-plane theory. The first range of functions, called Multhopp or M functions, is associated with discontinuities of induced downwash, while the second, called P functions because of the polygonal representation of induced downwash, is connected with discontinuities in rate of change of induced downwash. Examples are given of the combination of functions to produce given curves of induced downwash, and evidence of the close relation between the results for a continuous and stepped downwash curve suggests that the functions tabulated will be sufficient to cover almost any problem in wing loading.

CALCULATED AERODYNAMIC CHARACTERISTICS OF TWO INFINITE WINGS WITH CONSTANT CHORD. V. M. Falkner. 1952. 10p. diagrs., 8 tabs. (ARC R & M 2594. Formerly ARC 10,628; S & C 2123; Perf. 325)

The report gives solutions obtained by the vortex lattice method for the aerodynamic loading of two infinite wings of constant chord with sweepback of 45°, one with a V-joint at the center, the other rounded off with arcs of radius four times the chord. The true mathematical solution for these problems is exceedingly difficult to find, and the accuracy has been verified by considering the convergence of solutions of varying complexity. The V-wing shows a reduction in circulation near the joint with accompanying backward movement of the local center of pressure, while the rounded wing has increased circulation without appreciable variation of the center of pressure from the 0.25-chord position. The results will be used to modify loading functions used in vortex lattice theory in order to improve solutions for wings of small aspect ratio, particularly when the leading or trailing edges meet at an included angle which differs considerably from 180°.

APPLICATION OF THE LINEAR PERTURBATION THEORY TO COMPRESSIBLE FLOW ABOUT BODIES OF REVOLUTION. A. D. Young and S. Kirkby. 1952. 8p. diagrs. (ARC R & M 2624; ARC 11,033; FM 1177. Formerly College of Aeronautics, Cranfield Rept. 11)

The linearized theory is developed in some detail in order to clarify the difference between two dimensional flow and flow past slender three-dimensional bodies. In agreement with other authors, it is concluded that the perturbation velocity on a slender body in compressible flow is $1/\beta^2$ times the perturbation velocity in incompressible flow on a thinner body at reduced incidence obtained by reducing the lateral dimensions of the original body in the ratio β:1. This result is applied to a representative family of streamline bodies of revolution at zero incidence. It is found that, without an undue loss of accuracy, the results of the claculations can be presented in a relatively simple form in a diagram showing the variation of velocity with Mach number for a range of values of velocity on the surface of a streamline body in incompressible flow. This variation is always less than that predicted by the Glauert law but approaches it with increase in the basic incompressible flow velocity, being very close to it for basic incompressible velocity ratios, u/U_0, of 1.10 and higher. It is shown that the blockage factor for a body of revolution in a wind tunnel is increased in compressible flow in the ratio $1\beta^3$ and not $1/\beta^4$ as quoted in R & M 1909.

MODEL TESTS IN THE 24-FT WIND TUNNEL TO DETERMINE THE OPTIMUM ANGLE FOR RELEASE OF A COCKPIT HOOD. R. Fail. 1952. 3p. diagrs. (ARC R & M 2644; ARC 11,494. Formerly RAE Tech. Note Aero 1947)

For some time now, it has been recommended that mechanical assistance be incorporated in jettisonable cockpit hood designs. Some firms have preferred designs in which the hood is constrained to rotate through a definite angle before the final release. A short series of tests has, therefore, been made in the 24-ft wind tunnel to determine the optimum angle for release. This was found to be about 10°, which is considerably less than has been suggested in the past.

WIND-TUNNEL TESTS ON A THICK SUCTION AEROFOIL WITH A SINGLE SLOT. M. B. Glauert, W. S. Walker, W. G. Raymer and N. Gregory. 1952.

14p. diagrs., tab. (ARC R & M 2646; ARC 11,797. Formerly ARC 10,854; Perf. 348; FM 1150)

This report describes the two-dimensional wind-tunnel tests carried out in the National Physical Laboratory 13- by 9-ft wind tunnel on a 31.5-percent-thick suction airfoil, GLAS II, which has a single slot on the upper surface at 69 percent chord. Both suction and blowing were used to prevent separation. Lift, drag, pitching moment, and the flow through the slot were measured. Tests without suction were made at Reynolds numbers of 0.96 and 2.88 million. The results at the two Reynolds numbers were markedly different, and at the higher speed widely varying values of the drag coefficient were recorded in the same conditions, there apparently being several possible régimes of flow. With suction, the pump power available only enabled tests to be made at the lower Reynolds number, and with the boundary layer on the upper surface laminar to the slot. At low incidences, suction quantities agreeing well with theoretical estimates sufficed to maintain unseparated flow, but at higher incidences the flow tended to break down. Three or four times as much suction was required at all incidences to make the separated flow readhere. With blowing, still larger quantities were necessary, but the spanwise distribution of the flow from the slot was unsatisfactory. Two different slot shapes were tested on the model, one with a sharp beak to the front lip, the other with a rounded entry. Intermittent separation of the flow occurred in each case. The phenomena may be of a fundamental character and associated with the profile shape rather than with the shape of the slot entry.

APPARATUS FOR OBTAINING A WIDE RANGE OF HUMIDITY AND TEMPERATURE CONDITIONS IN A STREAM OF AIR. A. T. Josling. May 1952. 4p. diagrs., photos. (AID Rept. APP. 3)

A new type of apparatus for obtaining any desired humidity in a stream of air is described. It is based on the principle of saturating air at a suitable temperature and then heating it to the working temperature. Saturation is obtained by means of a special splashing device without atomization. Since the saturation temperature to give the desired humidity at the working temperature, which may be anywhere within its wide range, is known from hygrometric tables, an actual determination of the humidity achieved is rendered unnecessary. The apparatus is suitable for blushing tests on paints and dopes, corrosion tests on platings, protective coatings, oils and greases.

TRIALS OF TIMBER FOR PLYWOOD MANUFACTURE. PROGRESS REPORT SIXTEEN. June 1952. 9p. 5 tabs. (Forest Products Research Lab.)

Tests were made on three British Guiana species of wood. They were crabwood (carapa guianensis), kurokai (protium decandrum), and wamara (swarzia leiocalycina). It was found that the crabwood would be unsuitable for British mills but it may be of some use for conversion in the country of origin if freshly felled logs are less prone to splitting and shaking. Kurokai would also be unsuited to British mills but would be of use in the country or origin. Wamara is considered unsuitable because of its weight and processing difficulties.

FORMS OF WING FLUTTER IN TWO-DIMENSIONAL COMPRESSIBLE POTENTIAL FLOW. (Flugelschwingungsformen in ebener kompressibler Potentialströmung). Nikolaus Rott. July 1952. 44p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 1, 1950, p. 380-410)

On the basis of energy considerations, a survey is given of the possible forms of oscillations for flutter with two degrees of freedom in a plane compressible potential flow. It is found that the possible forms do not much depend on Mach number in the whole range from 0 to α, with some exceptions in the neighborhood of M = 1, where forms with only one degree of freedom (torsion) may occur. Conclusions are drawn for methods of preventing flutter. Limits of the reduced frequency are given for the possibility of flutter in two and one degree of freedom. Special care was given for the case of M = 1.

CALCULATION OF THE LATERAL CONTROL OF SWEPT AND UNSWEPT FLEXIBLE WINGS OF ARBITRARY STIFFNESS. Franklin W. Diederich. 1951. ii, 19p. diagrs., 6 tabs. (NACA Rept. 1024. Formerly RM L8H24a)

A method similar to that of NACA Rept. 1000 is presented for calculating the effectiveness and the reversal speed of lateral-control devices on swept and unswept wings of arbitrary stiffness. Provision is made for using either stiffness curves and root-rotation constants or structural influence coefficients in the analysis. Computing forms and an illustrative example are included to facilitate calculations by means of the method. The effectiveness of conventional aileron configurations and the margin against aileron reversal are shown to be relatively low for swept wings at all speeds and for all wing plan forms at supersonic speeds.

National Advisory Committee for Aeronautics.
A GENERAL INTEGRAL FORM OF THE BOUNDARY-LAYER EQUATION FOR INCOMPRESSIBLE FLOW WITH AN APPLICATION TO THE CALCULATION OF THE SEPARATION POINT OF TURBULENT BOUNDARY LAYERS. Neal Tetervin and Chia Chiao Lin. 1951. 19p. diagrs. (NACA Rept. 1046. Formerly TN 2158)

A general integral form of the boundary-layer equation, valid for either laminar or turbulent incompressible boundary-layer flow, is derived. By using the experimental finding that all velocity profiles of the turbulent boundary layer form essentially a single-parameter family, the general equation is changed to an equation for the space rate of change of the velocity-profile shape parameter. The lack of precise knowledge concerning the surface shear and the distribution of the shearing stress across turbulent boundary layers prevented the attainment of a reliable method for calculating the behavior of turbulent boundary layers.

National Advisory Committee for Aeronautics.
THEORETICAL ANTISYMMETRIC SPAN LOADING FOR WINGS OF ARBITRARY PLAN FORM AT SUBSONIC SPEEDS. John DeYoung. 1951. 36p. diagrs., 9 tabs. (NACA Rept. 1056. Formerly TN 2140)

A simplified lifting-surface theory that includes effects of compressibility and spanwise variation of section lift-curve slope is used to provide charts with which antisymmetric loading due to arbitrary antisymmetric angle of attack can be found for wings having symmetric plan forms with a constant spanwise sweep angle of the quarter-chord line. Aerodynamic characteristics due to rolling, deflected ailerons, and sideslip of wings with dihedral are considered. Solutions are presented for straight-tapered wings for a range of swept plan forms.

NACA Rept. 1066
National Advisory Committee for Aeronautics.
ANALYSIS OF TEMPERATURE DISTRIBUTION IN LIQUID-COOLED TURBINE BLADES. John N. B. Livingood and W. Byron Brown. 1952. ii, 21p. diagrs. (NACA Rept. 1066. Formerly TN 2321)

Analytical methods are presented for computing temperature distributions in liquid-cooled turbine blades or in simplified shapes used to approximate sections of liquid-cooled turbine blades. Nondimensional charts are presented for use in the simplification of some of the calculations. Illustrative examples are also included to demonstrate the use of the various equations and nondimensional charts and to show trends of the various temperature distributions. One-dimensional spanwise temperature distributions gave satisfactory results near the coolant passages. One-dimensional chordwise distribution gave a good first approximation to the actual solution in cases when rim cooling was insignificant.

NACA TN 2765

A FLIGHT INVESTIGATION OF THE EFFECT OF SHAPE AND THICKNESS OF THE BOUNDARY LAYER ON THE PRESSURE DISTRIBUTION IN THE PRESENCE OF SHOCK. Eziaslav N. Harrin. September 1952. 13p. diagrs., photos. (NACA TN 2765)

An investigation was made in flight at free-stream Mach numbers up to about 0.77 to determine the effect of a laminar boundary layer and thin and thick turbulent boundary layers on the chordwise pressure distribution over an airfoil in the presence of shock at full-scale Reynolds numbers. Boundary-layer and pressure-distribution measurements were made on a short-span airfoil built around a wing of a fighter airplane. Boundary-layer Reynolds numbers (based on momentum thickness and flow parameters at the outer edge of the boundary layer) were about 3,000 for the laminar boundary layer and 10,000 for the thickest turbulent boundary layer with local Mach numbers ranging up to 1.3 and chord Reynolds numbers up to about 21×10^6.

NACA TN 2773

AN APPROXIMATE METHOD FOR DETERMINING THE DISPLACEMENT EFFECTS AND VISCOUS DRAG OF LAMINAR BOUNDARY LAYERS IN TWO-DIMENSIONAL HYPERSONIC FLOW. Mitchel H. Bertram. September 1952. 41p. diagrs., photos., tab. (NACA TN 2773)

A simplified approximate theory is presented by means of which the laminar boundary layer over an insulated two-dimensional surface may be calculated, a linear velocity profile being assumed, and an estimate made of its effect in changing the pressure distribution over the profile upon which the boundary layer is formed. Skin friction is also determined. Comparisons of results from this theory are made with experimental results at a Mach number of 6.86 and a Reynolds number of 980,000.

NACA TN 2780

FLIGHT INVESTIGATION OF TRANSIENT WING RESPONSE ON A FOUR-ENGINE BOMBER AIRPLANE IN ROUGH AIR WITH RESPECT TO CENTER-OF-GRAVITY ACCELERATIONS. Harry C. Mickleboro, Richard B. Fahrer and C. C. Shufflebarger. September 1952. 25p. diagrs., 3 tabs. (NACA TN 2780)

The results of a flight investigation on a four-engine bomber airplane to determine the transient-response effects of wing flexibility in gusts showed that the measured acceleration increments at the center of gravity were approximately 28 percent higher than the true airplane acceleration increments. This relationship appeared to be only slightly affected by the variations in speed and weight covered by the test conditions.

NACA TN 2783

USE OF A CONSOLIDATED POROUS MEDIUM FOR MEASUREMENT OF FLOW RATE AND VISCOSITY OF GASES AT ELEVATED PRESSURES AND TEMPERATURES. Martin B. Biles and J. A. Putnam, University of California. September 1952. 51p. diagrs., photos., 7 tabs. (NACA TN 2783)

Use of a consolidated porous medium as a gas-metering device and for determination of gas viscosity has been investigated over a moderate range of temperature and pressure. With normal laboratory techniques it appears possible to calibrate large porous Alundum filtering thimbles to meter gas with a probable error of 0.1 to 0.2 percent. The geometry of such elements permits an appreciable range of gas flow rate to be metered with small, accurately controlled, pressure drops. The advantages of such a device warrant its use as a laboratory instrument. Results of the flow tests have been employed in the determination of the viscosity of air up to approximately 900 pounds per square inch absolute at the two test temperatures of 75° and 517° F. These data appear to check sufficiently well with other published viscosity data to justify the use of this method as a recommended procedure.

NACA TN 2784

METHOD FOR CALCULATION OF COMPRESSIBLE LAMINAR BOUNDARY-LAYER CHARACTERISTICS IN AXIAL PRESSURE GRADIENT WITH ZERO HEAT TRANSFER. Morris Morduchow and Joseph H. Clarke, Polytechnic Institute of Brooklyn. September 1952. 43p. diagrs., 4 tabs. (NACA TN 2784)

The Kármán-Pohlhausen method is extended primarily to sixth-degree velocity profiles for determining the characteristics of the compressible laminar boundary layer over an adiabatic wall in the presence of an axial pressure gradient. It is assumed that the Prandtl number is unity and that the coefficient of viscosity varies linearly with the temperature. A general approximate solution which permits a rapid determination of the boundary-layer characteristics for any given free-stream Mach number and given velocity distribution at the outer edge of the boundary layer is obtained. A simple method based on the use of a seventh-degree velocity profile is derived for the special purpose of calculating the location of the separation point in an adverse pressure gradient. It is shown that for the special case of flow near a forward stagnation point the Kármán-Pohlhausen method with the usual forth-degree profiles leads to results of adequate accuracy, even for the critical Reynolds number.

NACA TN 2785

INTRODUCTION TO ELECTRICAL-CIRCUIT ANALOGIES FOR BEAM ANALYSIS. Stanley U. Benscoter and Richard H. MacNeal, California Institute of Technology. September 1952. 48p. diagrs., 5 tabs. (NACA TN 2785)

An application is described of the well-known analogy between electrical and mechanical systems to the calculation of stresses and deflections of beams. The object of the present paper is to give an explanation of the analogies in an elementary manner which will enable a structural engineer to understand the process of designing the electrical circuits. The analogies which are discussed are those that are now being used in the Cal-Tech analog computer. Analogies are given for beams in bending and torsion with static loads and in vibrational motion.

NACA TN 2786

EQUIVALENT PLATE THEORY FOR A STRAIGHT MULTICELL WING. Stanley U. Benscoter and Richard H. MacNeal, California Institute of Technology. September 1952. 32p. diagrs. (NACA TN 2786)

A structural theory is developed for the analysis of thin multicell wings with straight spars and perpendicular ribs. The analysis is intended to be suitable for supersonic wings of low aspect ratio. Deflections due to shearing strains are taken into account. The theory is expressed entirely in terms of first-order difference equations in order that analogous electrical circuits can be readily designed and solutions obtained on the Cal-Tech analog computer.

NACA TN 2787

AIRFOIL PROFILES FOR MINIMUM PRESSURE DRAG AT SUPERSONIC VELOCITIES - APPLICATION OF SHOCK-EXPANSION THEORY, INCLUDING CONSIDERATION OF HYPERSONIC RANGE. Dean R. Chapman. September 1952. 44p. diagrs. (NACA TN 2787)

A theoretical investigation employing shock expansion theory is made of the airfoil profile having minimum pressure drag at zero lift for various given auxiliary conditions. Curves are presented to facilitate the application of the theory, and typical optimum profiles are illustrated. A comparison of results obtained by the simpler linearized-theory method of a previous report indicates that the simpler method can be used with engineering accuracy to determine the shape, though not the drag, of the optimum profile at Mach numbers up to infinity. It is shown that considerable deviation from the optimum shape can be made without a large increase in drag except on thin airfoils at moderate supersonic Mach numbers.

NACA TN 2788

EFFECTS OF SOLVENTS IN IMPROVING BOUNDARY LUBRICATION OF STEEL BY SILICONES. S. F. Murray and Robert L. Johnson. September 1952. 23p. diagrs., 2 tabs. (NACA TN 2788)

Because of the known synthetic fluids, silicones best satisfy the viscometric requirements for lubricants for turbine engines, a study was conducted to establish the effect of solvents on boundary lubrication by silicones. Boundary-lubrication data were obtained which are considered substantiating evidence for a hypothesis that, in solutions of solvents blended with silicones, the silicones form a closely packed and oriented adsorbed film on ferrous surfaces. The solutions reduced friction and prevented surface failure even when the solvent as well as the silicone was an extremely poor lubricant. These data indicate that satisfactory lubrication is the result of a solvation effect rather than a lubrication additive effect of the solvent because 30 to 50 percent of solvent was necessary for good results. The best results were obtained with solvents having dipole moments. Solutions of diesters in silicones may be practical lubricants.

NACA TN 2789

SOME DYNAMIC EFFECTS OF FUEL MOTION IN SIMPLIFIED MODEL TIP TANKS ON SUDDENLY EXCITED BENDING OSCILLATIONS. Kenneth F. Merten and Bertrand H. Stephenson. September 1952. 35p. diagrs., photos., 2 tabs. (NACA TN 2789)

An exploratory investigation of the dynamic effects of fuel sloshing in tip tanks on wing bending motion was conducted with two simplified model beam-tank systems. Envelope curves to beam-displacement time histories obtained after release from a deflected position are compared and show the effects of variation in tank fullness, fluid density, fluid viscosity, and tank shape. Some variations of fluid weight effective from cycle to cycle are also presented. The results of these tests indicate that after several cycles substantial damping may be obtained from fuel sloshing in a tip tank and that the effective mass of the fuel may vary considerable under certain conditions of tank oscillation. The viscosity of the fluid did not affect the damping or inertia characteristics obtained but, for a given beam-tank system, the density of fluid and tank fullness were important parameters.

NACA TN 2791

CORRELATION OF TENSILE STRENGTH, TENSILE DUCTILITY, AND NOTCH TENSILE STRENGTH WITH THE STRENGTH OF ROTATING DISKS OF SEVERAL DESIGNS IN THE RANGE OF LOW AND INTERMEDIATE DUCTILITY. Arthur G. Holms and Andrew J. Repko. September 1952. 30p. diagrs., 3 tabs. (NACA TN 2791)

Burst tests were conducted on several designs of sound disks and disks with defects and results were compared with tensile strength, tensile ductility, and notch tensile strength. For the brittle materials, the disk strength did not correlate with tensile strength. For the brittle materials and for ductile materials for which notch strength data were available, the disk strength was found to correlate better with the combination of tensile strength and notch strength ratio than with the combination of tensile strength and elongation. For disks with defects, the notch tensile strength was superior to the conventional tensile strength.

NACA TN 2793

A METHOD FOR THE DETERMINATION OF THE TIME LAG IN PRESSURE MEASURING SYSTEMS INCORPORATING CAPILLARIES. Archibald R. Sinclair and A. Warner Robins. September 1952. 35p. diagrs., tab. (NACA TN 2793)

A method is presented for the determination of the time lag in pressure measuring systems incorporating capillaries; this method is a convenient and systematic means of selecting, designing, or redesigning a pressure measuring system to meet the time requirements of a particular installation. Experimental data are shown and a step-by-step sample application is presented.

NACA TN 2795

EFFECTS OF WING SWEEP ON THE UPWASH AT THE PROPELLER PLANES OF MULTIENGINE AIRPLANES. Vernon L. Rogallo. September 1952. 46p. diagrs. (NACA TN 2795)

An analysis is presented to give a qualitative picture of the effects of wing sweep on the upwash at the propeller planes of multiengine airplanes. In order to provide a basis for judging effects of sweep, comparisons are made of the upwash and upflow angles at the propeller planes of two hypothetical airplanes of the high-speed long-range type, one having an unswept wing and the other a sweptback wing. The effects of compressibility are considered. Charts are provided to enable the prediction of upwash in the chord-plane region ahead of wings of various plan forms.

NACA RM E52B12

IMPINGEMENT OF WATER DROPLETS ON AN NACA 65_1-212 AIRFOIL AT AN ANGLE OF ATTACK OF 4°. Rinaldo J. Brun, John S. Serafini and George J. Moshos. September 1952. 47p. diagrs., tab. (NACA RM E52B12)

The trajectories of droplets in the air flowing past an NACA 65_1-212 airfoil at an angle of attack of 4° were determined. The collection efficiency, the area of droplet impingement, and the rate of droplet impingement were calculated from the trajectories. The results are applicable under the following conditions: chord lengths from 2 to 20 feet, altitudes from 1000 to 35,000 feet, airplane speeds from 150 miles per hour to the critical flight Mach number, and droplet diameters from 5 to 100 microns.

NACA RM E52H15

PRESSURE LIMITS OF FLAME PROPAGATION OF PURE HYDROCARBON-AIR MIXTURES AT REDUCED PRESSURES. Adolph E. Spakowski. September 1952. 35p. diagrs., 2 tabs. (NACA RM E52H15)

An investigation was made of the pressure concentration limits of flame propagation in glass tubes for 18 high-boiling hydrocarbons mixed with air. The concentration limits were correlated with molecular weight. Relations were also derived between the flammability range and the molecular weight and between the rich and lean limits.

NACA RM L52G18

INVESTIGATION OF THE EFFECTS OF VARIATIONS IN THE REYNOLDS NUMBER BETWEEN 0.4×10^6 AND 3.0×10^6 ON THE LOW-SPEED AERODYNAMIC CHARACTERISTICS OF THREE LOW-ASPECT-RATIO SYMMETRICAL WINGS WITH RECTANGULAR PLAN FORMS. George W. Jones, Jr. September 1952. 13p. diagrs. (NACA RM L52G18)

The effects of Reynolds number on the aerodynamic characteristics of three symmetrical wings of aspect ratio 1, 2, and 3 each having a rectangular plan form and an NACA 0012 airfoil section is given for a range of seven Reynolds numbers between 0.4×10^6 and 3.0×10^6. The data show the effects of Reynolds number on the lift, the lift-curve slope, maximum lift coefficient, and the pitching moment about the quarter-chord point.

NACA TM 1337

ANALYTICAL STUDY OF SHIMMY OF AIRPLANE WHEELS. (Étude Théorique du Shimmy des Roues d'Avion). Christian Bourcier de Carbon. September 1952. 126p. diagrs., photos. (NACA TM 1337. Trans. from Office National d'Etudes et de Recherches Aéronautiques, Pub. 7, 1948).

The problem of shimmy of a castering wheel, such as the nose wheel of a tricycle gear airplane, is treated analytically. The flexibility of the tire is considered to be the primary cause of shimmy. The rather simple theory developed agrees rather well with previous experimental results. The author suggests that shimmy may be eliminated through a suitable choice of landing gear dimensions in lieu of a damper.

Aeronautical Research Council (Gt. Brit.)
TWO-DIMENSIONAL WIND TUNNEL INTERFERENCE. L. G. Whitehead. June 17, 1950. 24p. diagrs. (ARC 13,198; FM 1451)

The present paper describes a contribution to the theory of two-dimensional wind-tunnel interference on bodies set at zero incidence in the center of the flow. The work is limited to incompressible flow. The irrotational flow has been found between parallel walls and also in a free jet past two cylindrical sections. The first of these is a circular cylinder and the second is a slender profile with a uniform pressure drop over the greater part of the boundary. No account is taken of the wake which exists behind a body in a real fluid so that the tunnel interference represented in the present paper is that usually referred to as solid blockage and the effects of wake blockage are not considered. The free streamline method is employed for the calculation of the flow of a jet past both bodies so that the outward displacement of the streamline is correctly represented and the approximations associated with the application of the method of images to these problems are avoided. The results are not limited therefore to examples in which the profile dimensions are small compared with the width of the jet. The free streamline method has an additional advantage as the solutions can readily be adapted to deal with problems in which the outer boundaries of the flow consist partly of parallel walls and partly of free streamlines.

THE LAMINAR AXI-SYMMETRIC JET: EXACT SOLUTION. H. B. Squire. July 22, 1950. 7p. diagrs. (ARC 13,267; FM 1462)

A solution of the flow in a laminar axisymmetric jet was given by Schlichting in 1933, making use of the approximations of boundary-layer theory. The corresponding exact solution of the Navier-Stokes equations is derived in the present report. It is also shown that this solution can be interpreted as the flow resulting from a force applied at a point in a viscous fluid which is at rest at infinity.

National Gas Turbine Establishment (Gt. Brit.)
SOME EXPERIMENTS ON BREAKDOWN POTENTIAL IN HOT PRODUCTS OF COMBUSTION. N. A. Dimmock. May 1952. 14p. diagrs., tab. (NGTE Memo. M. 153)

The experiments described in this memorandum show that no general lowering of the breakdown potential is caused by the ionization present in the exhaust gases from a combustion chamber, although a slight drop in its value is noticeable very close to the chamber exit. The fuels used were aviation kerosene, gas oil (Marine reference B. 310) and gas oil with n-Butyl disulphide. The ceramic insulator used in the experiments was found to become semiconducting at elevated temperatures and this trouble would have to be overcome in designing an electrode for a hot gas electrostatic-cleaner.

MEASUREMENT OF THE MOISTURE CONTENT OF HIGH PRESSURE OXYGEN FOR USE IN AIRCRAFT. I. A LOW PRESSURE HYGROMETER. M. E. Bedwell and W. G. Glendinning. March 1952. 9p. diagrs., 3 tabs. (RAE Tech. Note Chem. 1154)

A hygrometer has been devised which will give precise measurement of the moisture content of oxygen issuing from a cylinder. Test runs on samples from transport cylinders indicate that in every case the oxygen contained considerably less than the maximum amount of moisture allowed by specification. No anomalous changes of moisture content with decreasing pressure were observed in the cylinders selected.

FREQUENCY REGULATOR FOR A MOTOR-ALTERNATOR. C. S. Hudson. January 1952. 17p. diagrs., photo. (RAE Tech. Note EL. 30)

The design of a frequency regular for a 2 kw 333 cps motor alternator is described and details given of the experimental measurements made. A two stage magnetic amplifier is used having a current gain of about 3000 and a power amplification of about 10^8. The design is intended to give regulation to within 0.1 percent; from approximate measurements made it is considered to be better than 0.3 percent. No attempt has been made to examine the stability of the frequency reference circuit and further work on this needs to be done.

SOME MEASUREMENTS OF TAKEOVER TIME LAGS IN THE STRIKING OF COLD-CATHODE TRIODES. J. C. Le Grice. March 1952. 16p. diagrs., photos. (RAE Tech. Note EL. 32)

The design of time-delay circuits using cold-cathode triodes necessitated a knowledge of the magnitude of the takeover time by which striking of the anode circuit lags behind striking of the trigger circuit. A method of applying the trigger and anode voltage wave forms to the deflection plates of a C. R. O. is described which enabled the takeover time to be measured between the attainment of currents of 10^{-3} amps in the trigger and anode circuits respectively. Some measurements on miniature triodes with potassium cathodes gave takeover times of less than 50 μs for anode voltages between 100 and 200 volts. The takeover times were repeatable to better than 5 percent.

TOWING TANK TESTS TO DETERMINE THE WATER DRAG AND PITCHING MOMENTS ON THE FINAL HULL FORM OF A LARGE FLYING BOAT SEAPLANE (PRINCESS, SPEC. 10/46). T. B. Owen and A. G. Kurn. April 1952. 33p. diagrs., photo., 5 tabs. (RAE Tech. Note Aero 2159)

The water drag, trim and hull wetted areas of the Princess flying boat hull model (final form) have been measured for all anticipated take-off weights and attitudes. The drag characteristics compare favorably with those obtained on other boat seaplanes. The measurements were made using new techniques for: model surface finish, drag measurements, and representation of the effect of air flow past the model. A method is given for correcting the model drag data to full scale to allow for the difference is Reynolds number.

CURRENT NACA REPORTS

NACA Rept. 1026

NACA INVESTIGATION OF FUEL PERFORMANCE IN PISTON-TYPE ENGINES. Henry C. Barnett. 1951. vi, 102p. diagrs., photos., 32 tabs. (NACA Rept. 1026)

A compilation of many of the pertinent research data acquired by the NACA on fuel performance in piston engines. The following specific subjects are discussed: High-speed photographic studies of knocking combustion, by C. David Miller; correlations of knock-limited performance data; antiknock performance scales; preignition; hydrocarbons and ethers as antiknock blending agents; aromatic amines as fuel additives; tetraethyl lead as a fuel additive; antiknock blending characteristics of fuels; fuel volatility; and internal cooling.

NACA Rept. 1054

INTEGRALS AND INTEGRAL EQUATIONS IN LINEARIZED WING THEORY. Harvard Lomax, Max A. Heaslet and Franklyn B. Fuller. 1951. ii, 34p. diagrs. (NACA Rept. 1054. Formerly TN 2252)

The formulas of subsonic and supersonic wing theory for source, doublet, and vortex distributions are reviewed, and a systematic presentation is provided which relates these distributions to the pressure and to the vertical induced velocity in the plane of the wing. It is shown that care must be used in treating the singularities involved in the analysis and that the order of integration is not always reversible. Concepts suggested by the irreversibility of order of integration are shown to be useful in the inversion of singular integral equations when operational techniques are used. A number of examples are given to illustrate the methods presented, attention being directed to supersonic flight speeds.

NACA Rept. 1065

CORRELATION OF PHYSICAL PROPERTIES WITH MOLECULAR STRUCTURE FOR SOME DICYCLIC HYDROCARBONS HAVING HIGH THERMAL-ENERGY RELEASE PER UNIT VOLUME-2-ALKYLBIPHENYL AND THE TWO ISOMERIC 2-ALKYLBICYCLOHEXYL SERIES. Irving A. Goodman and Paul H. Wise. 1952. 10p. diagrs., 2 tabs. (NACA Rept. 1065. Formerly TN 2419)

Three homologous series of related dicyclic hydrocarbons are compared on the basis of the following physical properties: net heat of combustion, density, melting point, boiling point, and kinematic viscosity. The three series investigated are the 2-alkylbiphenyl, and the high- and low-boiling 2-alkylbicyclohexyl series through C_{16}. Comparisons are made on the following bases: (1) as members of an homologous series in which the compounds have similar structures and differ in molecular weight; (2) as isomers with the same molecular formula but different molecular structure due to brancning of the side chain or geometrical isomerism; and (3) as compounds with the same carbon skeleton but different molecular formula due to hydrogenation of the aromatic ring.

NACA TN 2743

LANDING-GEAR IMPACT. W. Flügge, Stanford University. October 1952. 91p. diagrs., 9 tabs. (NACA TN 2743)

The report deals with the impact forces in landing gears. Both the landing impact and the taxying impact have been considered, but drag forces have so far been excluded. The differential equations are developed and their numerical integration is shown, considering the nonlinear properties of the oleo shock strut. A way is shown for determining the dimensions of the metering pin from a given load-time diagram. A review of German literature on landing-gear impact is also presented.

NACA TN 2782

BENDING OF THIN PLATES WITH COMPOUND CURVATURE. H. G. Lew, Pennsylvania State College. October 1952. 49p. diagrs., 2 tabs. (NACA TN 2782)

A method is developed for analysis of deformations of doubly curved thin plates under edge or surface loads for small deflections. The problem is approached from thin-shell theory so that the plate is to form part of a shell of revolution. An analytical solution is presented completely for a plate with arbitrary meridian of small curvature loaded by normal edge loads on one pair of opposite edges and numerical calculations are given for the deflection and moment distribution for a particular meridian curve. The method developed may be applied to other problems of bending of doubly curved thin plates under edge or surface loads but the theory is limited to small deflections of the plate considered.

FLOW STUDIES IN THE VICINITY OF A MODIFIED FLAT-PLATE RECTANGULAR WING OF ASPECT RATIO 0.25. William H. Michael, Jr. September 1952. 33p. diagrs., photos. (NACA TN 2790)

Studies were made of the flow in the vicinity of a modified flat-plate rectangular wing of aspect ratio 0.25 by the use of photographs of a tuft grid located at various chordwise positions on the wing and behind the wing, supplemented by wake studies with a yaw-head pitot-tube installation. Evaluations were made concerning the rolling-up of the trailing vorticity, vorticity distribution in the wake, chordwise growth of lift, and locations of the vortex cores.

NACA TN 2794

A COMPARISON OF TWO METHODS OF LINEARIZED CHARACTERISTICS FOR A SIMPLE UNSTEADY FLOW. Roger D. Sullivan. September 1952. 28p. diagrs. (NACA TN 2794)

Two methods of using the concept of linearized characteristics are derived for the one-dimensional unsteady flow in a tube that is rotated about an axis perpendicular to the axis of the tube. One of the methods corresponds to that used by Ferri in his basic work on the subject. Solutions are made by both methods for boundary conditions that allow analytic solutions. Comparisons shows that both methods give the same results but there are significant differences in their application.

NACA TN 2796

EXPERIMENTAL STUDY OF THE EFFECTS OF FINITE SURFACE DISTURBANCES AND ANGLE OF ATTACK ON THE LAMINAR BOUNDARY LAYER ON AN NACA 64A010 AIRFOIL WITH AREA SUCTION. Milton A. Schwartzberg and Albert L. Braslow. October 1952. 35p. diagrs. (NACA TN 2796)

A Langley low-turbulence wind-tunnel investigation of a porous NACA 64A010 airfoil section has been made to determine the effectiveness of area suction in maintaining full-chord laminar flow behind finite disturbances and at angles of attack other than 0°. Area suction resulted in only a small increase in the size of a finite disturbance required to cause premature boundary-layer transition as compared with that for the airfoil without suction. Combined wake and suction drags lower than the drag of the plain airfoil were obtained through a range of low lift coefficient by the use of area suction.

NACA TN 2797

A STUDY OF THE TRANSIENT BEHAVIOR OF SHOCK WAVES IN TRANSONIC CHANNEL FLOWS. Robert V. Hess. October 1952. 32p. diagrs. (NACA TN 2797)

The accuracy of the result obtained in a fundamental paper by Kantrowitz (NACA TN 1225) that a small short-time lowering of the back pressure in steady, shock-free, transonic diffuser flow causes a stationary or trapped shock to form near the critical sonic channel throat is investigated by considering the contribution of a higher-order term in the short-time calculations which was neglected in Kantrowitz's paper. In this higher approximation to the short-time effects, the shock is no longer stationary or trapped unless it is supported by a negative steady-flow back pressure; the result thus is no longer in disagreement with steady-flow solutions for stationary shocks.

NACA TN 2798

AN EXPERIMENTAL INVESTIGATION OF THE BEHAVIOR OF 24S-T4 ALUMINUM ALLOY SUBJECTED TO REPEATED STRESSES OF CONSTANT AND VARYING AMPLITUDES. Herbert F. Hardrath and Elmer C. Utley, Jr. October 1952. 23p. diagrs., 4 tabs. (NACA TN 2798)

A device for adapting R. R. Moore rotating-beam fatigue testing machines for tests in which the amplitude of stress is continuously varied is described. Tests of 24S-T4 aluminum-alloy specimens subjected to stresses of constant amplitude and to stresses with amplitudes varying according to sinusoidal and exponential functions are reported. The results are analyzed by computing the summation of cycle ratios. The values obtained in this analysis were found to be influenced by the shape of the frequency-distribution curve.

NACA TN 2800

SOLUTIONS OF LAMINAR-BOUNDARY-LAYER EQUATIONS WHICH RESULT IN SPECIFIC-WEIGHT-FLOW PROFILES LOCALLY EXCEEDING FREE-STREAM VALUES. W. Byron Brown and John N. B. Livingood. September 1952. 36p. diagrs., 2 tabs. (NACA TN 2800)

Revised solutions of the laminar-boundary-layer equations for cases which involved cooling at the wall combined with large pressure gradients in the main stream produced specific-weight-flow profiles which locally exceeded free-stream values. Heat-transfer and friction coefficients, boundary-layer thicknesses, and velocity, temperature, and specific-weight-flow distributions resulting from the revised solutions are presented for Euler numbers of 0.5 and 1, stream-to-wall temperature ratios of 2 and 4, and cooling-air flow rates through porous walls designated by flow parameters of 0, -0.5, and -1.

NACA TN 2801

INVESTIGATION WITH AN INTERFEROMETER OF THE FLOW AROUND A CIRCULAR-ARC AIRFOIL AT MACH NUMBERS BETWEEN 0.6 AND 0.9. George P. Wood and Paul B. Gooderum. October 1952. 80p. diagrs., photos., tab. (NACA TN 2801)

The flow around a 12-percent-thick circular-arc airfoil at zero incidence was observed by use of an interferometer for small increments of free-stream Mach number from 0.609 to 0.896 with laminar and turbulent boundary layers. Mach number contours in the flow field and Mach number and pressure distributions on the airfoil were obtained. Conditions were determined along and at the bases of the shock waves that interacted with the turbulent boundary layer on the airfoil.

NACA TN 2802

BONDING OF MOLYBDENUM DISULFIDE TO VARIOUS MATERIALS TO FORM A SOLID LUBRICATING FILM. II - FRICTION AND ENDURANCE CHARACTERISTICS OF FILMS BONDED BY PRACTICAL METHODS. Douglas Godfrey and Edmond E. Bisson. October 1952. 16p. diagrs. (NACA TN 2802)

The use of molybdenum disulfide MoS_2 as a solid-film lubricant, in applications where designs or higher temperatures preclude liquid lubricants, is extended because of the good frictional and thermal characteristics of MoS_2. An investigation was conducted to determine (1) practical methods of bonding MoS_2 to materials to form solid-film lubricants and (2) friction and endurance characteristics of films so formed. The results indicated that satisfactory films can be formed by brushing on a mixture of MoS_2 powder and a resin-forming vehicles such as: thinned asphalt-base varnish, silicone-base varnish, or glycerol (1 part, by weight, MoS_2, 2 parts vehicle). Choice of vehicle is governed by application, cleaning, and temperature of curing. Friction and endurance data obtained under high sliding velocities and high surface stress showed that solid-film lubricants (between 0.0002 and 0.0005 in. thick) of MoS_2, bonded with the various resins including corn-syrup resin, resulted in good lubricating effectiveness.

NACA TN 2803

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE INFLUENCE OF TEMPERATURE GRADIENTS ON THE DEFORMATION AND BURST SPEEDS OF ROTATING DISKS. P. I. Wilterdink, A. G. Holms and S. S. Manson. October 1952. 45p. diagrs., photo., 2 tabs. (NACA TN 2803)

The purposes of this investigation were to evaluate the influence of temperature gradients and to test the validity of a recently developed method of calculating plastic flow in disks by comparing the calculated results with experimental observations. Short-time spin tests on parallel-sided, 10-inch-diameter disks were conducted under conditions that subjected the disks to a range of temperatures from 70° to 1440°F. The agreement between the theoretical and experimental results was good over the range of temperature conditions investigated. Temperature gradients produced little reduction in the burst speed of the disks which had a high ductility.

NACA TN 2804

THE PLANING CHARACTERISTICS OF A SURFACE HAVING A BASIC ANGLE OF DEAD RISE OF 20° AND HORIZONTAL CHINE FLARE. Walter J. Kapryan and Irving Weinstein. October 1952. 42p. diagrs., photos., 2 tabs. (NACA TN 2804)

A high-speed investigation was conducted to determine the hydrodynamic characteristics of a planing surface having an angle of dead rise of 20° and horizontal chine flare. The data indicate that the planing characteristics at a given trim depend only on lift coefficient. The ratio of center-of-pressure location to the mean wetted length can be considered approximately equal to 0.67 up to 18° of trim. This ratio decreases with further increase in trim. Pile-up of water at the keel of the model was substantial at trims above 12°. Friction drag is negligible at high trims. The resistances for trims of 18° and higher, therefore, may be assumed equal to the load times the tangent of the trim angle.

NACA TN 2807

MEASUREMENTS OF TEMPERATURE VARIATIONS IN THE ATMOSPHERE NEAR THE TROPOPAUSE WITH REFERENCE TO AIRSPEED CALIBRATION BY THE TEMPERATURE METHOD. Lindsay J. Lina and Harry H. Ricker, Jr. October 1952. 23p. diagrs., tab. (NACA TN 2807)

Measurements of temperature variations in the atmosphere near the tropopause over land in the vicinity of Langley Field, Va., are presented. This investigation was made for the purpose of obtaining information on the accuracy of the temperature method (NACA TN 2046) of airspeed calibration over the range of Mach number from 0.6 to 0.8. The temperature surveys and the description of a specially designed thermometer are also presented.

NACA TN 2808

SHORT-BEARING APPROXIMATION FOR FULL JOURNAL BEARINGS. F. W. Ocvirk. Cornell University. October 1952. 61p. diagrs. (NACA TN 2808)

A short-bearing approximation of pressure distribution in the oil film is presented which is an extension of the pressure-distribution function of Michell and Cardullo and includes end-leakage effects. Equations giving applied load, attitude angle, location and magnitude of peak film pressure, friction, and required oil flow rate as functions of the eccentricity ratio are also given. The capacity number, a basic nondimensional quantity resulting from this analysis, is the product of the Sommerfeld number and the square of the length-diameter ratio. Curves determined by this analysis are compared with previously published experimental data and theoretical curves of Sommerfeld and Cameron and Wood. Conclusions reached indicate that this approximation is of practical value for analysis of short bearings.

ONE-DIMENSIONAL ANALYSIS OF CHOKED-FLOW TURBINES. Robert E. English and Richard H. Cavicchi. October 1952. 53p. diagrs. (NACA TN 2810)

Flow conditions internal to chocked-flow turbines were subjected to a one-dimensional analysis. Factors affecting the design, operation, and manufacture of such turbines were investigated. Criteria are presented which will aid in analysis of test data from such turbines. The effect of turbine-stator adjustment on internal flow conditions was investigated for one application of turbine stator adjustment.

LUMPED REFLECTOR PARAMETERS FOR TWO-GROUP REACTOR CALCULATIONS. Daniel Fieno, Harold Schneider and Robert B. Spooner. September 1952. 25p. diagrs., tab. (NACA RM E52H01)

Equations are developed to show that, for one-dimensional two-group neutron-distribution calculations, the properties of a neutron-reflector region can be combined in three parameters that effectively represent the action of the reflector. The use of these parameters and boundary conditions based on them for single and multizone reflectors is considered and from the results of computations, the following applications of the parameters are shown: (1) Use of the parameters in connection with reactor core properties for comparison of reflector configurations, (2) direct use of parameters as circuit constants in electrical analog, and (3) use of boundary conditions based on reflector parameters to obtain numerical solutions of two-group equations in a neutron-producing region.

INVESTIGATION OF FLOW FLUCTUATIONS AT THE EXIT OF A RADIAL-FLOW CENTRIFUGAL IMPELLER. Joseph T. Hamrick and John Mizisin. October 1952. 20p. diagrs., photo. (NACA RM E52H11)

Surveys were made at the exit of a radial-flow centrifugal impeller to obtain instantaneous values of velocity from blade to blade and at various positions between the front and rear diffuser walls. Surveys were also made at several radial stations midway between the walls of the diffuser to observe the radial change in flow pattern. At the impeller exit, there were variations in velocity patterns across each passage from passage to passage, and for the same passage from revolution to revolution. The general flow patterns persisted into the diffuser and were still evident at a radius 23 percent greater than that of the impeller.

CABIN COOLING FLIGHT TESTS ON A TUDOR 2 AIRCRAFT. D. A. Hancock and T. J. Methven. March 1952. 45p. diagrs., photos., 4 tabs. (RAE Tech. Note Mech. Eng. 118)

This note describes a series of flight tests made on a Tudor 2 aircraft as the first stage of the practical determination of the heat loss or gain of aircraft cabins in flight. The prime object of these tests, which were made with an air cycle refrigerator (type C. A. 7.) fitted to the aircraft ventilation system was to obtain data on cabin cooling; but as the refrigerator installation was fully instrumentated, measurements of its performance were obtained. It was found that owing to the large number of variables present and the difficulty in obtaining identical ambient conditions for any two flights, the results obtained were not completely conclusive. It is possible, however, to make general deductions for this particular aircraft, and to indicate future investigations.

THE PERFORMANCE OF VARIOUS TYPES OF RESISTANCE THERMOMETERS FOR OUTSIDE AIR TEMPERATURE MEASUREMENTS FROM AIRCRAFT. D. C. Austin. April 1952. 17p. photos. (RAE Tech. Note EL. 28)

This note gives results and details of a number of flight tests carried out on eight variations of resistance thermometer installations for measurement of outside air temperature from service aircraft. The purpose of the tests was to determine the most suitable type of installation for general service use and to find an alternative thermometer to the existing flat plate type. The magnitude of the possible error due to the velocity of the aircraft is shown and the method of determining this error is given in detail for

information and also as a basis of comparison with similar tests carried out by other establishments. The errors which arise due to other causes are also detailed to indicate the over-all accuracy which can be expected. The thermometer bulbs tested and their associated indicators constitute systems which are considered suitable for installation in all types of aircraft as distinct from the more precise and accurate thermometric systems installed on meteorological aircraft.

A MODULATOR CIRCUIT OF THE MAGNETIC AMPLIFIER TYPE. J. Baranowski. March 1952. 41p. diagrs. (RAE Tech. Note EL. 34)

A transductor type modulator with two cores and two cooper-oxide rectifiers which gives a duo-directional d-c. output is described. Current gains of 10 to 20 and power gains of up to a thousand are obtained in a single stage and the output may be fed into a similar modulator or into a conventional magnetic amplifier. A 400 c/s three stage amplifier is also described which incorporates two such modulator circuits and which has a power gain of 10^8 (current gain 1000) for a response time of 0.14 sec with a long term zero stability of 2×10^{-11} watt input power. With further development it is considered that this zero stability could be improved, possibly by a factor of 10.

A SIMPLE ESTIMATE OF THE PROFILE DRAG OF SWEPT WINGS. J. Weber and G. G. Brebner. June 1952. 14p. diagrs., tab. (RAE Tech. Note Aero 2168)

It is shown that the profile drag of swept wings near zero lift can be calculated much more simple than might be expected in view of the complicated nature of the three-dimensional boundary layer. Following the approach of Young and Booth, simple charts are derived for obtaining a drag reduction factor due to sweep. The profile drag of a swept wing may be obtained by applying this factor to the results of Squire and Young for two-dimensional airfoils, if the transition position on the swept wing is known. Results of such a calculation are confirmed by experimental data from a 45° sweptback wing of aspect ratio 3.

Royal Aircraft Establishment (Gt. Brit.)
THEORETICAL LOAD DISTRIBUTION ON A WING WITH A CYLINDRICAL BODY AT ONE END. J. Weber. June 1952. 27p. diagrs. (RAE Aero 2467)

A method is derived for calculating the spanwise load distribution over a lifting wing having a long circular-cylindrical body at one end. The solution is derived for arrangements giving minimum induced drag, but can be generalized to obtain approximate results for other plan forms including those with sweepback. Charts are given for the case in which the sectional lift slope is constant along the span. The lift distribution over both wing and body can be determined quickly, or the over-all load obtained directly. The results are applicable to the determination of side forces on a fin in combination with the rear fuselage of an aircraft, or of the lift loading on a wing with a weapon or fuel tank at one tip.

EFFECTS OF MODERATE BIAXIAL STRETCH-FORMING ON TENSILE AND CRAZING PROPERTIES OF ACRYLIC PLASTIC GLAZING. B. M. Axilrod, M. A. Sherman, V. Cohen and I. Wolock, National Bureau of Standards. October 1952. 42p. photos., diagrs., 4 tabs. (NACA TN 2779)

Effects of approximately 50-percent biaxial stretch-forming on the tensile and crazing properties of polymethyl methacrylate were determined. Specimens from formed and unformed pieces of the same sheets were subjected to standard tensile tests, stress-solvent crazing with benzene, long-time tensile loading, and accelerated weathering. Results indicate that biaxial stretch-forming does not affect the tensile strength or modulus of elasticity but does significantly increase the total elongation and strain and stress at the onset of crazing.

NACA TN 2781

THE EFFECTS OF DYNAMIC LATERAL STABILITY AND CONTROL OF LARGE ARTIFICIAL VARIATIONS IN THE ROTARY STABILITY DERIVATIVES. Robert O. Schade and James L. Hassell, Jr. October 1952. 56p. diagrs., photo., 2 tabs. (NACA TN 2781)

The results of an experimental and theoretical investigation of the effects of large artificial variations of four rotary stability derivatives on the dynamic lateral stability and control of a 45° sweptback-wing airplane model are presented. The experimental results are presented mainly in the form of flight ratings for stability, control, and general flight behavior. Calculations of period and damping and of the response to rolling and yawing disturbances are also presented.

NACA TN 2799

SIMPLE GRAPHICAL SOLUTION OF HEAT TRANSFER AND EVAPORATION FROM SURFACE HEATED TO PREVENT ICING. Vernon H. Gray. October 1952. 19p. diagrs. (NACA TN 2799)

Equations expressing the heat transfer and evaporation from wetted surfaces during ice prevention have been simplified and regrouped to permit solutions by simple graphical means. Working charts for quick and accurate anti-icing calculations are also included.

AN ENGINEERING METHOD FOR ESTIMATING NOTCH-SIZE EFFECT IN FATIGUE TESTS ON STEEL. Paul Kuhn and Herbert F. Hardrath. October 1952. 35p. diagrs., 7 tabs. (NACA TN 2805)

Neuber's proposed method of calculating a practical factor of stress concentration for parts containing notches of arbitrary size depends on the knowledge of a "new material constant" which can be established only indirectly. In this paper, the new constant has been evaluated for a large variety of steels from fatigue tests reported in the literature, attention being confined to stresses near the endurance limit; reasonably satisfactory results were obtained with the assumption that the constant depends only on the tensile strength of the steel. Even in cases where the notches were cracks of which only the depth was known, reasonably satisfactory agreement was found between calculated and experimental factors. It is also shown that the material constant can be used in an empirical formula to estimate the size effect on unnotched specimens tested in bending fatigue.

NACA TN 2806

COMPARISON OF TWO- AND THREE-DIMENSIONAL POTENTIAL-FLOW SOLUTIONS IN A ROTATING IMPELLER PASSAGE. Gaylord O. Ellis and John D. Stanitz. October 1952. 61p. diagrs. (NACA TN 2806)

A solution is presented for three-dimensional, incompressible, nonviscous, potential flow in a rotating impeller passage with zero through flow. The solution is obtained for a conventional impeller with straight blades but with the inducer vanes removed and the impeller blades extended upstream parallel to the axis of the impeller. By superposition of solutions two additional examples are obtained for different ratios of compressor flow rate to impeller tip speed. The three-dimensional solutions are compared with corresponding two-dimensional solutions and it is concluded that, at least for the type of impeller geometry investigated, two-dimensional solutions can be combined to describe the three-dimensional flow in rotating impellers with sufficient accuracy for engineering analyses.

NACA TN 2811

ON THE CALCULATION OF FLOW ABOUT OBJECTS TRAVELING AT HIGH SUPERSONIC SPEEDS. A. J. Eggers, Jr. October 1952. 25p. diagrs. (NACA TN 2811)

A procedure for calculating three-dimensional steady and nonsteady supersonic flows with the method of characteristics is developed and discussed. An approximate method is deduced from the characteristics method and shown to be of practical value at high supersonic speeds.

NACA TN 2812

EFFECTS OF CYCLIC LOADING ON MECHANICAL BEHAVIOR OF 24S-T4 AND 75S-T6 ALUMINUM ALLOYS AND SAE 4130 STEEL. C. W. MacGregor and N. Grossman. Massachusetts Institute of Technology. October 1952. 53p. diagrs., photos., 4 tabs. (NACA TN 2812)

An investigation was conducted to determine the effects of cyclic loading on the mechanical behavior of 24S-T4 and 75S-T6 aluminum alloys and SAE 4130 steel. Specimens of the three materials were subjected to various numbers of prior fatigue cycles both below and above the fatigue limits. Special slow-bend tests were employed to show the effects of prior cycles of fatigue stressing on the transition temperature to brittle fracture for SAE 4130 steel and on the energy-absorption capacity of the aluminum alloys. Micrographic studies were made to observe and measure crack formation and propagation and additional special tests were conducted to supplement the results of the slow-bend tests. These included Charpy impact tests, microhardness surveys, tension tests, and fretting-corrosion studies.

NACA TN 2814

THE APPLICATION OF PLANING CHARACTERISTICS TO THE CALCULATION OF THE WATER-LANDING LOADS AND MOTIONS OF SEAPLANES OF ARBITRARY CONSTANT CROSS SECTION. Robert F. Smiley. November 1952. 37p. diagrs. (NACA TN 2814)

The general equations governing the fixed-trim water landing of a straight-keel seaplane of arbitrary constant cross section are presented in such a form that the landing motions and loads are expressed in terms of the steady-planing characteristics of the seaplane. In order to verify the general validity of these equations, solutions are made for the water landing of a rectangular flat plate and are compared with experimental impact data. Calculated and experimental time histories of draft, velocity, and load are in good agreement. A survey is made of the available information on seaplane planing characteristics which is suitable for use with the analysis of the paper.

NACA TN 2818

SECOND APPROXIMATION TO LAMINAR COMPRESSIBLE BOUNDARY LAYER ON FLAT PLATE IN SLIP FLOW. Stephen H. Maslen. November 1952. 38p. diagr., tab. (NACA TN 2818)

The first-order solution for the laminar compressible boundary-layer flow over a flat plate at constant wall temperature is given. The effect of slip at the wall as well as the interaction between the boundary-layer flow and the outer stream flow is taken into consideration. The solution is obtained explicitly in terms of the known zero order, or continuum, solution. No assumptions regarding the Prandtl number or viscosity-temperature law need be made. It is found that the first-order solution gives a decrease in

heat transfer and, for supersonic flow, an increase in skin friction. For subsonic flow there is no first-order shear effect. The change in heat transfer is due to slip and the change in friction is due to the interaction of the zero- and first-order velocities at the outer edge of the boundary layer.

NACA RM 52I09

A METER FOR TIMING THE FLOW OF VERY SMALL VOLUMES OF A GAS. J. C. Westmoreland, National Bureau of Standards. October 1952. 17p. diagrs., photos. (NACA RM 52I09)

A flowmeter has been developed which combines a volume-time measurement of the flow, regulation of the rate, and a determination or presetting of the pressure head producing the flow. This meter is capable of accurately metering and controlling very small rates of gas flow within a closed system such as those required in a small capillary tube gas viscosimeter.

NACA RM E52H26

EFFECT OF GEOMETRY ON SECONDARY FLOWS IN BLADE ROWS. A. G. Hansen, G. R. Costello and H. Z. Herzig. October 1952. 38p. photos. (NACA RM E52H26)

The influence of blade-row geometry on secondary flows in a two-dimensional cascade was investigated qualitatively by varying independently the stagger angle, aspect ratio, solidity, angle of attack, and by providing blade fillets. The influence of tip clearance and relative motion between blades and wall was also studied. Stagger angle and aspect ratio had no appreciable effect on this secondary flow, whereas solidity and angle of attack did affect the flow patterns indicating the turning as a major parameter. Blade-tip clearance induced a vortex produced by flow under the blade end which rotated opposite to the original secondary-flow passage vortex. The clearance vortex displaced but did not reduce the secondary-flow vortex. When the wall was moved relative to the blades, the blade leading surfaces "scraped" up entrained fluid near the wall and imparted a roll up motion to the air in this region. On the trailing surface the fluid was pulled off the blade onto the wall. The magnitude of the scraping effect was so large that it masked completely the secondary-flow and tip-clearance phenomena.

NACA TM 1351

ON THE DESIGN OF AIRFOILS IN WHICH THE TRANSITION OF THE BOUNDARY LAYER IS DELAYED. (Kyōkaiso no Sen'i o okuraseru Yokugata no tuite). Itiro Tani. October 1952. 74p. diagrs., 8 tabs. (NACA TM 1351. Trans. from Aeronautical Research Institute, Tokyo Imperial Univ., Rept. 250, v. 19, no. 1, January 1943).

A method is presented for designing suitable thickness distributions and mean camber lines for airfoils permitting extensive chordwise laminar flow. Wind tunnel and flight tests confirming the existence of laminar flow; possible maintenance of laminar flow by area suction; and the effects of wind tunnel turbulence and surface roughness on the promotion of premature boundary-layer transition are discussed. In addition, estimates of profile drag and scale effect on maximum lift of the derived airfoils are made.

Aeronautical Research Council (Gt. Brit.) NOTE ON SIR GEOFFREY TAYLOR'S CRITERION FOR THE RATE OF BOUNDARY-LAYER SUCTION AT A VELOCITY DISCONTINUITY. N. Gregory. 1952. 12p. diagrs., photo. (ARC R & M 2496. Formerly ARC 10,630; Perf. 326; FM 1112)

Sir Geoffrey Taylor's criterion for the rate of boundary-layer suction at a velocity discontinuity is described, and is compared with experimental results obtained from boundary-layer explorations. It is found that, despite neglect of the pressure gradient due to the curvature of the flow, the criterion gives reasonable estimates of the suction quantity. On the other hand, close agreement with velocity profiles is only obtained when the pressure gradient is taken into account.

Aeronautical Research Council (Gt. Brit.) POSSIO'S SUBSONIC DERIVATIVE THEORY AND ITS APPLICATION TO FLEXURAL-TORSIONAL WING FLUTTER. PART I. POSSIO'S DERIVATIVE THEORY FOR AN INFINITE AEROFOIL MOVING AT SUBSONIC SPEEDS. R. A. Frazer. PART II. INFLUENCE OF COMPRESSIBILITY ON THE FLEXURAL-TORSIONAL FLUTTER OF A TAPERED CANTILEVER WING MOVING AT SUBSONIC SPEED. R. A. Frazer and Sylvia W. Skan. 1951. 22p. diagrs., 5 tabs. (ARC R & M 2553. Formerly ARC 4932; ARC 0.205; ARC 5916; ARC 0.274)

The derivative theory due to C. Possio for an infinite airfoil moving at subsonic speeds is reviewed, and certain modifications are proposed. Derivative values are calculated for a Mach number of 0.7 and for values of the frequency parameter λ ranging from 0 to 5.0. For $\lambda < 1$ the derivative values based on a three-point collocation method are in fair

agreement with those given by Possio. For the range $1.0 < \lambda < 2.0$ five-point collocation is necessary, while for $\lambda = 5.0$ even seven-point collocation may prove unsatisfactory. The numerical results obtained are applied in Part II to estimate the influence of compressibility and flying height on the critical speed for flutter of a tapered cantilever wing.

BOUNDARY-LAYER AND WAKE INVESTIGATION IN SUPERSONIC FLOW. J. Lukasiewicz and J. K. Royle. 1952. 22p. diagrs., photos., 2 tabs. (ARC R & M 2613; ARC 12,130. Formerly RAE Aero 2292; SD 31)

The report describes the results of traverses of the boundary layer and wake encountered in a small supersonic tunnel at a Mach number of 2.5. The tunnel was arranged with two throats in parallel formed by two shaped walls enclosing a shaped central element. Both the laminar and turbulent boundary layers were encountered and compared with existing experimental and theoretical results. The frictional drag of the central element as deduced from the wake traverses is in close agreement with that calculated from considerations of laminar boundary-layer growth over the surface of the element. The tests also provide information relating to the design of nozzle profiles, particularly at the point of inflexion, where the changes of pressure gradient may have a serious effect on the boundary layer and on the velocity distribution.

THE NUMERICAL METHOD OF CHARACTERISTICS FOR HYPERBOLIC PROBLEMS IN THREE INDEPENDENT VARIABLES. C. K. Thornhill. 1952. 13p. diagrs. (ARC R & M 2615; ARC 11,767. Formerly Armament Research Establishment Rept. 29/48; Theoretical Research Rept. 4/48)

Recent advances in electronic computing devices suggest that it may soon be feasible to attempt numerical solutions of problems involving three independent variables. In this paper, preliminary consideration is given to the extension of the numerical method of characteristics for hyperbolic equations to the case of three independent variables. A general quasi-linear second-order partial differential equation in three variables is first considered, and the characteristic surfaces and curves are derived, together with the differential relations which hold along them. It is shown that numerical integration should be possible along the faces or edges of a hexahedral grid. The equations are developed in more detail for two special cases of compressible flow, namely steady isentropic supersonic flow in three-dimensional space, and unsteady flow in two dimensions.

THE FLOW IN AN AXIALLY-SYMMETRIC SUPERSONIC JET FROM A NEARLY-SONIC ORIFICE INTO A VACUUM. P. L. Owen and C. K. Thornhill. 1952. 8p. diagrs. (ARC R & M 2616; ARC 11,768. Formerly Armament Research Establishment Rept. 30/48; Theoretical Research Rept. 5/48)

The numerical method of characteristics is used to calculate the flow in a steady supersonic jet of air issuing from a slightly supersonic circular orifice into a vacuum. The calculations are entirely numerical, and no recourse is made to graphical methods. The characteristic equations for steady supersonic flow with rotational symmetry are first derived, and then special consideration is given to the flow near the axis of symmetry, where the normal step-by-step numerical process breaks down. In the calculation, the Mach angle in the plane of the orifice is taken as 85° to obviate the difficulties of a sonic orifice at which the initial characteristics would be perpendicular to the flow, and the potential equation parabolic. The results should be practically the same as for a sonic orifice. An alternative method of dealing with a sonic boundary plane would have been the use of analytical solutions for the initial flow in this region. The results of the calculations are presented in diagrams. The solution is a universal solution insofar that it applies to any similar jet, flowing into any external pressure, in that region bounded by the orifice and the first wave front which registers the existence of an external pressure outside the jet. This fact allows the calculated pressure distribution along the axis of symmetry to be compared with experimental measurements in air jets with finite pressure ratios, and good agreement is obtained.

Aeronautical Research Council (Gt. Brit.)
A THEORETICAL INVESTIGATION INTO THE LATERAL STABILITY OF AN AEROPLANE CONTROLLED BY AN AUTOMATIC PILOT, WITH PARTICULAR REFERENCE TO THE EFFECT OF FLIGHT PATH ANGLE. T. W. Prescott. 1952. 11p. diagrs. (ARC R & M 2640; ARC 11,409. Formerly RAE Tech. Note IAP 974)

Several autopilots produce aileron deflection proportional to the movement between the airplane and the outer gimbal of a vertical gyroscope. In nonlevel flight, this relative movement is not equal to the rotation of the airplane about its x-axis, and it was desirable to investigate the lateral stability for steep angles of climb and dive. Calculations show that instability does occur, but that stability can be restored either by making the rudder deflection dependent on aileron movement in order to counteract the aileron drag coefficient, or by adding a rate of yaw term to the rudder circuit. The addition of both aileron and rate terms to the rudder circuit is greatly superior to the addition of either term alone. The aileron drag coefficient can also have a detrimental effect at the start of an automatic turn, and response curves during entry into the turn have been calculated for various degrees of aileron drag compensation. The bank angle and sideslip response curves are unaffected by the compensation. The rate of turn response is improved during the first second but subsequently is little affected by aileron drag compensation.

ON A THEORY OF SANDWICH CONSTRUCTION. W. S. Hemp. 1952. 9p. (ARC R & M 2672; ARC 11,568. Formerly College of Aeronautics, Cranfield Rept. 15)

The theory of sandwich construction developed in this paper proceeds from the simple assumption that the filling has only transverse direct and shear stiffnesses, corresponding to its function requirements. This supposition permits integration of the equilibrium equations for the filling. The resulting integrals are used to study the compression buckling of a flat sandwich plate. The formulas obtained are complex, but may be simplified in practical cases. A second approach to sandwich problems is made in section 5, where a theory of "bending" of plates is outlined. This generalizes the usual theory, making allowance for flexibility in shear. This approach is applied to over-all compression buckling of a plate and agreement with the previous calculations is found. This suggests the possibility of calculating buckling loads for curved sandwich shells. A simple example, the symmetrical buckling of a circular cylinder in compression, is worked out. The theory developed would seem applicable to all cases of buckling of not too short a wave length.

SERVICE FAILURES IN AIRCRAFT STRUCTURES ASSOCIATED WITH FATIGUE, REPEATED OR DYNAMIC LOADS. J. B. B. Owen. 1952. 13p. diagrs., photos. (ARC R & M 2688; ARC 9426. Formerly RAE SME 3384)

This note gives examples and photographs of several structural defects which have occurred in service and shows that, although many failures may be due to fatigue or the application of excessive static loads, some are probably influenced by the repeated application of loads of high intensity, and by loads of a dynamic character. It is suggested that changes in design aimed at (1) eliminating the loads causing failure, for example, reducing in one case tab backlash, and (2) alleviating stress concentrations are ways of reducing the incidence of defects due to repeated loading.

NOTES ON HELICOPTER ROTOR BEHAVIOUR AFTER ENGINE FAILURE IN HOVERING FLIGHT. W. Stewart and G. J. Sissingh. 1952. 6p. diagrs. (ARC R & M 2659; ARC 12,525. Formerly RAE Tech. Note Aero 1997)

Calculations have been made of the changes in rotor speed following engine failure on a typical helicopter in hovering flight. Various time functions for the collective pitch operation are considered. The results are in excellent agreement with the one recorded case of an actual power failure in hovering flight. Rapid pilot action in reducing the collective pitch after engine failure is essential to prevent dangerously low rotational speed of the blades. The possibilities of automatic pitch reduction or of a power failure warning to the pilot are considered.

NOTE ON THE APPLICATION OF THWAITES' NUMERICAL METHOD FOR THE DESIGN OF CAMBERED AEROFOILS. A. R. Curtis. 1952. 13p. 6 tabs. (ARC R & M 2665. Formerly ARC 12,154; FM 1336; Perf.531)

Some minor developments in the technique of Thwaites' numerical method of airfoil design are

described. In particular, the process of obtaining the camber-line ordinates from the Goldstein approximation I velocity distribution is discussed in detail; the relevant tables of constants are given. An opportunity is taken to include a complete set of 20-point tables of conjugation factors needed in any actual application of the numerical methods. The theory underlying these tables is given by Watson in R & M 2716.

A THEORETICAL EXAMINATION OF THE EFFECT OF DEADRISE ON WETTED AREA AND ASSOCIATED MASS IN SEAPLANE-WATER IMPACTS. R. J. Monaghan. 1952. 16p. diagrs. (ARC R & M 2681; ARC 12,395. Formerly RAE Tech. Note Aero 1989)

A theoretical examination is made of the dead rise effect on associated mass and wetted area in the two-dimensional impact case (vertical drop of an infinitely long wedge at zero attitude). Available estimates are summarized and a new theoretical formula is developed by means of an expanding prism flow which gives results for associated mass in very close agreement with those given by Wagner's semi-empirical formula (on which most of the estimates of three-dimensional associated mass have so far been based). In addition, the new treatment gives a formula for wetted area which is not available from Wagner's treatment except for very small values of dead rise angle. Comparison is made between these and other formulas in the light both of theory and experiment and a brief survey is made of the assumptions involved in applying associated mass methods to motions through a free surface.

SYSTEMATIC WIND-TUNNEL TESTS WITH SLATS ON A 10 PER CENT THICK SYMMETRICAL WING SECTION (EQ 1040 PROFILE). G. F. Moss. 1952. 22p. diagrs., 6 tabs. (ARC R & M 2705; ARC 12,068. Formerly RAE Aero 2294)

It was thought that present rules for the design of Handley Page slats might be inadequate for modern high-speed airfoil sections. These tests were made on the EQ 1040 wing section to determine the optimum slat setting for this type of wing profile. Three slats were tested whose chords were 10 percent, 20 percent, and 30 percent of the wing chord, over a wide range of positions. Lift coefficients were measured over the stall in each case. Some tests were made with a split flap. Best results for the 10-percent chord slat are obtained with very small gap and large dip. Zero gap, that is, using the slat as a nose flap, may in fact give the optimum. Optimum positions for the larger chord slats are more conventional, but require larger forward extensions than are given by the old rules.

TESTS ON A MODEL BODY-WING COMBINATION AT SUPERSONIC SPEED. P. J. Wingham. 1951. 4p. diagrs. (ARC R & M 2711. Formerly ARC 8229; Ae. 2663; FM 759)

The tests described in this report were made in the 1-foot circular tunnel at the National Physical Laboratory at a Mach number of about 1.4. The main object was to determine the lift obtainable from wings of very short span and in particular to see whether the lift curve departed much from a straight line at incidences up to about 12°, it being already known that the lift curve for a two-dimensional airfoil was sensibly straight up to 20° or so of incidence. Unfortunately it was not possible to measure the drag load, so that only normal-force and pitching-moment values are available.

A METHOD FOR DETERMINING THE WATER STABILITY OF A SEAPLANE IN TAKE-OFF AND LANDING. H. G. White and A. G. Smith. 1952. 17p. diagrs. (ARC R & M 2719; ARC 6834. Formerly MAEE Rept. H/Res/163)

A direct method of determining the water stability in take-off and landing of full-scale seaplanes is described. The customary method of measuring full-scale stability is by steady runs over a range of speed and attitudes. This is tedious; it does not give the true take-off stability and does not give the landing stability. The steady-run stability is assumed to correspond very closely to the take-off stability but was originally used to obtain full-scale conditions comparable with model scale. This report gives a method of analysis of take-off records of attitude against speed, and results obtained by this method are compared with the steady-run results. Results on the Scion fitted with a 1/2-scale Sunderland hull and Saro with a 1/2.75-scale Shetland hull are used to establish the method, but it has also been checked against the available date on the full-scale Seal and Sunderland I. The take-off stability limits show remarkable agreement with the corresponding steady run limits (to within $1/2^{\circ}$) of the Scion and Saro. Evidence on the Seal and Sunderland is insufficient for a definite conclusion in these cases, but there is no disagreement

between the results obtained. The method is accurate and quick to use, but takes no account of the amplitude of porpoising so that a few steady runs would still be necessary to establish this where required. By use of this method, the investigation of the stability characteristics of a seaplane under different conditions of weight, c.g., and flap angle can proceed quickly on the evidence of about eight take-off records at each condition, these records covering the full attitude range. The method may also be applied to find landing stability from landing records.

THE HULL LAUNCHING TANK (DESCRIPTIVE). A. G. Smith, G. C. Abel and W. Morris. 1952. 22p. diagrs., photos. (ARC R & M 2723; ARC 6804. Formerly MAEE Rept.H/Res/161)

The hull launching tank has been built in order that systematic measurements of impact pressures can be made on large model seaplane hulls to supplement full-scale tests, and to cover conditions of impact which would be dangerous full scale. The object is to obtain generalized formulas for the maximum local pressures, the total impact load, and the simultaneous distribution of pressure on any hull form for any impact condition. The report describes the hull launching tank and apparatus, the range of impact conditions possible for test, and the methods developed for measuring the parameters which affect the impact loads. Theoretical considerations, the results of tests and further developments, will be found in existing or in subsequent reports.

SOME ELECTRICAL INTEGRATING CIRCUITS AND THEIR USE IN THE MEASUREMENT OF LOW FREQUENCY VIBRATION AMPLITUDES. G. R. Richards. 1952. 18p. diagrs. (ARC R & M 2724; ARC 11,639. Formerly RAE Tech.Note Instn.121)

The note investigates the possibility of making low frequency vibration measurements by the use of electronic acceleration measuring equipment in conjunction with electrical doubly integrating circuits. It is shown that by this method many of the disadvantages associated with the use of seismic displacement units can be obviated particularly over the frequency range 2 to 40 cps. Three electrical integrating methods are discussed, the correct circuit conditions for the integration of periodic sinusoidal, rectangular and triangular waveforms are derived. A description is given of an existing acceleration measuring equipment incorporating two of the described integration networks; its sensitivity, frequency response, and methods of increasing these factors are discussed in detail.

AN EXPERIMENTAL INVESTIGATION OF THE FLOW THROUGH A HELICOPTER ROTOR IN FORWARD FLIGHT. P. Brotherhood and W. Stewart. 1952. 12p. diagrs., photos. (ARC R & M 2734; ARC 12,894. Formerly RAE Aero 2330)

Experiments have been made to determine the flow conditions through a helicopter rotor in forward flight using the smoke filament technique. This method consisted of flying the helicopter behind an aircraft from which smoke generators were suspended on a long wire. The smoke trails passed through the main rotor of the helicopter, and photographs were taken from another aircraft in a side position. Flow conditions at the rotor disk over a narrow bend on the side of the advancing blade were investigated in this way. The range of speeds covered was from 44 mph to 60 mph corresponding to a range of tip speed ratios 0.138 to 0.188. An increase in induced velocity from front to rear of the rotor disk was obtained. The results are in reasonable agreement with theoretical predictions.

Forest Products Research Lab. (Gt. Brit.)
REVISED MANUAL FOR CONDUCTING TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE.
R. A. G. Knight. June 1952. ii, 14p. (Forest Products Research Lab. PRP 8/1)

The Composite Wood Section of the Forest Products Research Laboratory is completely equipped with machinery and plant for the manufacture of plywood of all types. The peeler will take billets up to 5 ft 6 in. long and 4 ft 6 in. diameter and the press will make boards up to 5 ft square. With equipment of this scale, an appraisal can be made of the value of a timber for plywood manufacture, and problems at any stage of the process can be investigated under conditions comparable with those in commercial factories - but distinct from them in that the needs of continuous production are absent. These investigations are made to a prescribed plan so as to apply uniform standards to all timbers, and the results are issued by the Laboratory as Progress Reports in the series "Trials of Timbers for Plywood Manufacture." The plan was originally prepared in collaboration with the Plywood Research Panel, and circulated as Paper P. R. P. 5/1, "Manual for Conducting Trials of Timbers for Plywood Manufacture" in August 1950. After experience with the Manual in tests on 26 species, the Panel saw that improvements could be made that would simplify the work and increase the practical value of the data obtained, so the present Revised Manual was then compiled. The original Paper P. R. P. 5/1 is applicable to reports up to No. 15, but for No. 16 and onwards, the methods of P. R. P. 8/1 apply. The changes are not such as to nullify comparison between the earlier and later reports.

Ministry of Supply (Gt. Brit.)
DEVELOPMENT OF A PRE-STALL DETECTOR FOR AIRCRAFT. R. T. Youngman. July 1952. 7p. diagrs. (MOS S & TM 6/52)

This report describes a stall warning detector which has been developed by the Ministry of Supply. It depends for its operation upon the pressure changes which occur on the undersurface of a wing. At certain points, the pressure increases at a fairly constant rate with increase in angle of incidence. A detector which operates on this principle has the advantage that there are no external parts.

N-17726*

Royal Aircraft Establishment (Gt. Brit.)
FATIGUE PROPERTIES AT LOW TEMPERATURE ON TRANSVERSE AND LONGITUDINAL NOTCHED SPECIMENS OF D. T. D. 363A ALUMINIUM ALLOY. N. J. F. Gunn. June 1952. 23p. diagrs., photo., 11 tabs. (RAE Tech. Note Met. 163)

Tests have been made to ascertain the effect of a specified subnormal temperature (-40° C) on the notched and unnotched fatigue strength of the material. The test pieces were machined from a 5-inch diameter, extruded D. T. D. 363A bar so that their axes coincided with the longitudinal and transverse directions of the parent bar. The results of the tests showed that some increase in fatigue strength is evident at -40° C for longitudinal specimens but no appreciable change for transverse specimens is apparent.

NACA Rept. 1050

FORMULAS FOR THE SUPERSONIC LOADING, LIFT AND DRAG OF FLAT SWEPT-BACK WINGS WITH LEADING EDGES BEHIND THE MACH LINES. Doris Cohen. 1951. iii, 40p. diagrs. (NACA Rept. 1050)

The method of superposition of linearized conical flows has been applied to the calculation of the aerodynamic properties, in supersonic flight, of thin flat, swept-back wings at an angle of attack. The wings are assumed to have rectilinear plan forms, with tips parallel to the stream, and to taper in the conventional sense. The investigation covers the moderately supersonic speed range where the Mach lines from the leading-edge apex lie ahead of the wing. The trailing edge may lie ahead of or behind the Mach lines from its apex. The case in which the Mach cone from one tip intersects the other tip is not treated. Formulas are obtained for the load distribution, the total lift, and the drag due to lift. For the cases in which the trailing edge is outside the Mach cone from its apex (supersonic trailing edge), the formulas are complete. For the wing with both leading and trailing edges behind their respective Mach lines, a degree of approximation is necessary. It has been found possible to give practical formulas which permit the total lift and drag to be calculated to within 2 or 3 percent of the accurate linearized-theory value. The local lift can be determined accurately over most of the wing, but the trailing-edge-tip region is treated only approximately. Charts of some of the functions derived are included to facilitate computing, and several examples are worked out in outline.

NACA Rept. 1063

AIRFOIL PROFILES FOR MINIMUM PRESSURE DRAG AT SUPERSONIC VELOCITIES-GENERAL ANALYSIS WITH APPLICATION TO LINEARIZED SUPERSONIC FLOW. Dean R. Chapman. 1952. ii, 14p. diagrs. (NACA Rept. 1063. Formerly TN 2264)

A derivation is presented of the basic equations which determine the supersonic airfoil profile having minimum pressure drag for certain prescribed structural requirements. The basic equations are applicable to a variety of practical structural requirements, and can be used with either linear, second order, or shock-expansion airfoil theory. A solution of the basic equations is found in closed form using linear airfoil theory. The results show that in most cases the optimum profile has a blunt trailing edge. The optimum distribution of thickness depends on the Mach number, airfoil-thickness ratio, and base pressure coefficient. The pressure drag of the optimum profile is compared to that of the biconvex and double-wedge profiles. A graphical method of determining an optimum airfoil is developed and applied to several examples.

NACA Rept. 1067

GENERALIZATION OF BOUNDARY-LAYER MOMENTUM-INTEGRAL EQUATIONS TO THREE-DIMENSIONAL FLOWS INCLUDING THOSE OF ROTATING SYSTEM. Artur Mager. 1952. ii, 16p. diagrs. (NACA Rept. 1067. Formerly TN 2310).

Boundary-layer equations for application in three-dimensional flows are developed. With the use of a fixed velocity profile and an empirical friction law an approximate solution in closed integral form is obtained for a generalized boundary-layer momentum-loss thickness and flow deflection at the wall in the turbulent case. A numerical evaluation of this solution carried out for data obtained in a curving non-rotating duct shows a fair quantitative agreement with the measured values.

NACA TN 2809

EXPERIMENTAL INVESTIGATION OF ECCENTRICITY RATIO, FRICTION, AND OIL FLOW OF SHORT JOURNAL BEARINGS. G. B. DuBois and F. W. Ocvirk, Cornell University. November 1952. 79p. diagrs., photos., 4 tabs. (NACA TN 2809)

An experimental investigation was conducted to obtain performance data on bearings of length-diameter ratios of 1, 1/2, and 1/4 for comparison with theoretical curves. A 1.375-inch-diameter bearing was tested at speeds up to 6000 rpm and with unit loads from 0 to 900 pounds per square inch. Experimental data for eccentricity ratio and friction followed single lines when plotted against a theoretically derived capacity number, which is equal to Sommerfeld number times the square of the length-diameter ratio. The form of the capacity number indicates that under certain conditions the eccentricity ratio is theoretically independent of bearing diameter. A method of plotting oil flow data as a single line is shown. Methods are also discussed for approximating a maximum bearing temperature and evaluating the effect of deflection or misalinement on the eccentricity ratio at the ends of the bearings.

NACA TN 2813

THEORY AND PROCEDURE FOR DETERMINING LOADS AND MOTIONS IN CHINE-IMMERSED HYDRODYNAMIC IMPACTS OF PRISMATIC BODIES. Emanuel Schnitzer. November 1952. 51p. diagrs. (NACA TN 2813)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A theoretical method is derived for computing the motions and hydrodynamic loads during water landings of prismatic bodies involving appreciable immersion of the chines. A simplified method of computation covering flat-plate and V-bottom bodies with beam-loading coefficients greater than unity is given as a separate section. Comparisons of theory with experiment are presented as plots of impact lift coefficient and maximum draft-beam ratio against flight-path angle and as time histories of loads and motions. Fair agreement is found to exist for chine-immersed landings for angles of dead rise of 0° and 30°, beam-loading coefficients from 1 to 36.5, flight-path angles from 2° to 90°, and trims from 6° to 45°.

NACA TN 2815

A THEORETICAL INVESTIGATION OF THE EFFECT OF PARTIAL WING LIFT ON HYDRODYNAMIC LANDING CHARACTERISTICS OF V-BOTTOM SEAPLANES IN STEP IMPACTS. Joseph L. Sims and Emanuel Schnitzer. November 1952. 20p. diagrs. (NACA TN 2815)

A theoretical investigation is made of the loads and motions in water-landing impacts of wide prismatic V-bottom seaplanes for constant partial wing-lift conditions where the resultant velocity of the seaplane is normal to the keel. An approximate method is given for applying the results of this investigation to the more general case of oblique impact. The increase in vertical hydrodynamic load factor due to wing-lift reduction is shown to be approximately 133 percent of the decrease in air load.

NACA TN 2816

WATER-PRESSURE DISTRIBUTIONS DURING LANDINGS OF A PRISMATIC MODEL HAVING AN ANGLE OF DEAD RISE OF $22\text{-}1/2^{\circ}$ AND BEAM-LOADING COEFFICIENTS OF 0.48 AND 0.97. Robert F. Smiley. November 1952. 37p. diagrs., 6 tabs. (NACA TN 2816)

As part of an over-all program, smooth-water landing tests of a prismatic float having an angle of dead rise of $22\text{-}1/2^{\circ}$ were made. Water-pressure, velocity, draft, and acceleration data are presented. Landings were made for beam-loading coefficients of 0.48 and 0.97 at fixed trims between 0.2° and 30.3° for a range of flight-path angles from 4.6° to 25.9° and also for 90°. The experimental pressure distributions are found to be in fair agreement with the predictions of the available theory; however, better agreement is obtained by modification of the theory.

NACA TN 2817

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF YAW ON PRESSURES, FORCES, AND MOMENTS DURING SEAPLANE LANDINGS AND PLANING. Robert F. Smiley. November 1952. 98p. diagrs., 7 tabs. (NACA TN 2817)

A theory for the side force, rolling moment, yawing moment, and pressure distribution during yawed landings and planing of seaplanes was developed. For the special case of the straight-sided wedge without chine immersion, the results of the theoretical analysis are presented in the form of generalized curves covering all step landing conditions. Experimental impact and planing data are presented for a prismatic wedge having an angle of dead rise of 22.5° and are shown to be in reasonable agreement with the theoretical predictions.

NACA TN 2819

EFFECT OF HIGH-LIFT DEVICES ON THE STATIC-LATERAL-STABILITY DERIVATIVES OF A 45° SWEPTBACK WING OF ASPECT RATIO 4.0 AND TAPER RATIO 0.6 IN COMBINATION WITH A BODY. Jacob H. Lichtenstein and James L. Williams. November 1952. 50p. diagrs., photos., 5 tabs. (NACA TN 2819)

This paper contains the results of wind-tunnel tests to determine the effects of plain and split trailing-edge flaps, with and without leading-edge slats, on the low-speed static-lateral-stability derivatives of a 45° sweptback-wing—body configuration. Comparisons between the increments obtained from experiment and those evaluated by simple sweep theory in combination with measured lift and drag increments are also made.

NACA TN 2820

AN ANALYSIS OF THE ERRORS IN CURVE-FITTING PROBLEMS WITH AN APPLICATION TO THE CALCULATION OF STABILITY PARAMETERS FROM FLIGHT DATA. Marvin Shinbrot. November 1952. 29p. diagrs., 2 tabs. (NACA TN 2820)

The problem of assessing the errors in the parameters obtained from a curve-fitting process is considered, and a scheme which may be applied toward the solution of such problems is obtained. This method is then specialized to the problem of finding the errors in the calculated stability parameters of an airplane, and an example is given.

NACA TN 2821

TORSION TESTS OF ALUMINUM-ALLOY STIFFENED CIRCULAR CYLINDERS. J. W. Clark and R. L. Moore, Aluminum Company of America. November 1952. 38p. diagrs., photos., 2 tabs. (NACA TN 2821)

Results are presented for the second series of torsion tests on aluminum-alloy stiffened circular cylinders, the first series having been reported in NACA ARR 4E31. The cylinders were similar in construction except that the wall thickness was 0.020 inch for the first series and 0.032 inch for the second series. The significant observation from both series of tests are summarized and some comparisons are made with more recent theoretical work.

NACA TN 2823

LANGLEY FULL-SCALE-TUNNEL INVESTIGATION OF THE MAXIMUM-LIFT AND STALLING CHARACTERISTICS OF A TRAPEZOIDAL WING OF ASPECT RATIO 4 WITH CIRCULAR-ARC AIRFOIL SECTIONS. Roy H. Lange. November 1952. 24p. diagrs., photos. (NACA TN 2823. Formerly RM L7H19)

Results are given of an investigation at high Reynolds numbers and low Mach numbers to determine the maximum-lift and stalling characteristics of a trapezoidal wing of aspect ratio 4 with 10-percent-thick, circular-arc airfoil sections. The tests included measurements of the lift, the drag, and the pitching-moment coefficients of the basic wing and of the wing with 0.20-chord droop-nose and trailing-edge flaps deflected both alone and in various combinations. Scale effects were investigated at Reynolds number ranging from 3.27×10^6 to 7.67×10^6.

NACA TN 2824

EFFECTS OF INDEPENDENT VARIATIONS OF MACH NUMBER AND REYNOLDS NUMBER ON THE MAXIMUM LIFT COEFFICIENTS OF FOUR NACA 6-SERIES AIRFOIL SECTIONS. Stanley F. Racisz. November 1952. 32p. diagrs., 2 tabs. (NACA TN 2824)

The NACA 65-006, 64-009, 64-210, and 64_2-215 airfoil sections were tested in the Langley low-turbulence pressure tunnel to determine the effects of independent variations of Mach number and Reynolds number on the maximum-lift characteristics for the smooth and rough conditions. The lift characteristics were determined at constant Reynolds numbers ranging from 1.5×10^6 to 9.0×10^6 for Mach numbers which varied from 0.1 to approximately 0.5 for each Reynolds number.

NACA TN 2825

A COMPARATIVE EXAMINATION OF SOME MEASUREMENTS OF AIRFOIL SECTION LIFT AND DRAG AT SUPERCRITICAL SPEEDS. Gerald E. Nitzberg and Stewart M. Crandall. November 1952. 30p. diagrs. (NACA TN 2825)

Systematic trends in the lift- and drag-coefficient variation with Mach number for a number of relatively thick airfoil sections at moderately supercritical speeds are pointed out. Shortcomings of transonic similarity rules are discussed and a semi-empirical correlation of drag data is presented. Differences between the drag curves for various airfoils are reduced by basing drag coefficient on total pressure rather than dynamic pressure. The initial supercritical loss of lift of airfoil sections having supersonic flow over the upper surface only is shown to result primarily from pressure changes on the lower surface.

NACA TN 2826

SIMULATION OF LINEARIZED DYNAMICS OF GAS-TURBINE ENGINES. J. R. Ketchum and R. T. Craig. November 1952. 25p. diagrs., photo. (NACA TN 2826)

A general method of simulation is presented, whereby linearized dynamics of gas-turbine engines may be simulated in most orderly fashion with greatest economy of equipment and with most direct use of engineering data. Correlation of experimental and simulated responses of a turbojet engine are shown. Use of generalization factors in determining the coefficients necessary for simulation of engine dynamics is discussed.

NACA TN 2827

INVESTIGATION OF A DIFFRACTION-GRATING INTERFEROMETER FOR USE IN AERODYNAMIC RESEARCH. James R. Sterrett and John R. Erwin. November 1952. 36p. photos., diagrs. (NACA TN 2827)

A low-cost interferometer that is easy to adjust and has a large field of view is described. This instrument, which is based on a principle discovered by Kraushaar, uses small diffraction gratings to produce and recombine separate beams of light. The usual two-parabolic-mirror schlieren system can be converted inexpensively into a diffraction-grating interferometer. Experimental data are presented to verify the ability of the instrument to provide valid and reliable measurements of air density. Photographs of the flow in a supersonic cascade tunnel are included to indicate the quality of the interferograms obtained.

NACA TN 2828

EFFECT OF A FINITE TRAILING-EDGE THICKNESS ON THE DRAG OF RECTANGULAR AND DELTA WINGS AT SUPERSONIC SPEEDS. E. B. Klunker and Conrad Rennemann, Jr. November 1952. 26p. diagrs. (NACA TN 2828)

The effect of a finite trailing-edge thickness on the pressure drag of rectangular and delta wings with truncated diamond-shaped airfoil sections with a given thickness ratio is studied for supersonic Mach numbers, linearized theory being used to evaluate the surface pressures. In order to facilitate comparison with wings having sharp trailing edges, the position of maximum thickness and base height are determined for least pressure drag as functions of a base-pressure parameter. Comparison is then made between the drag of these wings and similar wings with a sharp trailing edge for various aspect ratios and thickness ratios as a function of stream Mach number. The calculations of the drag characteristics for these wings show that significant drag reductions are possible under some conditions at high supersonic speeds. These reductions are relatively independent of aspect ratio for the rectangular wings but depend considerably on aspect ratio for the delta wings; the smaller aspect ratios show the larger drag reductions. Calculations of the spanwise distribution of drag are included to compare further the effect of a base on the drag for different aspect ratios.

NACA TN 2829

EXPERIMENTS ON TRANSONIC FLOW AROUND WEDGES. George P. Wood. November 1952. 34p. diagrs., photos., tab. (NACA TN 2829)

Several aspects of transonic flow around the forward portions of wedge profiles were studied by means of interferometry. Measurements were made of the two kinds of flow pattern that occur at the leading edge of a wedge at an angle of attack. The growth of the supersonic region at a sharp convex corner formed by two flat surfaces was observed. The pressure-drag coefficients of a wedge of 14.5° semi-angle were measured at Mach numbers of 0.768, 0.819, and 0.854 and were shown to be consistent with those of wedges of smaller angle when plotted according to the transonic similarity law. Conditions at the bases of the shock waves that interacted with boundary layers on the wedge were measured. The method of characteristics was used to calculate the flow behind an experimentally determined sonic line, and the calculated flow field was compared with the measured flow field. The accuracy in the location of the sonic line necessary to give correctly the pressure distribution on the surface behind it was determined.

NACA TN 2830

SEVERAL COMBINATION PROBES FOR SURVEYING STATIC AND TOTAL PRESSURE AND FLOW DIRECTION. Wallace M. Schulze, George C. Ashby, Jr. and John R. Erwin. November 1952. 64p. diagrs., photos., tab. (NACA TN 2830)

An investigation has been conducted to provide a basis for design of combination probes intended to survey static and total pressure and direction of flow with special reference to subsonic turbomachine testing. Static-pressure probes, yaw-element probes, claw-type yaw probes, and combination probes were tested in an 8-inch-diameter calibration tunnel at air velocities up to 445 feet per second. From the results of this investigation, the factors which determine the sensitivity of claw-type yaw probes were determined. Satisfactory combination survey probes for sensing static and total pressure and direction of flow in one or two planes were devised.

NACA TN 2834

FLOW SURFACES IN ROTATING AXIAL-FLOW PASSAGES. John D. Stanitz and Gaylord O. Ellis. November 1952. 31p. diagrs. (NACA TN 2834)

In order to investigate the deviation of flow surfaces from their assumed orientation in the usual type of two-dimensional solution, three-dimensional, incompressible, nonviscous, absolute irrotational fluid motion is determined for flow through rotating axial-flow passages bounded by straight blades of finite spacing and infinite axial length lying on meridional planes. Solutions are obtained for five passages with varying blade spacing and hub-tip ratio. The results are presented in such a manner as to apply for all ratios of axial velocity to passage tip speed. It is concluded that, for conditions in typical axial-flow blade rows, the deviation of flow surfaces from their assumed orientation in two-dimensional solutions is small.

NACA TN 2835

EFFECT OF CHANGING PASSAGE CONFIGURATION ON INTERNAL-FLOW CHARACTERISTICS OF A 48-INCH CENTRIFUGAL COMPRESSOR. II - CHANGE IN HUB SHAPE. John Mizisin and Donald J. Michel. November 1952. 35p. diagrs., photo., tab. (NACA TN 2835)

The passage contour of a 48-inch centrifugal compressor was modified by changing the shape of the hub to control the deceleration rates along the blade surfaces in order to improve the internal efficiency of the impeller. A comparison of internal-flow characteristics at design flow rate was made with the original impeller and with a modified-blade impeller that had the same area variation in the passage. In addition, flow characteristics of the modified-hub impeller over a flow range from maximum flow to near surge at a corrected tip speed of 700 feet per second are presented. At design flow, even though the deceleration rate along the trailing face was less for the modified-hub impeller than for the original impeller, the clearance losses (increased by the larger ratio of clearance to passage height) caused the total-pressure losses (and thus the relative adiabatic efficiency) to be about the same at the impeller exit for the two configurations, thus precluding any improvement in over-all performance. As in the original modified-blade impellers, large losses occurred at the driving-face inlet at negative angles of attack and in regions of large decelerations along the trailing-face flow surface.

NACA RM 52I25

TORSION, COMPRESSION, AND BENDING TESTS OF TUBULAR SECTIONS MACHINED FROM 75S-T6 ROLLED ROUND ROD. R. L. Moore and J. W. Clark, Aluminum Company of America. November 1952. 33p. diagrs., photos., 4 tabs. (NACA RM 52I25)

Tests were made of tubular sections machined from 75S-T6 aluminum-alloy rolled rod and having ratios of tube diameter to wall thickness D/t ranging from 2 to 150. The purpose of the investigation was to establish curves of strength in torsion, compression, and bending against D/t for the tubular sections and to show to what extent these strengths may be correlated with the mechanical properties of the material. In view of the acceptable mechanical properties obtained for the material, the relations obtained between these strengths and D/t may be used as a tentative basis for design of members of the type investigated.

NACA RM E52I09

EFFECT OF RADIANT ENERGY ON VAPORIZATION AND COMBUSTION OF LIQUID FUELS. A. L. Berlad and R. R. Hibbard. November 1952. 46p. diagrs., 2 tabs. (NACA RM E52I09)

The radiative processes involved in combustion were investigated to determine the present role of radiant energy transfer in combustors. It was shown that at present the amount of radiant energy transfer from flame to fuel is quite small in a turbojet combustor. In order to find techniques for making this radiant energy transfer from flame to fuel significant, methods of increasing the equivalent gray-body emissivities of the fuel drops and the flame, as well as the efficiency of the energy transfer itself, were examined. The equivalent gray-body emissivity of a hydrocarbon fuel may be increased by the use of liquid or solid, soluble or nonsoluble, additives. It was found that the nonsoluble solid additive was the most desirable one. In addition to the fact that a slurry-type drop may have a greater emissivity, the suspended solid additive may also greatly contribute to the emissivity of the flame. An approximate equation was derived from which the equivalent gray-body emissivities of such slurry-type drops may be calculated. Data necessary for these calculations were obtained by spectrophotometric analysis of thin slurry films. In addition to the fuel additive, the use of radiation-reflecting walls in a combustor was considered as a means of maintaining the efficiency of the radiative transfer of energy from flame to fuel drop. It was then shown that more than half the heat of evaporation of the hydrocarbon constituent of this slurry-type drop might be supplied by radiant energy transfer in such a modified turbojet combustor.

NACA RM E52I26

EXAMINATION OF SMOKE AND CARBON FROM TURBOJET-ENGINE COMBUSTORS. Thomas P. Clark. November 1952. 12p. photos., 2 tabs. (NACA RM E52I26)

Smoke and carbon from turbojet-engine combustors were studied by the methods of electron microscopy, chemical analysis, and X-ray diffraction. The smoke exhausting from a combustor was found to consist of carbon black, agglomerated into soot. The carbon black had been partially burned in its passage through the flame zone. The smoke resulted from the incomplete combustion of the vaporized fuel; it was not the result of the pyrolysis of fuel droplets. The soft carbon in the dome of the combustor liner was found to consist of carbon black and soot intermixed with indeterminate complexes such as high-boiling fuel ends and partly polymerized and pyrolyzed heavy hydrocarbons. The hard carbon on the walls of the combustor liner was found to be largely a petroleum coke. The coke was apparently formed by the liquid phase cracking, pyrolysis, and subsequent coking on the liner wall of fuel from the spray nozzle.

MEASUREMENT OF THE MOISTURE CONTENT OF HIGH PRESSURE OXYGEN FOR USE IN AIRCRAFT. II. A HIGH PRESSURE HYGROMETER. M. E. Bedwell and W. G. Glendinning. May 1952. 18p. diagrs., 3 tabs. (RAE Tech. Note Chem. 1175)

The gas flow bridge principle has been used in designing an all-metal hygrometer to measure the moisture content of oxygen gas at transport cylinder pressure. The method could be applied to a producing plant, to give a warning if the moisture content of the gas exceeded the maximum permitted in the specification. Both glass-capillary and metal-capillary bridges have given satisfactory results at pressures approaching that of the atmosphere. A magnetically operated pressure sensitive device has been made to function at the pressure-differential available, but would not operate in the bridge because of slight gas-leakage past the float, which upset the bridge off-balance.

FREE STREAMLINE JETS IN SHEAR FLOW, AND THEIR APPLICATION TO THE DESIGN OF SUCTION SLOTS. W. T. Lord. June 20, 1950. 79p. diagrs. (ARC 13,197; FM 1450)

Solutions for the shapes of free streamline jets issuing from a gap between two flat parallel surfaces may serve as a basis for designing slots for sucking away the boundary layer on an airfoil. A brief description is given of some unsuccessful attempts to obtain analytical solutions for such jets when the flat surfaces are collinear and the flow at a large distance from the gap is a constant shearing motion containing vorticity of any magnitude. A method of solution for the case when the magnitude of the vorticity is sufficiently small for terms of the order of its square and higher powers to be neglected is given in detail. This method may be extended to cover the more general case when there is a step between the flat surfaces on each side of the gap.

INCOMPRESSIBLE TWO-DIMENSIONAL FLOW OF AN INVISCID FLUID ABOUT A SYMMETRICAL AEROFOIL IN A CHANNEL OR FREE STREAM. L. C. Woods. July 7, 1950. 32p. diagrs., 6 tabs. (ARC 13,240; FM 1456)

The paper introduces a new and exact method of calculating the incompressible, inviscid flow about a symmetrical two-dimensional airfoil at zero incidence. The asymmetric case and the effect of circulation will be dealt with a subsequent paper. The method gives velocities throughout the field and is much quicker than the "relaxation" methods that have been applied to this problem. The principle is to replace the airfoil by a series of small arcs on which it is assumed that the product of the radius of curvature and the velocity is constant. It is almost equivalent to replacing the airfoil by a many sided polygon for, at some distance from the airfoil, the field due to a polygon and that due to a profile composed of arcs as defined above, is sensibly the same. Each arc, of course, must cover the same range as the corresponding side of the polygon. The method is termed "The Polygon Method." The idealization takes place in the plane in which the airfoil is represented by a slit, that is, the flow plane. The fields due to each of these arcs are added to give the combined field due to the idealized airfoil. The number of arcs selected to replace the airfoil is governed by the accuracy required in the final results. In the typical example given at the end of the paper, the author found that 12 arcs were sufficient to give accuracies better than 1 percent in the velocity increment due to the airfoil. In a later paper, the method will be extended to obtain an approximate solution of compressible flow, the accuracy of which is a little better than that of the well-known Kármán-Tsien approximation.

Aeronautical Research Council (Gt. Brit.)
AN EXACT FOURIER SERIES METHOD OF CALCULATING THE TWO-DIMENSIONAL INCOMPRESSIBLE FLOW ABOUT AN ASYMMETRICAL AEROFOIL. L. C. Woods. October 12, 1950. 6p. diagrs. (ARC 13,440; FM 1484; Oxford Univ., Engineering Lab. No. 46)

A method of calculating the flow about an asymmetric airfoil at incidence in a free stream is developed. It involves the calculation of a number of Fourier series, the constants of which rapidly converge to zero. The flow about an asymmetric airfoil at incidence in a channel is tackled by an iterative process which the author expects to be rapidly convergent. Separate solutions are obtained in the two regions separated by the stagnation streamlines and are modified step by step until they match along these streamlines.

THERMODYNAMIC PROPERTIES OF AIR AND COMBUSTION PRODUCTS OF HYDROCARBON FUELS, PART II. D. Fielding and J. E. C. Topps. July 1952. 72p. diagrs., 7 tabs. (NGTE R. 120)

This report is a continuation of NGTE Report No. R. 74, giving methods whereby the data required for gas turbine performance calculations, using any fuel or supporter of combustion, may be rapidly computed. The principle of the method given is the addition of a calculated quantity to the corresponding value of the property for dry air, so numerical consistency is automatically ensured. The theory from which the corrections are deduced is given fully, and functions have been computed permitting determination of the true specific heat, the total heat and the entropy function of the combustion products of all common fuel-medium mixtures. The thermodynamic aspects of the combustion process are examined and parameters for the calculation of combustion temperature rise are deduced, and calculated functions are given which permit this determination for any fuel and any atmosphere. The data and methods are suitable for the computation of working data sheets, or for the direct determination of gas turbine performance. Examples of the latter are given, also nomographic aids. Special calculations are discussed, and methods are developed whereby data may be prepared for systems involving further elements or compounds, combustible or otherwise, in the fuel or atmosphere.

NACA RM 8I07

RESPONSE OF A ROTATING PROPELLER TO AERODYNAMIC EXCITATION. Walter E. Arnoldi, Hamilton Standard Propellers Division, United Aircraft Corporation. January 21, 1949. 26p. diagrs. (NACA RM 8I07) (Declassified from Restricted, 9/16/52)

This report presents a theoretical analysis of the flexural vibration of an aircraft propeller blade subjected to harmonic aerodynamic exciting forces at a fixed multiple of propeller rotation frequency. The flexural vibration of a rotating propeller blade with clamped shank is analyzed with the object of presenting, in matrix form, equations for the elastic bending moments in forced vibration resulting from aerodynamic forces applied at a fixed multiple of rotational speed. Matrix equations are also derived which define the critical speeds and mode shapes for any excitation order and the relation between critical speed and blade angle.

NACA RM E7H21

PRELIMINARY INVESTIGATION OF HYDRAZINE AS A ROCKET FUEL. Paul M. Ordin, Riley O. Miller and John M. Diehl. May 24, 1948. 35p. diagrs., photos. (NACA RM E7H21) (Declassified from Confidential, 9/16/52)

Several properties of hydrazine were investigated. Theoretical calculations were made of performance of hydrazine with liquid 0_3, liquid 0_2, H_20_2, and $HN0_3$. Hydrazine is poisonous, decomposes some materials, is temperature sensitive, does not propagate detonation waves, reacts violently with H_20_2, $NaMn0_4$, $C(N0_2)_4$, and $HN0_3 \cdot N0_2$, and gives high theoretical performance with several oxidants.

NACA RM L6L11

WIND-TUNNEL INVESTIGATION OF WING INLETS FOR A FOUR-ENGINE AIRPLANE. Walter A. Bartlett, Jr. and Edwin B. Goral. March 11, 1947. 65p. diagrs., photos., 7 tabs. (NACA RM L6L11) (Declassified from Restricted, 9/16/52)

An investigation has been conducted in the Langley propeller-research tunnel to develop wing-leading-edge inlets for location between the inboard and outboard nacelles on each wing of a four-engine airplane for the Army Air Forces. The investigation included aerodynamic tests of the basic wing and the original inlet, and the development by the NACA of wing inlets for two versions of the airplane. The original inlet was found to decrease the maximum lift coefficients and to have critical Mach numbers below those of the wing with the basic nose installed. The total-pressure recovery in the oil-cooler ducts was poor regardless of the inlet installation. As the sharp expanding bend in this duct cannot be avoided, it is recommended that the oil-cooler air be induced through the cowling or from some source other than the subject wing inlet. Two inlets were developed that should be satisfactory for the airplane. The maximum lift coefficients for the model with inlets 5 and 6 installed were about 1.21 and 1.22, respectively, with 0° wing flaps and 1.87 and 2.00, respectively, with 65° wing flaps compared to corresponding values of 1.20 and 2.01 for the model equipped with the faired basic nose. The predicted critical Mach numbers for inlets 5 and 6 for the critical military power high-speed condition for an altitude of 40,000 feet were 0.63 and 0.64, respectively, as compared to 0.64 for the thickest section of the basic wing.

NACA RM L7E20

CORRELATION OF WIND-TUNNEL AND FLIGHT DETERMINATIONS OF THE BUFFET SPEED OF AN AIRPLANE EQUIPPED WITH EXTERNAL STORES. H. Norman Silvers and Kenneth P. Spreemann. March 2, 1948. 54p. diagrs., photos., tab. (NACA RM L7E20) (Declassified from Restricted, 9/16/52)

Presents a comparison of wind-tunnel measurements of incremental lift, drag, and pitching-moment coefficients due to external stores and measurements of pressures in the vicinity of the external stores with flight determinations of buffet Mach numbers. It is indicated that the variation of the incremental drag coefficient with Mach number of the external store may be used to estimate maximum flight buffet Mach number, and the attainment of local critical pressure in the vicinity of the store is indicative of the lower limit of flight buffet due to stores.

NACA RM L7K10

WIND-TUNNEL INVESTIGATION OF THE STABILITY OF JETTISONED NOSE SECTIONS OF THE D-558 AIRPLANE - PHASES I AND II. Stanley H. Scher. January 14, 1948. 33p. photos., diagrs., 6 tabs. (NACA RM L7K10) (Declassified from Confidential, 9/16/52)

An investigation of the stability of models of the jettisonable nose sections of the D-558 airplanes, Phases I and II, has been conducted in the Langley 20-foot free-spinning tunnel. It was found that both model nose sections tumbled end over end about an approximately horizontal axis. The installation of suitable fins, together with sufficient forward location of the center of gravity, prevented the tumbling and caused the models to descend in a stable nose-down attitude.

NACA RM L8E11

PRELIMINARY INVESTIGATION TO DETERMINE PROPELLER SECTION CHARACTERISTICS BY MEASURING THE PRESSURE DISTRIBUTION ON AN NACA 10-(3)(08)-03 PROPELLER UNDER OPERATING CONDITIONS. Albert J. Evans and George Liner. July 14, 1948. 52p. diagrs., tab. (NACA RM L8E11) (Declassified from Confidential, 9/16/52)

Contains preliminary data obtained by measuring the pressure distribution on the airfoil sections at nine

radial stations of an NACA 10-(3)(08)-03 design propeller. The results are presented as normal-force and moment coefficients for a range of nominal angle of attack (simple blade element theory) from 0° to 4° for a section Mach number range of about 0.6 to 1.15 for the outboard stations and about 0.3 to 0.6 for inboard stations.

NACA RM L8H11

AERODYNAMIC CHARACTERISTICS OF FLYING-BOAT HULLS HAVING LENGTH-BEAM RATIOS OF 20 AND 30. John M. Riebe. November 10, 1948. 26p. diagrs., photos., 4 tabs. (NACA RM L8H11) (Declassified from Restricted, 9/16/52)

An investigation of a series of hulls of length-beam ratios 6 to 15 previously reported in NACA TN 1305 has been extended to length-beam ratios 20 and 30. The hulls of the entire series were designed to have approximately the same hydrodynamic performance with respect to spray and resistance characteristics regardless of length-beam ratio. Drag coefficients and longitudinal-stability parameters are presented with and without wing interference. Lateral-stability parameters are presented with wing interference.

NACA RM L9G05

EFFECT OF AN INCREASE IN HULL LENGTH-BEAM RATIO FROM 15 TO 20 ON THE HYDRODYNAMIC CHARACTERISTICS OF FLYING BOATS. Arthur W. Carter and Walter E. Whitaker, Jr. August 24, 1949. 29p. diagrs., photos., 2 tabs. (NACA RM L9G05) (Declassified from Restricted, 9/16/52)

Investigations of the effect of hull lenth-beam ratio on the hydrodynamic qualities of flying boats, made in Langley tank No. 1, have been extended to include a length-beam ratio of 20. The hydrodynamic qualities determined in this investigation were longitudinal stability during take-off and landing, spray characteristics, and take-off performance in smooth water and take-off and landing behavior in waves.

AN INVESTIGATION OF THE TORSION CREEP-TO-RUPTURE PROPERTIES OF ALLOY N-155. M. E. Shank. (Final rept.) April 4, 1952. 34p. diagrs., photos. (Massachusetts Inst. of Tech., Research Lab. for Mechanics of Materials)

This report describes an investigation of the torsion creep-to-rupture properties of alloy N-155. All tests were in the range of 1200° to 1500° F, with times in the 10-1000 hour range. The effect of stress concentration in the form of transverse circular holes was investigated under similar conditions. The effect of specimen geometry, as affected by slight changes in specimen contours, was found to be great. Preliminary investigation was made into what appeared to be axial extension of the specimen during torsional creep.

APPLICATION OF TRANSONIC SIMILARITY CONSIDERATIONS TO FLOW ALONG A WAVE-SHAPED WALL. Carl Kaplan. 1952. 42p. diagrs., tab. (Presented at Eighth International Congress on Theoretical and Applied Mechanics held in Istanbul, Turkey, August 20-28, 1952).

The Prandtl-Busemann small-perturbation method is utilized to obtain the flow of a compressible fluid past an infinitely long wave-shaped wall. When the essential assumption for transonic flow (that all Mach numbers in the region of flow are nearly unity) is introduced, the expression for the velocity potential takes the form of a power series in the transonic similarity parameter. On the basis of this form of the solution, an attempt is made to solve the nonlinear differential equation for transonic flow past a wavy wall. The analysis utilized exhibits clearly the difficulties inherent in nonlinear-flow problems. Nevertheless, by means of the classical method of integration in series, recursion formulas for certain four-labelled coefficients are obtained. Remarkably enough, these recursion formulas can be solved analytically and lead to a number of conclusions; for example, that the transonic similarity parameter cannot be greater than four-thirds. In addition, a novel numerical test of convergence, applied to the power series (in the transonic similarity parameter) representing the local Mach number distribution at the boundary, indicates that smooth symmetrical potential flow past the wavy wall is no longer possible once the critical value of the undisturbed-stream Mach number has been exceeded.

CURRENT NACA REPORTS

NACA Rept. 1043

A NUMERICAL METHOD FOR THE STRESS ANALYSIS OF STIFFENED-SHELL STRUCTURES UNDER NONUNIFORM TEMPERATURE DISTRIBUTIONS. Richard R. Heldenfels. 1951. ii, 20p. diagrs., 9 tabs. (NACA Rept. 1043. Formerly TN 2241)

A numerical method is presented for the stress analysis of stiffened-shell structures of arbitrary cross section under nonuniform temperature distributions. The method is based on a previously published procedure that is extended to include temperature effects and multicell construction. The application of the method to practical problems is discussed and an illustrative analysis is presented of a two-cell box beam under the combined action of vertical loads and a nonuniform temperature distribution.

NACA Rept. 1044

THE METHOD OF CHARACTERISTICS FOR THE DETERMINATION OF SUPERSONIC FLOW OVER BODIES OF REVOLUTION AT SMALL ANGLES OF ATTACK. Antonio Ferri. 1951. ii, 16p. diagrs. (NACA Rept. 1044. Formerly TN 1809)

The method of characteristics has been applied to rotational supersonic flow around bodies of revolution at a small angle of attack. The practical numerical calculations are similar to those for zero angle of attack. A method for determining supersonic flow around circular cones at an angle of attack is also given.

NACA Rept. 1045

SUPERSONIC FLOW AROUND CIRCULAR CONES AT ANGLES OF ATTACK. Antonio Ferri. 1951. ii, 11p. diagrs. (NACA Rept. 1045. Formerly TN 2236)

The properties of conical flow without axial symmetry are analyzed. The flow around cones of circular cross section at small angles of attack is determined by correctly considering the effect of the entropy gradients in the flow.

NACA Rept. 1057

ANALYSIS OF THE EFFECTS OF BOUNDARY-LAYER CONTROL ON THE TAKE-OFF AND POWER-OFF LANDING PERFORMANCE CHARACTERISTICS OF A LIAISON TYPE OF AIRPLANE. Elmer A. Horton, Laurence K. Loftin, Jr., Stanley F. Racisz and John H. Quinn, Jr. 1951. ii, 31p. diagrs. (NACA Rept. 1057. Formerly TN 1597; TN 2143)

An investigation has been made to determine whether boundary-layer control by suction might reduce the minimum take-off and landing distance of a four-place or five-place airplane or a liaison type of airplane having a pay load of 1500 pounds and a flight duration of 5 hours. The aspect ratio was varied from 5 to 15, the wing span from 25 to 100 feet, and the brake horsepower from 300 to 1200. The effectiveness of boundary-layer control in reducing the total take-off distance for a given maximum speed improves with increasing aspect ratio and, for wing loadings of 10 pounds per square foot or more and an aspect ratio of 10 or more, the addition of boundary-layer control results in a decrease in the total take-off distance of as much as 14 percent. The use of boundary-layer control causes reduction in total landing distances (25 to 40 percent), ground-run distance, gliding speed, and stalling speed whereas sinking speed is increased only slightly.

NACA TN 2831

SPAN LOAD DISTRIBUTIONS RESULTING FROM CONSTANT ANGLE OF ATTACK, STEADY ROLLING VELOCITY, STEADY PITCHING VELOCITY, AND CONSTANT VERTICAL ACCELERATION FOR TAPERED SWEPTBACK WINGS WITH STREAMWISE TIPS. SUBSONIC LEADING EDGES AND SUPERSONIC TRAILING EDGES. Margery E. Hannah and Kenneth Margolis. December 1952. 221p. diagrs., 4 tabs. (NACA TN 2831)

On the basis of the linearized supersonic-flow theory the theoretical spanwise distributions of circulation (which are proportional to the span load distribution) resulting from constant angle of attack, steady rolling velocity, steady pitching velocity, and constant vertical acceleration were calculated for a series of thin, sweptback, tapered wings with streamwise tips, subsonic leading edges, and supersonic trailing edges. The results of the analysis are presented as a series of design charts. Some illustrative variations of the spanwise distributions of circulation with aspect ratio, taper ratio, Mach number, leading-edge sweepback, and axis-of-pitch location are also included.

NACA TN 2833

AN ANALYSIS OF NORMAL ACCELERATIONS AND AIRSPEEDS OF ONE TYPE OF TWIN-ENGINE TRANSPORT AIRPLANE IN COMMERCIAL OPERATIONS OVER A NORTHERN TRANSCONTINENTAL ROUTE. Roy Steiner. November 1952. 23p. diagrs., 4 tabs. (NACA TN 2833)

Normal-acceleration and airspeed data obtained for one type of twin-engine transport airplane in commercial operations over a northern transcontinental route are analyzed to determine the gust and gust-load experiences of the airplane. The acceleration increments experienced equaled or exceeded the limit-gust-load factor, on the average, twice (once positive and once negative) in about 7.5×10^6 flight miles, and an effective gust velocity of 30 feet per second was equaled or exceeded twice in about 1×10^6 flight miles. The data indicate that the maximum gusts and gust loads experienced in the winter were roughly 10 percent higher than those experienced in the summer on this route.

NACA TN 2837

CORRECTIONS FOR DRAG, LIFT, AND MOMENT OF AN AXIALLY SYMMETRICAL BODY PLACED IN A SUPERSONIC TUNNEL HAVING A TWO-DIMENSIONAL PRESSURE GRADIENT. I. J. Kolodner, F. Reiche and H. F. Ludloff, New York University. November 1952. 45p. (NACA TN 2837)

Corrections for drag, lift, and moment are derived for an axially symmetrical body placed in a supersonic tunnel having a two-dimensional pressure gradient. Although relatively simple longitudinal and transverse pressure gradients are assumed, the analytical treatment is rather difficult because of the difference in symmetry between the body and the basic flow field. Assuming irrotational conditions, the velocity potential of the flow around the body is expanded in powers of two parameters characterizing the body thickness and the inhomogeneity of the field and as a Fourier series in the azimuth around the body axis. Upon substitution of this potential series, the nonlinear equation of motion and the boundary condition on the body surface are split into a set of linearized boundary-value problems which can be solved analytically.

NACA TN 2840

BUCKLING OF LOW ARCHES OR CURVED BEAMS OF SMALL CURVATURE. Y. C. Fung and A. Kaplan, California Institute of Technology. November 1952. 75p. diagrs., photo., 9 tabs. (NACA TN 2840)

A general solution, based on the classical buckling criterion, is given for the problem of buckling of low arches under a lateral loading acting toward the center of curvature. For a sinusoidal arch under sinusoidal loading, the critical load can be expressed exactly as a simple function of the beam dimension parameters. For other arch shapes and load distributions, approximate values of the critical load can be obtained by summing a few terms of a rapidly converging Fourier series. The effects of initial end thrust and axial and lateral elastic support are discussed. The buckling load based on the energy criterion of Kármán and Tsien is also calculated. Results for both the classical and the energy criteria are compared with experimental results.

NACA TN 2841

INVESTIGATION OF 75-MILLIMETER-BORE DEEP-GROOVE BALL BEARINGS UNDER RADIAL LOAD AT HIGH SPEEDS. I - OIL-FLOW STUDIES. Zolton N. Nemeth, E. Fred Macks and William J. Anderson. December 1952. 30p. diagrs., 2 tabs. (NACA TN 2841)

At an oil inlet temperature of 100° F, two methods of bearing lubrication, single jet and puddling, were investigated. In this investigation, 75-millimeter-bore ball bearings were studied over a range of DN values (bore times speed) from 0.3×10^6 to 1.2×10^6, radial loads from 7 to 1113 pounds, and oil flows from 2 to 8 pounds per minute. The quantity of oil which flows through the bearing is shown to have an important effect on bearing operating temperatures and lubrication-system heat load. The effects of the operating variables on the oil flow through the bearing and upon the bearing outer- and inner-race temperatures are discussed.

NACA TN 2843

AUXILIARY EQUIPMENT AND TECHNIQUES FOR ADAPTING THE CONSTANT-TEMPERATURE HOT-WIRE ANEMOMETER TO SPECIFIC PROBLEMS IN AIR-FLOW MEASUREMENTS. James C. Laurence and L. Gene Landes. December 1952. ii, 77p. diagrs., photos., 3 tabs. (NACA TN 2843)

The constant-temperature hot-wire anemometer amplifier and accessories have been developed to provide an instrument with wide frequency response, good stability, and ease of operation. Auxiliary equipment has been developed to provide heating currents for large wires, to make average-square computations, and to make double-correlation coefficient measurements. Techniques are described for using this equipment to study periodic phenomena such as surge, rotating stall, and wake surveys in centrifugal- and axial-flow compressors. The application of the equipment to the study of nonperiodic phenomena such as intensity, scale, and spectra of isotropic turbulence is also discussed. Heat-loss data for standardized tungsten wire probes show that no wire calibration is necessary if accuracies of ± 5 percent are sufficient.

NACA TN 2844

LAMINAR BOUNDARY LAYER ON CONE IN SUPERSONIC FLOW AT LARGE ANGLE OF ATTACK. Franklin K. Moore. Appendix B: NUMERICAL SOLUTION OF DIFFERENTIAL EQUATIONS. Lynn Albers. November 1952. 34p. diagrs. (NACA TN 2844)

The laminar boundary-layer flow about a cone at large angles of attack to a supersonic stream has been analyzed in the plane of symmetry. At the bottom of the cone, velocity profiles were obtained showing the expected tendency of the boundary layer to become thinner on the under side of the cone as the angle of attack is increased. At the top of the cone, the analysis failed to yield unique solutions, except for small angle of attack. Beyond a certain critical angle of attack, boundary-layer flow does not exist in the plane of symmetry, thus indicating separation.

NACA RM L52K10a

PRELIMINARY RESULTS OF STABILITY CALCULATIONS FOR THE BENDING OF BOX BEAMS WITH LONGITUDINALLY STIFFENED COVERS CONNECTED BY POSTS. Roger A. Anderson, Thomas W. Wilder, III and Aldie E. Johnson, Jr. December 1952. 17p. diagrs., tab. (NACA RM L52K10a)

The preliminary results of a computational program are presented which give numerical values of the stiffnesses required of posts and longitudinal stiffeners along the row of posts to achieve desired buckling-stress values in the covers of a box beam subjected to bending. The validity of a short-cut solution to the stability equation derived in NACA TN 2760 is also shown.

NOTES ON THE PERFORMANCE OF CRYSTALLOY AND H. C. R. MAGNETIC MATERIALS IN TRANSDUCTOR CIRCUITS. A. G. Milnes and D. E. Fielder. May 1952. 22p. diagrs. (RAE Tech. Note EL. 35)

Transductor behavior with Crystalloy and H. C. R. as the core materials is examined and the sensitivity is shown to increase with increase in the supply voltage. As a result of this examination, a design flux density of 12,000 to 13,000 gauss (peak) is recommended for H. C. R. and 10,000 to 11,000 gauss (peak) for Crystalloy. The transductor characteristics obtained with H. C. R. cores are superior to those for Crystalloy; but to conserve supplies of nickel-iron materials, the use of Crystalloy or equivalent materials is advised for output stage transductors in applications where the highest standards of performance are not required.

THE "NATURAL VIGNETTING" OF PHOTOGRAPHIC LENSES. R. W. Fish. May 1952. 10p. diagrs. (RAE Tech. Note Ph. 466)

The variation of illumination in the focal plane of a photographic lens is commonly represented by the $\cos^4\theta$ law ("natural vignetting") in the absence of true vignetting, reflection and absorption losses, and veiling glare. It is shown that this $\cos^4\theta$ law only holds when the image is free from distortion and there is no aberration of the entrance pupil. The collimator method of measuring the variation of illumination is shown to be correct in theory. The application to wide angle lenses for air survey is briefly discussed.

A PHOTO-ELECTRIC CURVE FOLLOWER. R. H. Forrest and K. H. Treweek. With appendices. J. A. Roberts. May 1952. 61p. diagrs., photos. (RAE Tech. Note Arm. 487)

This curve follower reproduces in voltage form the ordinate of a curve recorded photographically as an opaque trace on clear film. A prototype instrument has been constructed and is described in some detail in the present paper. It is capable of following curves, recorded on 35-mm film, which do not exceed 80° in slope nor 20-mm peak to peak in amplitude at 60 cycles per second. The film is drawn past the face of a cathode ray tube in the X-axis direction and is viewed by a photocell which controls the Y-plate voltage to keep the luminous spot locked to the trace. The Y-plate voltage is therefore a measure of the curve ordinate. The follower works as a carrier frequency system and reads substantially the center of the recorded trace. The reading is therefore insensitive to line thickness and density,

and the reading error in the prototype is about 2 percent of full scale. The appendices describe the theory of the generation of the signals by the optical system and the use of a galvanometer in place of a cathode ray tube.

THE MEASUREMENT OF HEAT TRANSFER AND SKIN FRICTION AT SUPERSONIC SPEEDS. PART IV - TESTS ON A FLAT PLATE AT M = 2.82.
R. J. Monaghan and J. R. Cooke. June 1952. 43p. diagrs., 3 tabs. (RAE Tech. Note Aero 2171)

This note gives the results of over-all heat transfer and boundary-layer measurements made on a flat plate in a 5-in. square supersonic wind tunnel operating at M = 2.82 under atmospheric stagnation pressure conditions. The tests were made to extend the range of results previously obtained at M = 2.43[1, 2] and used the same experimental equipment. In general, the results confirm those obtained at the lower Mach number and some general conclusions are now drawn concerning the structure and behavior of experimental laminar and turbulent compressible boundary layers on a flat plate. The present series of tests is now complete, but subsonic check tests remain to be made.

ON THE STATICS OF THIN AIRCRAFT WINGS. (Zur Statik von dünnen Flugzeug-Tragflächen). H. Schürch. October 1952. 85p. diagrs., photo., 2 tabs. (Trans. from Eidgenössiche Technische Hochschule Zurich. Institut für Flugzeugstatik und Flugzeugbau. Mitteilungen 2, 1950, 62p.).

This paper deals with the structural analysis of flat structures, similar to those encountered in the wing and tail-plane design of modern aircraft. A sandwich type flat structure is considered. This structure is assumed to be built up of two faces, carrying normal and shearing loads and of a core of pure shearing rigidity normal to its center plane. The faces are assumed to be stiffened by an orthogonal system of stringers. Due to the stringers, the local bending rigidity of the flat structure is variable in different surface directions. An arbitrary variation of these bending rigidities is taken into account. Thus, the considered structure has essentially the properties of an orthotropic plate of variable thickness and differs from the usual aircraft wing design mainly by the assumption of a continuous and rigid system of ribs and webs, represented by the core. The relation between load and elastic deformation of such a flat structure is developed, starting from the theory of solid plates. Analysis yields a partial differential equation of fourth order with variable coefficients as an extension of the biharmonic equation for the deformation of solid plates of uniform thickness. By suppressing the rib bending, the said differential equation is linearized and a numerical computing becomes possible. Hence, a theory of a two dimensional flat structure can be developed, as an extension of the bending and twisting theory of the simple, one-dimensional beam.

CURRENT NACA REPORTS

NACA Rept. 1041

EQUATIONS AND CHARTS FOR THE RAPID ESTIMATION OF HINGE-MOMENT AND EFFECTIVENESS PARAMETERS FOR TRAILING-EDGE CONTROLS HAVING LEADING AND TRAILING EDGES SWEPT AHEAD OF THE MACH LINES. Kennith L. Goin. 1951. ii, 71p. diagrs., 9 tabs. (NACA Rept. 1041. Formerly TN 2221)

Existing conical-flow solutions have been used to calculate the characteristics of deflected trailing-edge controls located either at the wing tip or far enough inboard to prevent the outermost Mach lines from the controls from crossing the wing tip. For either location, the controls have been assumed to be located far enough outboard to prevent the innermost Mach lines from crossing the wing-root chord. The method for determining control hinge moment resulting from wing angle-of-attack loading is restricted to wings having leading edges swept ahead of the Mach lines. Also included is an approximate method by which the theoretical characteristics may be corrected for airfoil-section thickness.

NACA Rept. 1058

INFLUENCE OF CHEMICAL COMPOSITION ON RUPTURE PROPERTIES AT 1200° F OF FORGED CHROMIUM-COBALT-NICKEL-IRON BASE ALLOYS IN SOLUTION-TREATED AND AGED CONDITION. E. E. Reynolds, J. W. Freeman and A. E. White, University of Michigan. 1951. ii, 60p. diagrs., photos., 11 tabs. (NACA Rept. 1058. Formerly TN 2449)

Use of careful control over processing conditions in this investigation has shown that it is possible to correlate stress-rupture properties of forged chromium-cobalt-nickel-iron base alloys at 1200° F with systematic variations in chemical composition and that a wide range in properties can be obtained by such variations. However, no alloy was obtained which had properties which were outstanding compared with those of the basic analysis.

NACA TN 2822

A SPECIAL INVESTIGATION TO DEVELOP A GENERAL METHOD FOR THREE-DIMENSIONAL PHOTOELASTIC STRESS ANALYSIS. M. M. Frocht and R. Guernsey, Jr., Illinois Institute of Technology. December 1952. 59p. diagrs., photos., 3 tabs. (NACA TN 2822)

The method of strain measurement after annealing is reviewed and found to be unsatisfactory for the materials available in this country. A new, general method is described for the photoelastic determination of the principal stresses at any point of a general body subjected to arbitrary loads. The method has been applied to a sphere subjected to diametral compressive loads. The results show possibilities of high accuracy.

NACA TN 2832

THEORETICAL STUDY OF THE TRANSONIC LIFT OF A DOUBLE-WEDGE PROFILE WITH DETACHED BOW WAVE. Walter G. Vincenti and Cleo B. Wagoner. (Portions of this work were reported at the eighth International Congress on Theoretical and Applied Mechanics, Istanbul, Turkey, August 20-28, 1952). December 1952. 63p. diagrs., 2 tabs. (NACA TN 2832)

Numerical calculations are described of the aerodynamic characteristics at small angle of attack of a thin, doubly symmetrical, double-wedge profile in the range of supersonic flight speed in which the bow wave is detached. The analysis is carried out within the framework of the transonic (nonlinear) small-disturbance theory. The following results are provided as functions of the transonic similarity parameter: (1) chordwise lift distribution, (2) lift-curve slope, and (3) position of center of lift.

NACA TN 2836

RADIANT-INTERCHANGE CONFIGURATION FACTORS. D. C. Hamilton and W. R. Morgan, Purdue University. December 1952. 110p. diagrs., photos., 14 tabs. (NACA TN 2836)

A study is presented of the geometric configuration factors required for computing radiant heat transfer between opaque surfaces separated by a nonabsorbing medium and various methods of determining the configuration factors are discussed. Configuration-factor solutions available in the literature have been checked and the more complicated equations are presented as families of curves. Cases for point, line, and finite-area sources are worked out over a wide range of geometric proportions. These cases include several new configuration involving rectangles, triangles, and cylinders of finite length which are integrated and tabulated. An analysis is presented, in which configuration factors are employed, of the radiant heat transfer to the rotor blades of a typical gas turbine under different conditions of temperature and pressure.

NACA TN 2838

CALORIMETRIC DETERMINATION OF CONSTANT-PRESSURE SPECIFIC HEATS OF CARBON DIOXIDE AT ELEVATED PRESSURES AND TEMPERATURES. Virgil E. Schrock, University of California. December 1952. 46p. diagrs., 2 tabs. (NACA TN 2838)

The constant-pressure specific heat of carbon dioxide has been measured over the range of temperatures and pressures from ambient conditions to 1000 pounds per square inch gage and 1000° F using a steady-flow calorimeter operated on an open cycle. It appears that the apparatus as used in this determination will yield values with a probable error of 0.5 percent at the highest temperature level considered. The results of these tests check the widely accepted spectroscopic data within 1 percent. The values at elevated pressure are in reasonable agreement with those derived from the zero-pressure spectroscopic values and the application of the Beattie-Bridgeman equation of state. Only very limited calorimetric data are available in the literature, but substantial agreement exists with those considered reliable.

NACA TN 2842

THE PLANING CHARACTERISTICS OF A SURFACE HAVING A BASIC ANGLE OF DEAD RISE OF 40° AND HORIZONTAL CHINE FLARE. Ulysse J. Blanchard. December 1952. 26p. diagrs., photo., tab. (NACA TN 2842)

The principal planing characteristics of a surface having an angle of dead rise of 40° and horizontal chine flare are presented. The data indicate that at a given trim the important planing characteristics depend mainly on lift coefficient. The effects of increasing the basic angle of dead rise from 20° (NACA TN 2804) to 40° are to decrease the ratio of the center-of-pressure location to the mean wetted length, to decrease the extent of pile-up of water at the keel, and to increase the friction drag.

NACA TN 2846

EFFECTIVE LUBRICATION RANGE FOR STEEL SURFACES BOUNDARY LUBRICATED AT HIGH SLIDING VELOCITIES BY VARIOUS CLASSES OF SYNTHETIC FLUIDS. Robert L. Johnson, Max A. Swikert and Edmond E. Bisson. December 1952. 23p. diagrs., photos., tab. (NACA TN 2846)

Synthetic lubricants are necessary in order to satisfy the physical-property requirements for future lubricants of aircraft turbine engines. Since boundary-lubrication data on synthetic fluids are limited, the effects of a wide range of sliding velocities on boundary lubrication were studied. Friction data and surface-failure properties showed that a silicone diester blend, an alkyl silicate ester, and a compounded diester (containing lubrication additives) were more effective lubricants at high sliding velocities than the comparable diesters from which the most widely accepted synthetic lubricants are made. The diesters as well as polyethers, silicate ester, and phosphonate esters are more effective boundary lubricants at high sliding velocities than petroleum oils of comparable viscosity. In a preliminary study of the mechanism of lubrication by diesters, it was found that a diester failed to lubricate nonreactive surfaces, possibly indicating that the mechanism may involve chemical reaction of the diesters with the lubricated surfaces.

NACA TN 2847

SECTION CHARACTERISTICS OF A 10.5-PERCENT-THICK AIRFOIL WITH AREA SUCTION AS AFFECTED BY CHORDWISE DISTRIBUTION OF PERMEABILITY. Robert E. Dannenberg and James A. Weiberg. December 1952. 52p. diagrs., photos., 3 tabs. (NACA TN 2847)

Results are presented of an investigation of a two-dimensional, 10.51-percent-thick symmetrical airfoil with area suction near the leading edge. Area suction delayed leading-edge stall. Maximum lift appeared to be limited by turbulent separation from the trailing edge. The suction flow and power coefficients required to maintain a given lift are shown to be dependent on the chordwise extent and the porosity and permeability arrangement of the surface material. The flow-resistance characteristics of several porous materials are presented.

NACA TN 2848

INVESTIGATION OF SPONTANEOUS IGNITION TEMPERATURES OF ORGANIC COMPOUNDS WITH PARTICULAR EMPHASIS ON LUBRICANTS. Charles E. Frank, Angus U. Blackham and Donald E. Swarts, University of Cincinnati. December 1952. 40p. diagrs., 6 tabs. (NACA TN 2848)

The study of spontaneous ignition characteristics of organic compounds has been extended to include various types of lubricants by using a spray-injection as well as a dropwise-addition procedure. It has been shown that certain nonvolatile compounds previously considered to have relatively high spontaneous ignition temperatures exhibit basically the same ease of ignition as the lower-molecular-weight, more-volatile compounds. Of the lubricants studies, the polyisobutylenes were the only ones which gave consistently high spontaneous ignition temperatures (about 400° C) in all molecular-weight ranges. The influence of additives and metal surfaces on spontaneous ignition temperatures and on the ignition behavior of selected two-component mixtures was also determined.

NACA TN 2849

CORRECTIONS FOR LIFT, DRAG, AND MOMENT OF AN AIRFOIL IN A SUPERSONIC TUNNEL HAVING A GIVEN STATIC PRESSURE GRADIENT. H. F. Ludloff and M. B. Friedman, New York University. December 1952. 69p. diagrs. (NACA TN 2849)

Corrections for lift, drag and moment of a two-dimensional airfoil are analyzed assuming that the airfoil is tested in a supersonic tunnel in which the pressure field, instead of being uniform, is characterized by gradients in the axial and transverse directions. The tunnel gradients as well as the airfoil effect are regarded as perturbations of the original rectilinear flow field of given Mach number. Therefore the velocity potential of the flow, the nonlinear differential equation of motion, and the boundary conditions are expanded into double series in powers of two parameters characterizing the airfoil thickness and the inhomogeneity of the field. The nonlinear problem is thus split into a system of linear boundary-value problems which can be solved analytically. The resulting expressions have been derived for arbitrary given pressure gradients and general profile form.

NACA TN 2851

THE AERODYNAMIC DESIGN OF SUPERSONIC PROPELLERS FROM STRUCTURAL CONSIDERATION. Jerome B. Hammack. December 1952. 21p. diagrs. (NACA TN 2851)

A solution for radial distribution of cross-sectional area of supersonic propellers so that blade sections operate at maximum allowable centrifugal stress is given. The aerodynamic characteristics of some propellers designed by this method for Mach numbers from 0.9 to 2.4 for advance ratios of 2.0 and 3.0 are discussed.

NACA TN 2852

AN INVESTIGATION UTILIZING AN ELECTRICAL ANALOGUE OF CYCLIC DE-ICING OF A HOLLOW STEEL PROPELLER WITH AN EXTERNAL BLADE SHOE. Carr B. Neel, Jr. December 1952. 54p. diagrs., photos., 3 tabs. (NACA TN 2852)

A study of the heat requirements for cyclic de-icing of hollow steel propellers fitted with external blade shoes, utilizing an electrical analogue, showed how energy requirements could be decreased by changes in the method of operation of existing shoes and through proper blade-shoe design. Savings in total energy in the order of 60 percent would be possible in each case. Energy requirements were shown to increase with decreasing liquid-water content and air temperature.

NACA TN 2855

GENERAL CORRELATION OF TEMPERATURE PROFILES DOWNSTREAM OF A HEATED AIR JET DIRECTED AT VARIOUS ANGLES TO AIR STREAM. Robert S. Ruggeri. December 1952. 59p. diagrs., tab. (NACA TN 2855)

An experimental investigation was conducted to determine the temperature profile downstream of a heated-air jet directed at various angles to an air stream. The profiles were determined at two positions downstream of the jet as a function of jet diameter, jet density, free-stream density, jet velocity, free-stream velocity, jet total temperature, orifice flow coefficient, and jet discharge angles. A method is presented which yields a good approximation of the temperature profile in terms of dimensionless parameters of the flow and geometric conditions.

NACA TN 2857

A THEORETICAL METHOD OF ANALYZING THE EFFECTS OF YAW-DAMPER DYNAMICS ON THE STABILITY OF AN AIRCRAFT EQUIPPED WITH A SECOND-ORDER YAW DAMPER. Albert A. Schy and Ordway B. Gates, Jr. December 1952. 72p. diagrs., 2 tabs. (NACA TN 2857)

A method is presented for analyzing the effects of autopilot gain, natural frequency, and damping ratio on the damping of an aircraft equipped with a second-order autopilot. The method is illustrated by analyzing the effects of a second-order yaw damper on the lateral motion of an airplane. Constant-damping curves which show the effect of varying autopilot parameters on system damping are plotted and discussed. Greater damping is shown to be obtainable from a second-order yaw damper than from a no-lag yaw damper with the same gain. A method of designing yaw dampers is discussed.

NACA TN 2858

SUPERSONIC WAVE DRAG OF NONLIFTING DELTA WINGS WITH LINEARLY VARYING THICKNESS RATIO. Arthur Henderson, Jr. December 1952. 51p. diagrs. (NACA TN 2858)

The supersonic wave drag of a nonlifting, symmetrical, double-wedge-profile, delta wing the thickness ratio of which varies linearly in the spanwise direction is calculated by means of linear theory. In general it is found that a delta wing with linearly varying thickness ratio can have less wave drag than a constant thickness-ratio delta wing of the same plan form when both wings have either the same projected frontal area or the same internal volume. The thickness distributions for minimum drag and the corresponding values of the ratio of the drag of a linearly varying thickness-ratio wing to a constant-thickness-ratio wing are found.

NACA TN 2859

THE LANGLEY 2,000-HORSEPOWER PROPELLER DYNAMOMETER AND TESTS AT HIGH SPEED OF AN NACA 10-(3)(08)-03 TWO-BLADE PROPELLER. Blake W. Corson, Jr. and Julian D. Maynard. December 1952. 75p. diagrs., photos., 3 tabs. (NACA TN 2859. Formerly RM L7L29)

This paper contains a detailed description of a 2,000-horsepower propeller dynamometer used to make wind-tunnel tests of a two-blade NACA 10-(3)(08)-03 propeller for a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour. The results of these tests and comparisons with results obtained from a theoretical analysis and from previous tests made in other wind tunnels are presented.

NACA TN 2860

INTERACTION BETWEEN A SUPERSONIC STREAM AND A PARALLEL SUBSONIC STREAM BOUNDED BY FLUID AT REST. Herbert S. Ribner and E. Leonard Arnoff. December 1952. 45p. diagrs., 2 tabs. (NACA TN 2860)

Tsien and Finston's simplified model of shock boundary-layer interaction is modified to introduce effects of the separated "dead-air" bubble, where one exists. The boundary layer is simulated by an inviscid uniform subsonic stream bounded below by fluid at rest and impinged on above by a weak oblique shock in an infinite supersonic stream. Linearized analysis indicates that the simulated boundary layer approximates the expansive corner turn that would occur if the shock were incident directly on the dead-air region; there are localized distortions top and bottom.

NACA TN 2862

INFLUENCE OF NONMARTENSITIC TRANSFORMATION PRODUCTS ON MECHANICAL PROPERTIES OF TEMPERED MARTENSITE. J. M. Hodge and W. T. Lankford, United States Steel Company. December 1952. 13p. diagrs., 4 tabs. (NACA TN 2862)

The influence of nonmartensitic transformation products on the mechanical properties of tempered martensite is presented for samples of an SAE 4340 steel, partially isothermally transformed to specific high-temperature transformation products and quenched and tempered to hardness values of from 25 to 40 Rockwell C. The effects of upper bainite in amounts of 1, 5, 10, 20, and 50 percent, of 5 percent ferrite, and of 5 percent pearlite on the tensile, impact, and fatigue properties are evaluated.

NACA TN 2863

LAMINAR NATURAL-CONVECTION FLOW AND HEAT TRANSFER OF FLUIDS WITH AND WITHOUT HEAT SOURCES IN CHANNELS WITH CONSTANT WALL TEMPERATURES. Simon Ostrach. December 1952. 55p. diagrs. (NACA TN 2863)

An analysis of the natural-convection phenomenon shows that the flow and heat transfer, in general, not only are functions of the Prandtl and Grashof numbers but also depend on a new dimensionless parameter. If this parameter is not negligibly small, the compression work and frictional heating may appreciably affect this mode of heat transfer. Particular consideration is given to the fully developed natural-convection flow of fluids with and without heat sources between two long parallel plane surfaces whose temperatures are maintained constant but not necessarily equal. Detailed velocity and temperature distributions are obtained from which the effects of heat sources in the fluids and frictional heating on the process can be seen. Frictional heating and heat sources increase the velocities and temperatures. Increasing the ratio of the two wall-temperature differences (wall minus outside ambient) also leads to similar results.

NACA RM E52I22

VARIATION IN SMOKING TENDENCY AMONG LOW MOLECULAR WEIGHT HYDROCARBONS. Rose L. Schalla and Glen E. McDonald. December 1952. 16p. diagrs., 3 tabs. (NACA RM E52I22)

An investigation was made of the variations in smoking tendency among 38 gaseous and liquid pure hydrocarbon compounds when burned as diffusion flames in still air. The maximum rates at which the fuels could be burned smoke-free varied as follows: n-paraffins > isoparaffins > monoolefins > alkynes > aromatics. Cyclic paraffins and olefins as well as diolefins were also studied. Their position overlapped the trends of several of the series presented. Variations in smoking tendencies within the given homologous series were rather complex, but a tentative explanation is that the greater the strength of the carbon bonds or skeleton of the hydrocarbon molecule, the greater will be its tendency to form smoke during combustion. From this suggested explanation a possible mechanism based on dehydrogenation and subsequent polymerization of the carbon nuclei was proposed as the initial step involved in the formation of smoke.

NACA RM E52J06

PRELIMINARY SURVEY OF ICING CONDITIONS MEASURED DURING ROUTINE TRANSCONTINENTAL AIRLINE OPERATION. Porter J. Perkins. December 1952. 27p. diagrs., photos., 3 tabs. (NACA RM E52J06)

Icing data collected on routine operations by four DC-4-type transport aircraft equipped with NACA pressure-type icing-rate meters and flying over a transcontinental route from January through May 1951 are presented. The four aircraft were in icing conditions approximately 1-1/2 percent of the total flying time. Nearly one-half of the icing conditions were encountered over the Great Lakes area. Average liquid-water-content measurements did not exceed 1.0 gram per cubic meter and 80 percent of the measurements did not exceed 0.4 gram per cubic meter. The data are considered only preliminary and the program is continuing to provide additional data from world-wide air routes.

CURRENT NACA REPORTS

NACA Rept. 1082

METHOD OF ANALYSIS FOR COMPRESSIBLE FLOW THROUGH MIXED-FLOW CENTRIFUGAL IMPELLERS OF ARBITRARY DESIGN. Joseph T. Hamrick, Ambrose Ginsburg and Walter M. Osborn. 1952. ii, 10p. diagrs. (NACA Rept. 1082. Formerly NACA TN 2165)

A method is presented for the analysis of compressible flow between the hub and the shroud of mixed-flow impellers of arbitrary design. Axial symmetry was assumed, but the forces in the meridional (hub-shroud) plane, which are derived from tangential pressure gradients, were taken into account. The method was applied to an experimental mixed-flow impeller. The analysis of the flow in the meridional plane of the impeller showed that the rotational forces, the blade curvature, and the hub-shroud profile can introduce severe velocity gradients along the hub and shroud surfaces. Choked flow at the impeller inlet as determined by the analysis was verified by experimental results.

NACA TN 2845

X-RAY INSTRUMENTATION FOR DENSITY MEASUREMENTS IN A SUPERSONIC FLOW FIELD. John Dimeff, Ralph K. Hallett, Jr. and C. Frederick Hansen. December 1952. 39p. diagrs., photos., 2 tabs. (NACA TN 2845)

An instrument has been constructed to measure the density of an air stream by utilizing the reduction in intensity of an undeviated beam of X rays. This equipment has been designed for density ranges from 2×10^{-5} to 3×10^{-4} grams per cubic centimeter. Path-length-density products were measured within 5×10^{-5} g/cm^2 for X-ray-beam areas of 5×10^{-4} cm^2 and averaging times of 30 seconds, and within 1×10^{-5} g/cm^2 for beam areas of 8×10^{-3} cm^2 and averaging times of 5 minutes.

NACA TN 2850

STUDY OF PRESSURE EFFECTS ON VAPORIZATION RATE OF DROPS IN GAS STREAMS. Robert D. Ingebo. January 1953. 36p. diagrs., 5 tabs. (NACA TN 2850)

Vaporization-rate and surface-temperature data were obtained for four pure liquids evaporating from the surface of a porous sphere in air streams having a static pressure range of 450 to 1500 millimeters of mercury. Data were also obtained for methanol evaporating in streams of helium, argon, and carbon dioxide. Experimental heat-transfer coefficients were found to correlate a semiempirical equation which shows the Nusselt number to be a function of the group ReSc, the thermal-conductivity ratio, and the molecular-scale momentum-transfer ratio of gravitational to inertial forces. These data show the heat-transfer coefficient to be independent of the static pressure of the gas stream, and the effect of pressure on the vaporization rate to be determined directly by the effect of pressure on the surface temperature of the drop. An equation is also presented for calculating the driving potential Δt value for water at a static pressure of 450 to 1500 millimeters of mercury by using the Δt^* value for 1 atmosphere pressure and a calculated correction term $\Delta t'$.

NACA TN 2853

A STUDY OF THE APPLICATION OF POWER-SPECTRAL METHODS OF GENERALIZED HARMONIC ANALYSIS TO GUST LOADS ON AIRPLANES. Harry Press and Bernard Mazelsky. January 1953. 48p. diagrs., 2 tabs. (NACA TN 2853)

The applicability of some results from the theory of generalized harmonic analysis to the analysis of gust loads on airplanes in continuous rough air is examined. The input and output relations in terms of power spectrums are used to relate the standard deviation (root mean square) of loads in continuous rough air to the gust response characteristics of the airplane and the spectral characteristics of atmospheric turbulence. For the case of a normally distributed output, which appears from experimental evidence to apply to a homogeneous turbulence condition, the probability distribution of loads is shown to be a simple function of the output power spectrum. In order to illustrate the application of power-spectral analysis to gust loads and to obtain an insight into the relation between loads in continuous rough air and the gust response characteristics of the airplane, two selected series of calculations are presented. The results of these applications are compared with those obtained from calculations for single gusts and their implications are discussed.

NACA TN 2854

AVERAGE SKIN-FRICTION DRAG COEFFICIENTS FROM TANK TESTS OF A PARABOLIC BODY OF REVOLUTION (NACA RM-10). Elmo J. Mottard and J. Dan Loposer. January 1953. 18p. diagrs., photos. (NACA TN 2854)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

Average skin-friction drag coefficients were obtained from boundary-layer total-pressure measurements on a parabolic body of revolution (NACA RM-10) basic fineness ratio 15) in water at Reynolds numbers from 4.4×10^6 to 70×10^6. The tests were made in the Langley tank no. 1 with the body sting-mounted at a depth of two maximum body diameters. The arithmetic mean of three drag measurements taken around the body was in good agreement with flat-plate results, but, apparently because of the slight surface wave caused by the body, the distribution of the boundary layer around the body was not uniform over part of the Reynolds number range.

NACA TN 2861

ANALYTICAL INVESTIGATION OF ICING LIMIT FOR DIAMOND-SHAPED AIRFOIL IN TRANSONIC AND SUPERSONIC FLOW. Edmund E. Callaghan and John S. Serafini. January 1953. 18p. diagrs. (NACA TN 2861)

Calculations have been made for the icing limit of a diamond airfoil at zero angle of attack in terms of the stream Mach number, stream temperature, and pressure altitude. The icing limit is defined as a wetted-surface temperature of 32° F and is related to the stream conditions by the method of Hardy. The results show that the point most likely to ice on the airfoil lies immediately behind the shoulder and is subject to possible icing at Mach numbers as high as 1.4.

NACA TN 2866

ICING PROTECTION FOR A TURBOJET TRANSPORT AIRPLANE: HEATING REQUIREMENTS, METHODS OF PROTECTION, AND PERFORMANCE PENALTIES. Thomas F. Gelder, James P. Lewis and Stanley L. Koutz. January 1953. i, 57p. diagrs., tab. (NACA TN 2866)

The heating requirements for several methods of icing protection for a typical turbojet transport airplane operating over a probable range of icing conditions are evaluated, and the airplane performance penalties associated with providing this protection from various energy sources are assessed. Continuous heating requirements and airplane penalties for the turbojet transport are considerably increased over those for lower-speed aircraft. Heating requirements can be substantially reduced by use of a cyclic de-icing system and choice of the proper energy source.

NACA RM E52J13

PREDICTION OF FLAME VELOCITIES OF HYDROCARBON FLAMES. Gordon L. Dugger and Dorothy M. Simon. January 1953. 23p. diagrs., 3 tabs. (NACA RM E52J13)

The effects of four combustible-mixture variables on the laminar flame velocities of hydrocarbon-oxygen-nitrogen mixtures are predicted by semitheoretical methods based on (1) Semenov equation (thermal mechanism), (2) Tanford-Pease equation (active-particle-diffusion mechanism), and (3) Manson equation (momentum-pressure-drop equation using active-particle concentrations). A semiempirical factor, calculated from flame velocity data, is required by each of these equations. When these factors are calculated for each variable separately, mean deviations between calculated and measured flame velocities are 2 to 15 percent for the variables studied, namely, hydrocarbon structure, equivalence ratio, oxygen-nitrogen ratio, and initial temperature. When the semiempirical factor for one variable is used to predict the effect of another variable, the mean deviations are approximately doubled. Empirical equations are summarized which give better predictions, but require more constants.

NACA RM E52J24

FLAME VELOCITIES OF PROPANE- AND ETHYLENE-OXYGEN-NITROGEN MIXTURES. Gordon L. Dugger and Dorothy D. Graab. January 1953. 23p. diagrs., 3 tabs. (NACA RM E52J24)

Laminar flame velocities of propane and ethylene with oxygen-nitrogen mixtures containing 0.166 to 0.496 mole fraction of oxygen were determined as a function of mixture composition at 311° and 422° K by a Bunsen-burner method. For each case flame velocity increased linearly with oxygen concentration. Empirical equations including the effects of initial temperature and oxygen concentration were obtained. Thermal and diffusion theories were used to predict the relative effect of oxygen concentration on maximum flame velocity within 5 to 15 percent. No linear correlations between maximum flame velocity and calculated active particle concentrations were obtained.

NACA RM E52J28

SPARK IGNITION OF FLOWING GASES. III - EFFECT OF TURBULENCE PROMOTER ON ENERGY REQUIRED TO IGNITE A PROPANE-AIR MIXTURE. Clyde C. Swett, Jr. and Richard H. Donlon. January 1953. 7p. diagrs. (NACA RM E52J28)

An investigation was conducted to determine the effect of turbulence generated by different sizes of wire grid on the minimum spark-ignition energy of a flowing propane-air mixture. Test conditions were: pressure, 5 inches of mercury absolute; temperature, 80° F; fuel-air ratio, 0.0835 (by weight); velocity, 50 to 250 feet per second; spark duration, 500 microseconds; and electrode spacing, 0.37 inch. The wire sizes of the turbulence promoters ranged from 0.006 to 0.105 inch in diameter and the promoters were located either 4-3/8 or 6-3/8 inches upstream of the spark electrodes. The investigation was conducted with turbulence having superimposed flow pulsations and duct resonance. The required ignition energy increased with wire size of the turbulence promoter and with gas velocity and decreased with distance from the promoter to the spark electrodes. The required ignition energy therefore in-

creased with those factors that are reported to generate increased intensity of turbulence. At a velocity of 250 feet per second, three times more energy was required with the 0.105-inch wire-diameter promoter than with no promoter.

NACA TM 1324

STEADY VIBRATIONS OF WING OF CIRCULAR PLAN FORM. (Ob ustanovivshikhsya kolebaniyakh kryla krugovoi formy v plane). THEORY OF WING OF CIRCULAR PLAN FORM. (Teoriya kryla konechnogo razmakha krugovoi formy v plane). N. E. Kochin. January 1953. 93p. diagrs. (NACA TM 1324. Trans. from: Prikladnaya Matematika i Mekhanika, v. 6, no. 4, 1942, p. 287-316; Prikladnaya Matematika i Mekhanika, v. 4, no. 1, 1940, p. 3-32).

This paper treats the problem of determining the lift, moment, and induced drag of a thin wing of circular plan form in uniform incompressible flow on the basis of linearized theory. As contrasted to a similar paper by Kinner, in which the acceleration potential method was used, the present paper utilizes the concept of the velocity potential. Calculations of the lift and moment are presented for several deformed shapes. It is shown that considerable deviations exist between the strip theory analysis and the more exact theory. The lift, moment, and induced drag are also determined for a harmonically oscillatory circular plan form wing. As constrasted to a similar paper by Schade, in which the acceleration potential method was used, the present paper utilizes the concept of the velocity potential. Expressions for lift, moment, and induced drag are given and finally specialized to the case of a slowly oscillating circular wing.

National Gas Turbine Establishment (Gt. Brit.)
A DIRECT, EASILY COMPUTABLE METHOD FOR THE EVALUATION OF CENTRIFUGAL AND THERMAL STRESSES IN DISCS, AND STRESS CHANGES DUE TO PLASTIC FLOW AND CREEP. R. L. Brooking, J. Brown and B. R. Atkins. July 1952. 68p. diagrs., 7 tabs. (NGTE R. 122)

A method is presented below by the use of which stressing of turbine disks may be performed. It permits the evaluation of stresses due both to rotation, and to existence of a thermal gradient radially across the disk. The method is extended to cover the calculation of the stress changes which occur at any point under conditions where stresses exceed the elastic limit of the disk material (plastic flow), or where the disk is rotating for long periods of time under given conditions (creep). The method is a direct one in that it involves neither initial stress assumptions nor successive approximations. It may be described as a small-difference, step-by-step method, and can be set out in an easily computable form, the operation of which requires little mathematical knowledge. Two examples of the application of the method are given. One treats an aeroengine turbine disk in which the stress changes due to plastic flow are included, and the results obtained by this are compared with those obtained using a somewhat more mathematical method due to Prof. Hartree. Good agreement is exhibited. The second example shows the evaluation of the stress distribution in a rotor after 10,000 hours under steady running conditions, the latter example showing also the application to this problem of a current theory on creep data.

Aeronautical Research Council (Gt. Brit.) OBSERVATIONS ON A THIN CAMBERED AEROFOIL BEYOND THE CRITICAL MACH NUMBER. E. W. E. Rogers. July 7, 1950. 23p. diagrs., photos. (ARC 13,238; Perf. 685; FM 1455)

In the course of surface pressure measurements and wake traverses on an airfoil section of 10-percent thickness-chord ratio, tested at high subsonic speeds in the 20 in. x 8 in. (50.8 cm x 20.3 cm) high speed tunnel of the National Physical Laboratory, it was discovered that at a particular incidence (3.7°) an extensive region of supersonic velocity ($M = 1.15$) existed without the formation of a well-defined shock wave or a rise of drag. The drag coefficient in fact decreased markedly as the Mach number was raised from a low value, and this was accompanied by a rearward movement on the upper surface of the position of boundary layer transition corresponding to a favorable change of the surface pressure gradient. In an attempt to explain this phenomenon, some analysis is made of the observed pressure distribution curves, and the measured transition positions are compared with those estimated from the observed drag coefficients. Direct shadow photographs illustrate the development of the shockwave pattern.

N-20260*

Aeronautical Research Council (Gt. Brit.) A NOTE ON THE BOUNDARY LAYER AND STALLING CHARACTERISTICS OF AEROFOILS. D. D. Carrow. October 5, 1950. 21p. diagrs. (ARC 13,424; Perf. 697; S & C 2435)

A qualitative explanation is suggested for the changes which occur in the stalling characteristics of airfoils as the Reynolds number is increased. This explanation is based on the variation, with Reynolds number, in the state of the boundary layer along the upper surface at just below the stalling incidence.

Errata No. 1 on "EQUATIONS AND CHARTS FOR THE RAPID ESTIMATION OF HINGE-MOMENT AND EFFECTIVENESS PARAMETERS FOR TRAILING-EDGE CONTROLS HAVING LEADING AND TRAILING EDGES SWEPT AHEAD OF THE MACH LINES". Kennith L. Goin. 1951.

UNPUBLISHED PAPERS

N-12887*

TURBULENT HETEROGENEOUS COMBUSTION. (Turbulentnoe geterogennoe gorenie). S. A. Goldenberg. 16p. diagrs. (Trans. from Izvestia Akademii Nauk SSSR, no. 8, August 1950, p. 1154-1164).

An experimental investigation was made of the process of combustion of carbon in the form of a cylindrical tube for turbulent flow of the gases with velocities from 22 to 145 meters per second. On the basis of the hydrodynamic characteristics determining the transport of the masses in the turbulent flow (the coefficient of turbulent diffusion), an approximate analytical method is given for the computation of the combustion process. The temperature dependence was obtained for the coefficient of gas exchange within the temperature range 500° to 1050°, which is expressed by the formula $\alpha \approx 8.5 \times 10^{5} \exp(-18,000/RT)$.

NOTICE

Due to space limitations the NACA's stock of Wartime Reports is being dispersed. If you wish copies of Wartime Reports for your files, it is requested you make your needs known prior to March 1, 1953. Your letter should list by Wartime Report numbers the items desired. Distribution will be on a first come first served basis. Wartime Reports will be on a "loan only" basis after March 1, 1953.

CURRENT NACA REPORTS

NACA Rept. 1070

MATRIX METHOD OF DETERMINING THE LONGITUDINAL-STABILITY COEFFICIENTS AND FREQUENCY RESPONSE OF AN AIRCRAFT FROM TRANSIENT FLIGHT DATA. James J. Donegan and Henry A. Pearson. 1952. ii, 11p. diagrs., 3 tabs. (NACA Rept. 1070. Formerly TN 2370)

A method is presented for obtaining the over-all longitudinal-stability coefficients and frequency response of an aircraft from an analysis of arbitrary maneuvers in which simple instrumentation is used. Although the method presented deals entirely with the aircraft, it is equally applicable to other problems which can be expressed by second-order differential equations.

NACA TN 2839

DEVELOPMENT OF TURBULENCE-MEASURING EQUIPMENT. Leslie S. G. Kovásznay. National Bureau of Standards. January 1953. 86p. diagrs., photos. (NACA TN 2839)

Hot-wire turbulence-measuring equipment has been developed to meet the more-stringent requirments involved in the measurement of fluctuations in flow parameters at supersonic velocities. The higher mean speed necessitates the resolution of higher frequency components than at low speed, and the relatively low turbulence level present at supersonic speed makes necessary an improved noise level for the equipment. The equipment covers the frequency range from 2 to 70,000 cycles per second. The equipment is adaptable to all-purpose turbulence work with improved utility and accuracy over that of older types of equipment. Sample measurements are given to demonstrate the performance.

NACA TN 2856

ESTIMATED POWER REDUCTION BY WATER INJECTION IN A NONRETURN SUPERSONIC WIND TUNNEL. Morton Cooper and John R. Sevier, Jr. January 1953. 19p. diagrs., tab. (NACA TN 2856)

A simplified analysis has been made to estimate the extent to which the pressure ratio and power of a nonreturn supersonic wind tunnel operating in the low supersonic Mach number range can be reduced by the evaporation of water injected into the diffuser. It appears to be theoretically possible to reduce the power by as much as 20 percent for a typical example of a tunnel operating at a Mach number of 1.4 and at the following stagnation conditions: pressure, 15 pounds per square inch; temperature, 200° F; and dew point, 0° F or less. For a tunnel having a test section of 50 square feet, the amount of water injected would be about 300 gallons per minute and the power saved, about 7,000 horsepower. The power required to provide the necessary water and the possible increases in diffuser losses associated with water injection must, of course, be weighted against the theoretical power saving.

NACA TN 2864

CONVECTION OF A PATTERN OF VORTICITY THROUGH A SHOCK WAVE. H. S. Ribner. January 1953. ii, 48p. diagrs. (NACA TN 2864)

An arbitrary weak spatial distribution of vorticity can be represented in terms of plane sinusoidal shear waves of all orientations and wave lengths (Fourier integral). The analysis treats the passage of a single representative weak shear wave through a plane shock and shows refraction and modification of the shear wave with simultaneous generation of an acoustically intense sound wave. Applications to turbulence and to noise in supersonic wind tunnels are indicated.

NACA TN 2865

INVESTIGATION OF GASES EVOLVED DURING FIRING OF VITREOUS COATINGS ON STEEL.

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

Dwight G. Moore and Mary A. Mason, National Bureau of Standards. January 1953. 34p. diagrs., photos., 7 tabs. (NACA TN 2865)

A study was made of the nature and source of gases evolved when a ground-coat enamel is applied to low-carbon steel. The principal gases evolved were found to be carbon monoxide, carbon dioxide, and hydrogen. The cause of primary boil was determined as the evolution of carbon gases from the oxidation of carbon in the steel. Further results indicate that hydrogen, formed from the reaction between dissolved water in the coating and the hot iron base, diffuses into the coating as firing continues. On fast cooling the hydrogen is expelled causing bubbles to form at the interface of the coating. Practically all of the bubble structure in a normally fired enamel was found to be due to some impurity in the clay addition which may be organic matter adsorbed on the clay particles.

NACA TN 2868

REFLECTION OF A WEAK SHOCK WAVE FROM A BOUNDARY LAYER ALONG A FLAT PLATE. I - INTERACTION OF WEAK SHOCK WAVES WITH LAMINAR AND TURBULENT BOUNDARY LAYERS ANALYZED BY MOMENTUM-INTEGRAL METHOD. Alfred Ritter and Yung-Huai Kuo, Cornell University. January 1953. 66p. diagrs., tab. (NACA TN 2868)

The present paper is concerned with the phenomena encountered when a plane oblique shock wave is incident upon the boundary layer of a flat plate. The problem has been simplified by dividing the flow field into a viscous layer near the wall and a supersonic potential outer flow. Ordinary linearized theory has been applied to the outer flow inasmuch as the study has been restricted to infinitesimal compression waves and only small perturbations are encountered. The paper deals primarily with the case of laminar flow and the boundary-layer treatment is based upon the momentum-integral equation previously derived by Howarth.

NACA TN 2869

REFLECTION OF WEAK SHOCK WAVE FROM A BOUNDARY LAYER ALONG A FLAT PLATE. II - INTERACTION OF OBLIQUE SHOCK WAVE WITH A LAMINAR BOUNDARY LAYER ANALYZED BY DIFFERENTIAL-EQUATION METHOD. Yung-Huai Kuo, Cornell University. January 1953. 60p. diagrs. (NACA TN 2869)

By analogy with the boundary-layer concept, the flow produced by the interaction between a shock wave and a laminar boundary layer is subdivided into a viscous layer and a potential field. The assumptions that the compressibility effect in the inner layer is negligible and that the original flow in the outer layer is uniform lead to simple analytical solutions using a differential-equation method to determine the perturbed flow. The joining conditions at the interface between the layers determine an eigenvalue which gives the rate of decay and the character of the disturbances both upstream and downstream of the point of incidence.

NACA TN 2870

POWER-OFF FLARE-UP TESTS OF A MODEL HELICOPTER ROTOR IN VERTICAL AUTOROTATION. S. E. Slaymaker and Robin B. Gray, Princeton University. January 1953. 36p. diagrs., photos. (NACA TN 2870)

The problem of reducing the descending velocity of a helicopter model in steady vertical autorotation by expending the kinetic energy of the rotor in a collective-pitch flare was investigated experimentally. Test data were obtained over a wide range of operating conditions from a freely falling model rotor restrained laterally by a guide wire. The results indicate the influence of disk loading and rotor inertia on a given rotor configuration under various flare conditions. A semiempirical method was developed for predicting the flare performance of the model. The accuracy of the method was checked experimentally for all model configurations and sample calculations were made for two full-scale helicopters. The method yields results which compare favorably with experimental data.

NACA TN 2871

EXPERIMENTAL INVESTIGATION OF LOSS IN AN ANNULAR CASCADE OF TURBINE-NOZZLE BLADES OF FREE VORTEX DESIGN. Hubert W. Allen, Milton G. Kofskey and Richard E. Chamness. January 1953. 33p. diagrs., photos., tab. (NACA TN 2871)

Losses originating in a cascade of turbine-nozzle blades of free-vortex design were investigated quantitatively at two Mach numbers, and visual studies were also made of the boundary-layer flow on blade and shroud surfaces. High loss regions were found near the corners between the suction side of the wake and the shrouds. These losses were accompanied by high discharge-angle gradients. Visual traces of shroud boundary-layer flow showed a cross-channel component of velocity and indicated one source fo the accumulation of low-momentum fluid comprising the loss region. Results of a shift of the loss region and visual indications of the boundary-layer flow along the blade surfaces at the higher Mach number showed that the low-momentum fluid originating on the outer shroud and blade surfaces flows radially inward through a thickened portion of the boundary layer on the blade suction surface and along the trailing edge in the wake of the blades.

NACA TN 2872

THE EFFECT OF INITIAL CURVATURE ON THE STRENGTH OF AN INELASTIC COLUMN. Thomas W. Wilder, III, William A. Brooks, Jr., and Eldon E. Mathauser. January 1953. 17p. diagrs. (NACA TN 2872)

The reduction in column strength due to initial curvature is determined theoretically for a pin-ended idealized inelastic H-section column. Equations

relating load and lateral deflection are obtained which permit a systematic variation in the parameters representing the stress-strain properties, column proportions, and initial curvature of the column. The results, presented graphically, show the effect on column strength for various combinations of these parameters.

NACA TN 2873

THE EFFECT OF LONGITUDINAL STIFFENERS LOCATED ON ONE SIDE OF A PLATE ON THE COMPRESSIVE BUCKLING STRESS OF THE PLATE-STIFFENER COMBINATION. Paul Seide. January 1953. 66p. diagrs., 2 tabs. (NACA TN 2873)

The problem of buckling under uniform compression of flat, simply supported, rectangular plates with equally spaced longitudinal stiffeners on one side of the plate is investigated. For the case of a plate with one, two, or infinitely many stiffeners, the analysis yields expressions for the effective moment of inertia of the stiffeners that can be used in conjunction with the buckling charts previously presented in NACA TN 1825.

NACA TN 2874

ON TRAVELING WAVES IN BEAMS. Robert W. Leonard and Bernard Budiansky. January 1953. 76p. diagrs., tab. (NACA TN 2874)

The basic equations of Timoshenko for the motion of vibrating nonuniform beams, which allow for effects of transverse shear deformation and rotary inertia, are presented in several forms; the propagation of sharp disturbances is discussed. Numerical traveling-wave solutions are obtained for some elementary problems of finite uniform beams for which the propagation velocities of shear and bending discontinuities are equal. Comparisons are made with modal solutions and, in some cases, with exact closed solutions.

NACA TN 2875

BEHAVIOR IN PURE BENDING OF A LONG MONOCOQUE BEAM OF CIRCULAR-ARC CROSS SECTION. Robert W. Fralich, J. Mayers and Eric Reissner. January 1953. 33p. diagrs. (NACA TN 2875)

An analysis is made of the behavior under a loading of pure bending moment of a thin, infinitely long, pure-monocoque beam having a constant, doubly symmetric, circular-arc cross section. Bending moments, deflections, and stresses are obtained. The analysis shows a nonlinear behavior in bending which leads ultimately to a maximum moment and instability.

NACA TN 2876

THE PLANING CHARACTERISTICS OF TWO V-SHAPED PRISMATIC SURFACES HAVING ANGLES OF DEAD RISE OF 20° and 40°. Derrill B. Chambliss and George M. Boyd, Jr. January 1953. 38p. diagrs., photos., 2 tabs. (NACA TN 2876)

An investigation was conducted to determine the principal planing characteristics of two V-shaped surfaces having angles of dead rise of 20° and 40°. The data indicate that, for a given condition of load, speed, and trim, the wetted length, distance of center of pressure from trailing edge, and drag increase with an increase in the angle of dead rise.

NACA TN 2877

ON THE USE OF A DAMPED SINE-WAVE ELEVATOR MOTION FOR COMPUTING THE DESIGN MANEUVERING HORIZONTAL-TAIL LOAD. Melvin Sadoff. January 1953. 32p. diagrs., 3 tabs. (NACA TN 2877)

An analysis was made to evaluate the assumption of a damped sine-wave elevator motion for computing the design maneuvering load on the horizontal tail. Also investigated was the effect of control frequency on the tail load. The results indicated that the tail loads computed by the method of the present report agreed closely with the loads computed by a method currently specified for use in the U.S. Air Force structural loading requirements. For a given design normal acceleration factor, it was found that an increase in control frequency resulted in a marked increase in both the negative and positive peak tail loads attained during the assumed maneuvers.

NACA TN 2878

COMBINED EFFECT OF DAMPING SCREENS AND STREAM CONVERGENCE ON TURBULENCE. Maurice Tucker. January 1953. i, 62p. diagrs., tab. (NACA TN 2878)

The analysis treats, in the absence of turbulent decay processes, the combined effect of a series of identical damping screens followed by a stream convergence upon the mean-square fluctuation velocities, scales, correlation coefficients, and one-dimensional spectra of a convected field of turbulence described by a triple Fourier integral superposition of plane transverse waves. Numerical results are tabulated for the case of upstream isotropic turbulence. An approximate method for taking into account the effects of turbulent decay upon the mean-square fluctuation velocities is also presented.

NACA TN 2879

UNSTEADY OBLIQUE INTERACTION OF A SHOCK WAVE WITH A PLANE DISTURBANCE. Franklin K. Moore. January 1953. 66p. diagrs. (NACA TN 2879)

Analysis is made of the flow field produced by oblique impingement of weak plane disturbances of arbitrary profile on a plane normal shock. Three types of distrubance are considered: (a) Sound wave propagating in the gas at rest into which the shock moves. The sound wave refracts either as a simple isentropic sound wave or an attenuating isentropic pressure wave, depending on the angle between the shock and the incident sound wave. A stationary vorticity wave of constant pressure appears behind the shock. (b) Sound wave overtaking the shock from behind. The sound wave reflects as a sound wave, and a stationary vorticity wave is produced. (c) An incompressible vorticity wave stationary in the gas ahead of the shock. The incident wave refracts as a stationary vorticity wave, and either a sound wave or attenuating pressure wave is also produced. Computations are presented for the first two types of incident wave, over the range of incidence angles, for shock Mach numbers of 1, 1.5, and ∞.

NACA TN 2880

A DIGITAL AUTOMATIC MULTIPLE PRESSURE RECORDER. Bert A. Coss, D. R. Daykin, Leonard Jaffe and Elmer M. Sharp. January 1953. 24p. diagrs., photo. (NACA TN 2880)

A machine is described which will automatically measure and record 100 pressures in a range from 5 to 65 inches of mercury, in approximately 2-1/2 minutes, to an accuracy of 0.1 inch of mercury. The method used is to compare the unknown pressures with a scanning pressure whose value at any instant is known in digitalized form. Sensitive diaphragms indicate balance between the unknown and the scanning pressures. All unknown pressures are compared with the scanning pressure simultaneously and the information is stored temporarily within the machine. During read out, the information is properly sequenced, identified, coded, and punched into paper tape, which is the actual permanent record of the output of the machine, although typewritten tabulated data may also be produced. The punched paper tape may be used subsequently either to tabulate data or to punch cards automatically for use in punched-card calculators.

NACA TN 2882

THEORETICAL INVESTIGATION OF THE LONGITUDINAL RESPONSE CHARACTERISTICS OF A SWEPT-WING FIGHTER AIRPLANE HAVING A PITCH-ATTITUDE CONTROL SYSTEM. Fred H. Stokes and J. T. Matthews. January 1953. 41p. diagrs., tab. (NACA TN 2882)

An analysis is made of a pitch-attitude control system, both with and without rate feedback, as applied to a swept-wing fighter airplane. The results show the response characteristics of the airplane-autopilot combination. The effects that changes in altitude and Mach number have on these response characteristics are investigated, as are the effects of changes in the rate and error gain settings of the system.

NACA TN 2883

BEARING STRENGTHS OF SOME 75S-T6 AND 14S-T6 ALUMINUM-ALLOY HAND FORGINGS. E. M. Finley, Aluminum Company of America. January 1953. 24p. diagrs., photos., 4 tabs. (NACA TN 2883)

Results are given from an investigation of bearing properties of some 75S-T6 and 14S-T6 aluminum-alloy hand forgings in the longitudinal and long transverse directions and in surface and center locations. The tensile properties of the forgings were above those specified for such material and showed the expected directional or locational characteristics. The bearing properties showed less directional or locational variations than did the tensile properties. Ratios of bearing to longitudinal tensile strengths are summarized and nominal values are recommended for use in selecting design bearing strengths.

NACA TN 2887

ON THE STABILITY OF THE LAMINAR MIXING REGION BETWEEN TWO PARALLEL STREAMS IN A GAS. C. C. Lin, Massachusetts Institute of Technology. January 1953. 50p. diagrs., 5 tabs. (NACA TN 2887)

A study was made of the stability of the mixing of two parallel streams in a gas. It is shown that, when the relative speed of the two parallel streams exceeds the sum of their velocities of sound, subsonic oscillations cannot occur and the mixing region may be expected to be stable with respect to small disturbances. It is further shown that, when viscosity and heat conductivity are neglected, if the flow can execute a small neutral subsonic disturbance it can also execute self-excited oscillations of longer wave lengths and damped oscillations of shorter wave lengths. Additional developments of the mathematical theory of asymptotic solutions showed that, at high Reynolds numbers, the damped oscillations in a strictly parallel main flow have a structure similar to that of the vorticity field in fully developed flow.

NACA TM 1342

SPIRAL MOTIONS OF VISCOUS FLUIDS. (Spiralförmige Bewegungen zäher Flüssigkeiten). Georg Hamel. January 1953. 44p. (NACA TM 1342. Trans. from Deutsche Mathematiker-vereinigung, Jahresbericht, v. 25, 1917, p. 34-60).

Exact solutions of the steady incompressible viscous flow equations are obtained. The streamlines corresponding to such solutions are in general logarithmic spirals. The more specific cases of purely concentric and purely radial flows are fully investigated. Corresponding to the radial flows are the physically important cases of flow in radially convergent channels and in divergent channels. A second method is used to investigate exact steady and unsteady two-dimensional motions in free spirals. Neighborhood solutions to the radial flow are also discussed.

THE CURRENT AND VOLTAGE RELATIONSHIPS OF A STABLE D.C. ARC BETWEEN COPPER ELECTRODES IN AIR AT 4-760 MM. HG. I. A. Mossop and F. D. Gill. May 1952. 53p. diagrs., photos., 14 tabs. (RAE EL. 1477)

This report describes a method that has been developed for measuring the current and voltage characteristics of a stable d-c arc. The arc is formed between stationary electrodes by first breaking down the gap using a high voltage capacitor discharge. This discharge is allowed to develop into a power arc which is then maintained by a 120 volts accumulator supply. The arc current and voltage are measured on peak voltmeters which are switched into the circuit only after the arc has become stable. Switching is done automatically by a "sequence controller" which also opens the main circuit breaker as soon as the measurements have been made. In this way electrode wear is reduced to a minimum. The methods of previous workers using oscillographic-film techniques are reviewed critically; the advantages of the new method of measurement are great saving in time and labor, increased accuracy due to the measurement of true stable arc characteristics, and freedom from the complications of moving electrodes such as the measurement of instantaneous gap length. An appendix describes a statistical method of analyzing the experimental results which, apart from minimizing the troublesome effects of random scatter on the analysis, ends by giving the results in the form of a single expression which has been presented as a nomograph. This research is part of a general program of investigation of the effects of reduced gas pressure on the behavior of an arc. This report gives the results that have been obtained for copper electrodes in air in the pressure range 4-760 mm Hg at currents between 1 and 17 amps and for gaps up to 2 mm in length.

NOTES ON TRANSDUCTOR DESIGN AND CORE MATERIALS. A. G. Milnes and A. R. George. August 1952. 31p. diagrs., 4 tabs. (RAE Tech.Note EL.40)

Transductor performance with Mumetal or silicon-iron cores is examined for a series circuit with complete self-excitation, and design data are obtained for 50, 400 and 1600 c/s operation. The influence of supply voltage or core flux density on the sensitivity and linearity is examined. The results are compared with experiments reported earlier with crystalloy and H.C.R. cores. Three design methods are described: one is based on idealized theoretical equations, another on load line techniques, and the third is based on the similarity in shape of the transductor characteristic to the B-H curve of the core. A specimen design calculation is given to illustrate the use of the design data. The methods described are applicable to both separately excited and auto-self-excited types of connections.

Marine Aircraft Experimental Establishment (Gt. Brit.) THE M.A.E.E. RECORDING ACCELEROMETER. D. M. Ridland and R. Parker. September 1952. 15p. diagrs., photos. (MAEE F/Res/226)

The M.A.E.E. recording accelerometer is basically the accelerometer unit of a desynn accelerometer, adapted to make a continuous and immediate presentation of accurate, calibrated accelerations on a half second time base. The recording medium is metallized paper, having a speed of half an inch per second, and the instrument can be operated continuously for twenty minutes on one loading. It can record with full scale deflections, from 1g to 10g, when the natural frequencies will be about 7 and 22 c.p.s. respectively. The instrument is simple, it has been proved reliable and accurate and it is most convenient in use.

THE TWO-DIMENSIONAL FLOW OF AN INCOMPRESSIBLE FLUID ABOUT AN AEROFOIL BY THE "INFLUENCE FACTORS" METHOD. L. C. Woods. October 19, 1950. 18p., 3 tabs. (ARC 13,460; FM 1489; Oxford Univ., Engineering Lab. No. 38)

This report describes an exact method of calculating the two-dimensional flow of an incompressible fluid about either a symmetrical or an asymmetric airfoil. The method enables the flow to be calculated at any point in the field. It was originated by Thom, and termed by him "the influence factor method." In this paper, his work on symmetrical airfoils is extended to asymmetric airfoils, and his approximate equations for the bounded stream are replaced by the exact forms.

STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART VI. IGNITION DELAY MEASUREMENTS ON ORGANIC COMPOUNDS CONTAINING NITROGEN OR HALOGEN. B. P. Mullins. July 1952. 58p. diagrs., 36 tabs. (NGTE R.106)

Ignition delay measurements have been made upon a number of organic compounds containing nitrogen or halogen using the continuous flow method of test and the nitrogen pressurized fuel system previously described. The present report is mainly a catalogue of the experimental results. The fuels tested may be grouped in the following classes: miscellaneous nitrogen compounds, nitro compounds, nitrite esters, nitrate esters, aliphatic amines, aromatic amines, aliphatic halogen compounds, and aromatic halogen compounds. Acetonitrile is the least ignitable and n-butyl nitrite is the most ignitable of the fuels examined in the test rig. Flame observations were made and activation energies of reaction were computed for each fuel.

STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART VII. IGNITION DELAY MEASUREMENTS ON ALCOHOLS AND ETHERS. B. P. Mullins. July 1952. 55p. diagrs., 32 tabs. (NGTE R. 107)

Ignition delay measurements have been made upon a number of alcohols and ethers using the continuous flow method of test and nitrogen-pressurized fuel system previously described, and the present report is mainly a catalogue of the experimental results. The fuels tested may be grouped in the following classes: saturated aliphatic alcohols, miscellaneous alcohols, aliphatic ethers, glycol ethers, and miscellaneous ethers. Furfuryl alcohol is the most ignitable and m-cresol is the least ignitable of the alcohols examined. The ignitability of the n-paraffin alcohols increases as the homologous series is ascended. Propylene oxide is the most ignitable and and di-isopropyl ether is the least ignitable of the ethers examined. Flame observations were made and activation energies of reaction were computed for each fuel.

National Gas Turbine Establishment (Gt. Brit.)
STUDIES ON THE SPONTANEOUS IGNITION OF FUELS INJECTED INTO A HOT AIR STREAM. PART VIII. IGNITION DELAY MEASUREMENTS ON ALDEHYDES, KETONES, ESTERS, CYCLO-COMPOUNDS, HETEROCYCLIC COMPOUNDS AND CARBON DISULPHIDE. B. P. Mullins. July 1952. 79p. diagrs., 28 tabs. (NGTE R. 108)

Ignition delay measurements have been made upon a number of miscellaneous organic compounds using the continuous flow method of test and nitrogen pressurized fuel system previously described and the present report is mainly a catalogue of the experimental results. The fuels tested may be grouped in the following classes: aldehydes, ketones, acetates, miscellaneous esters, cyclo-compounds, furan and its derivatives, miscellaneous heterocyclic compounds, and carbon disulphide. Acrolein is the most ignitable and acetaldehyde is the least ignitable of the aldehydes examined. Diacetyl is the most ignitable and acetone is the least ignitable of the ketones examined. The ignitability of the aliphatic acetates increases as the homologous series is ascended. Carbon disulphide is more ignitable than any of the aldehydes, ketones or acetates tested; at 650° C it has an ignition delay of 11 milliseconds in vitiated air. Flame observations were made and activation energies of reaction were computed for each fuel.

GRAVINER STRIP-TYPE CONTACT SWITCHES FOR OPERATION OF AIRCRAFT FIRE EXTINGUISHING

SYSTEMS IN CRASHES. NOTE ON A SIMULATED CRASH-LANDING TEST. E. Bade and I. S. H. Brown. September 1952. 10p. diagrs., photos. (RAE Tech. Note Mech. Eng. 134)

The development of aircraft fire extinguishing systems has included a simulated crash test using a Seafire aircraft to check the performance of a strip-type contact switch developed by the Graviner Manufacturing Co. The contact switch is intended for use in addition to, or as a replacement of, the conventional inertia-types of crash switch which, because of their necessarily high "g" setting, frequently fail to function in crashes of moderate severity. The trial was arranged so that a comparison could be made of the behavior of the strip-type contact switches against the pendulum- and piston-type switches. The results have shown that the contact switch will operate instantly and effectively in a crash landing in which impact is made on the switch. Installation of the contact switch on the surfaces of high-speed aircraft would incur no significant aerodynamic penalty and it appears that both for practical and psychological reasons its adoption for service aircraft would be advantageous. To this end a specification of service requirements is being prepared to enable acceptance tests to be carried out.

CURRENT NACA REPORTS

NACA Rept. 1069

ON A SOLUTION OF THE NONLINEAR DIFFERENTIAL EQUATION FOR TRANSONIC FLOW PAST A WAVE-SHAPED WALL. Carl Kaplan. 1952. ii, 11p. diagrs., tab. (NACA Rept. 1069. Formerly TN 2383)

The simplified nonlinear differential equation for transonic flow past a wavy wall is solved by the method of integration in series. The solution has been carried to the point where the question of the existence or nonexistence of a mixed potential flow can be answered by the behavior of a single power series in the transonic similarity parameter. The calculation of the coefficients of this dominant power series has been reduced to a routine computing problem by means of recursion formulas resulting from the solution of the differential equation and the boundary condition at the surface of the wavy wall.

NACA Rept. 1071

THEORETICAL SYMMETRIC SPAN LOADING DUE TO FLAP DEFLECTION FOR WINGS OF ARBITRARY PLAN FORM AT SUBSONIC SPEEDS. John DeYoung. 1952. ii, 41p. diagrs., tabs. (NACA Rept. 1071. Formerly NACA TN 2278)

A procedure based upon a simplified lifting-surface theory that includes effects of compressibility and spanwise variation of section lift-curve slope is presented in such a manner that the spanwise loading due to flap deflection can be simply found for wings having symmetric plan forms with constant spanwise sweep angle of the quarter-chord line. Aerodynamic characteristics due to flap deflection are considered and for straight-tapered wings, values of certain of these characteristics are presented in charts for a range of swept plan forms. Further use of the method gives downwash in the vertical center of the wake of the wing.

NACA Rept. 1083

AXISYMMETRIC SUPERSONIC FLOW IN ROTATING IMPELLERS. Arthur W. Goldstein. 1952. ii, 14p. diagrs. (NACA Rept. 1083. Formerly TN 2388)

General equations are developed for isentropic, frictionless, axisymmetric compressible flow in rotating impellers with blade forces eliminated in favor of the blade-surface function. The characteristic equations for supersonic flow are developed and a computing technique is utilized to find the effect of variations of design parameters on internal flow and work-input distribution.

NACA TN 2881

AERODYNAMIC CHARACTERISTICS OF A TWO-BLADE NACA 10-(3)(062)-045 PROPELLER AND OF A TWO-BLADE NACA 10-(3)(08)-045 PROPELLER. William Solomon. January 1953. 53p. diagrs., photo., tab. (NACA TN 2881. Formerly RM L8E26)

Characteristics are given for the two-blade NACA 10-(3)(062)-045 propeller and for the two-blade NACA 10-(3)(08)-045 propeller over a range of advance ratio from 0.5 to 3.8, through a blade-angle range from 20° to 55° measured at the 0.75 radius. Maximum efficiencies of the order of 91.5 to 92 percent were obtained for the propellers. The propeller with the thinner airfoil sections over the outboard portion of the blades, the NACA 10-(3)(062)-045 propeller, had lower losses at high tip speeds, the difference amounting to about 5 percent at a helical tip Mach number of 1.10.

NACA TN 2884

CALCULATION AND MEASUREMENT OF NORMAL MODES OF VIBRATION OF AN ALUMINUM-ALLOY BOX BEAM WITH AND WITHOUT LARGE DISCONTINUITIES. Frank C. Smith and Darnley M. Howard, National Bureau of Standards. January 1953. 40p. diagrs., photo., 8 tabs. (NACA TN 2884)

The lowest normal modes of vibration of three aluminum alloy box beams were calculated using a matrix iteration method. For the calculations the actual structures were idealized to a system of mass points interconnected by massless springs. The lowest normal modes of these beams were measured experimentally and compared with those calculated. This comparison indicates that the mode shapes and natural frequencies for structures of this type may be adequately calculated using this method. The experimental measurements were limited at the higher frequencies by local vibrations of small elements of the beams.

NACA TN 2885

SOME EXACT SOLUTIONS OF TWO-DIMENSIONAL FLOWS OF COMPRESSIBLE FLUID WITH HODOGRAPH METHOD. Chieh-Chien Chang and Vivian O'Brien, Johns Hopkins University. February 1953. 63p. diagrs., 4 tabs. (NACA TN 2885)

*AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A suggestion is given for classifying compressible potential flows according to location and number of singularities in the subsonic region of the hodograph plane, which seems to offer a convenient criterion for systematic investigation of these flows with Chaplygin's original method. The object of the paper is to present and analyze a few useful solutions of compressible potential flow with the exact gas law. These solutions include flows about convex corners and belong to the same class as that of Ringleb. Also, the exact solution of compressible flow through a particular contracting channel is given.

NACA TN 2886

AN ANALYSIS OF STATICALLY INDETERMINATE TRUSSES HAVING MEMBERS STRESSED BEYOND THE PROPORTIONAL LIMIT. Thomas W. Wilder, III. February 1953. 13p. diagrs., 4 tabs. (NACA TN 2886)

A procedure for analyzing statically indeterminate trusses in the plastic stress range is presented which is applicable to trusses having any number of redundant members. By using the Ramberg-Osgood analytical representation of the stress-strain curve, the analysis of the truss is reduced to the solution of a set of simultaneous equations. A numerical example is presented to illustrate the procedure.

NACA TN 2888

PERFORMANCE CHARACTERISTICS OF PLANE-WALL TWO-DIMENSIONAL DIFFUSERS. Elliott G. Reid, Stanford University. February 1953. i, 80p. diagrs., photos., 3 tabs. (NACA TN 2888)

Performance characteristics were determined for plane-wall, two-dimensional diffusers which were so proportioned as to insure reasonable approximation of two-dimensional flow. The diffusers had identical entrance cross sections and discharged directly into a large plenum chamber; the test program included wide variations of divergence angle and length. A dynamic pressure of 60 pounds per square foot was maintained at the diffuser entrance and the boundary layer there was thin and fully turbulent. A few tests were made with asymmetric diffusers. Others showed the effects of addition of a short exit duct of uniform section and of installation of a thin, central, longitudinal partition.

NACA TN 2891

FACTORS AFFECTING LAMINAR BOUNDARY LAYER MEASUREMENTS IN A SUPERSONIC STREAM. Robert E. Blue and George M. Low. Appendix B: REDUCTION OF DATA. Jack M. Lande. February 1953. 49p. diagrs. (NACA TN 2891)

The observed discrepancy at supersonic speeds between theoretical and apparent experimental average flat plate friction-drag coefficients calculated from boundary layer total-pressure surveys was investigated. Effects of the total-pressure probe, heat transfer through the leading-edge region, leading-edge geometry and strength of the leading-edge wave, possible early transition to turbulent flow or "bursts of turbulence," and the slight streamwise pressure gradient inherent in flat-plate flow were included in the investigation. Only one of these factors, the effect of the total-pressure probe, was found to be significant. Total-pressure probes of different tip heights, when placed in laminar boundary layers developing under identical conditions, measure different values of friction-drag coefficient. Extrapolation of these measurements indicates that a probe of vanishing tip height would measure the theoretically predicated values of average flat plate friction-drag coefficients.

NACA TN 2894

CALCULATIONS OF UPWASH IN THE REGION ABOVE OR BELOW THE WING-CHORD PLANES OF SWEPT-BACK WING-FUSELAGE-NACELLE COMBINATIONS. Vernon L. Rogallo and John L. McCloud, III. February 1953. 15p. diagrs., photo. (NACA TN 2894)

A procedure has been developed for predicting the upwash components of the upflow angles in the region above or below the wing-chord planes of swept-back wing-fuselage-nacelle combinations. Comparisons are made of the predicted and measured upflow angles for six semispan models with 40° swept-back wings.

NACA TN 2896

SURVEY OF PORTIONS OF THE IRON-NICKEL-MOLYBDENUM AND COBALT-IRON-MOLYBDENUM TERNARY SYSTEMS AT 1200° C. Dilip K. Das and Paul A. Beck, University of Notre Dame. February 1953. 56p. diagrs., photos., 15 tabs. (NACA TN 2896)

The 1200° C isothermal sections of the iron-nickel-molybdenum and the cobalt-iron-molybdenum ternary systems were surveyed. The phases occurring in these systems were identified by means of X-ray diffraction and by etching methods, and the phase boundaries at 1200° C were determined microscopically, using the disappearing phase method with quenched specimens. Both systems contain long solid-solution fields of the mu phase. Other intermediate phases occurring in the iron-nickel-molybdenum system are the P phase and the delta phase. Both phase diagrams have extensive face-centered cubic solid-solution fields and some body-centered cubic solid solutions.

NACA RM E52L09

FORCED-CONVECTION HEAT-TRANSFER CHARACTERISTICS OF MOLTEN SODIUM HYDROXIDE. Milton D. Grele and Louis Gedeon. February 1953. 27p. diagrs., photo., 2 tabs. (NACA RM E52L09)

The forced-convection heat-transfer characteristics of sodium hydroxide were experimentally investigated. The heat-transfer data for heating fall slight-

ly above the McAdams correlation line, and the heat-transfer data for cooling are fairly well represented by the McAdams correlation line.

NACA TM 1344

ON THE THEORY OF THE TURBULENT BOUNDARY LAYER. (Über die Theorie der turbulenten Grenzschichten). J. Rotta. February 1953. 50p. diagrs. (NACA TM 1344. Trans. from Max-Planck-Institut für Strömungsforschung, Göttingen. Mitteilungen 1, 1950)

Turbulent energy, dissipation, and momentum relations are discussed. A procedure is given for computation of turbulent skin friction in boundary-layer flow with pressure gradients. The boundary layer is divided into a region near the wall where viscosity and surface roughness are important, an outer region which is dependent on friction coefficient and pressure gradient, and an intermediate zone between these two which is unaffected by wall roughness, viscosity, and the outer flow. Analytical confirmation is obtained for the empirical fact that turbulent boundary layers are able to overcome a greater pressure rise than laminar ones.

NACA TM 1349

ON A CLASS OF EXACT SOLUTIONS OF THE EQUATIONS OF MOTION OF A VISCOUS FLUID. (Ob odnom klasse tochnykh reshenii uravnenii dvizheniya vyazkoi zhidkosti). V. I. Yatseyev. February 1953. 7p. (NACA TM 1349. Trans. from Zhurnal Eksperimental 'noi i Teoretisheskoi Fiziki, v. 20, no. 11, 1950, p. 1031-1034).

The general solution is obtained of the equations of motion of a viscous fluid in which the velocity field is inversely proportional to the distance from a certain point. Some particular cases of such motion are investigated.

NACA TM 1358

CALCULATION OF THE SHAPE OF A TWO-DIMENSIONAL SUPERSONIC NOZZLE IN CLOSED FORM. (Sul Calcolo in Termini Finiti dell'Effusore di una Galleria Bidimensionale Supersonica). Dante Cunsolo. January 1953. 29p. diagrs. (NACA TM 1358. Trans. from Aerotecnica, v. 31, no. 4, August 15, 1951, p. 225-230).

The idea is advanced of making a supersonic nozzle by producing one, two, or three successive turns of the whole flow; with the result that the wall contour can be calculated exactly by means of the Prandtl-Meyer "Lost Solution."

NOTE ON PROFILE DRAG CALCULATIONS FOR LOW-DRAG WINGS WITH CUSPED TRAILING EDGES. R. C. Lock. 1952. 10p. diagrs., tab. (ARC R & M 2419; ARC 9772. Formerly RAE Aero 2130)

In R. & M. 1833 calculations of profile drag were made based on wing sections of conventional design, and were later extended in an Addendum to "low-drag" wing sections with convex trailing edges. Further calculations were required for low-drag sections of more recent design with cusped trailing edges. This report presents calculations made on sections of the NACA 65-family of thickness 0.12c and 0.23c with maximum thickness at 0.4c from the leading edge, over a range of Reynolds number and position of the transition points.

MODEL TESTS WITH FLOW ON THE GLOSTER F.9/40 WITH H.1 NACELLES (METEOR II). J. S. Thompson, C. M. Fougere and E. G. Barnes. 1952. 17p. diagrs., 14 tabs. (ARC R & M 2517; ARC 6901. Formerly RAE Aero 1821)

For an earlier estimate by Thompson and Barnes of the longitudinal stability of the F.9/40 in flight, it was necessary to extrapolate for the higher values of C_L, because the maximum jet flow from model tests then available was that appropriate to a C_L of only 0.2, ground level. The purpose of the tests described in this note was to extend the previous model tests, using a considerably larger flow, to enable more precise estimates to be made. Measurements were made of lift, drag, pitching and yawing moments for jet flows up to an exit v/V of 4.5 and at various tunnel speeds.

THE DESIGN AND INSTALLATION OF SMALL COMPRESSED AIR TURBINES FOR TESTING POWERED DYNAMIC MODELS IN THE ROYAL AIRCRAFT ESTABLISHMENT SEAPLANE TANK. D. I. T. P. Llewelyn-Davies, W. D. Tye and D. C. MacPhail. 1952. 19p. diagrs., photos., tab. (ARC R & M 2620; ARC 10,812. Formerly RAE Aero 2192)

This report describes the development of small lightweight air turbines for powering dynamic models in the R.A.E. seaplane tank. The units have proved to be rugged and reliable and power/weight ratios of 0.4 lb/bhp have been achieved. The installation of the turbines in dynamic models and the provision of their air supply are also discussed.

ON THE SOLUTION OF LINEAR SIMULTANEOUS DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS BY A PROCESS OF ISOLATION. J. Morris. 1952. 7p. (ARC R & M 2623; ARC 11,420. Formerly RAE SME 4036)

In this report, a process is given for the solution of linear differential equations with constant coefficients. The operative artifice is closely akin to Routh's method of isolation by means of which the constants of integration are found separately for each root of the characteristic equations.

Aeronautical Research Council (Gt. Brit.)
THE DYNAMIC LANDING LOADS OF FLYING BOATS WITH SPECIAL REFERENCE TO MEASUREMENTS MADE ON SUNDERLAND TX. 293. Anne Burns and A. J. Fairclough. 1952. 38p. diagrs., photos., 2 tabs. (ARC R & M 2629; ARC 11,344. Formerly RAE Structures 17)

An account is given of a full-scale investigation into the stresses occurring in the wing members of a Sunderland flying boat during landing impacts. It is found that the main dynamic effect is caused by the wing oscillating in its fundamental mode. These dynamic loads have a spanwise distribution similar to the normal lift load and, if the level flight lift load is taken as unity, a magnitude (in the most severe impact recorded) of 1.4 upwards and 1.5 downwards. Generalizing this result, one concludes that whereas down loads in landing may be a deciding factor in design the up loads are amply covered by existing requirements. Comparison of calculated and experimental loads found in these tests indicates that satisfactory agreement can be attained by using recently introduced modifications of standard dynamical methods. Although the investigation is primarily a structural one some interesting results on general water load phenomena are obtained.

Aeronautical Research Council (Gt. Brit.)
LOAD DIFFUSION AT AN INTERSPAR OPENING: THEORETICAL METHODS OF ANALYSIS COMPARED WITH STRAIN MEASUREMENTS ON A LARGE WING. D. C. Allen. 1952. 26p. diagrs., 6 tabs. (ARC R & M 2664; ARC 11,731. Formerly RAE Structures 30)

The diffusion of load from spar flanges into skin and stringers near an opening was investigated experimentally in a large wing structure undergoing strength tests. A comparison of measured strains with those given by theoretical methods shows that in general the flange loads are represented with reasonable accuracy. Any theory, however, in which the chordwise rib at the edge of the opening is ignored gives shear stresses much greater than those measured. Allowance for the bending stiffness of this rib produces values of shear stress comparable with those obtained experimentally.

Aeronautical Research Council (Gt. Brit.)
LANDING GEAR WITH TWIN TANDEM WHEEL UNITS: CORNERING CHARACTERISTICS AS DETERMINED BY MODEL TESTS. J. W. Blinkhorn. 1952. 7p. diagrs., photos., tab. (ARC R & M 2668; ARC 11,850. Formerly RAE Tech. Note Mech. Eng. 18)

For twin tandem units, the wheel loading conditions which arise when aircraft are turned on the ground may be critical for the landing gear. To estimate the magnitude of these loads, cornering tests were made on a small-scale model of the main undercarriage unit proposed for the Brabazon I, MK. II. These tests showed that for zero turning radius, that is, turning about the central vertical axis of the model undercarriage, the wheel side loads were almost equal to the vertical load multiplied by the coefficient of sliding friction between the tires and the ground. The side loads rapidly decreased as the turning radius increased, and with the turning radius equal to three times the wheel base, the wheel side loads were only about half of those at zero turning radius. The severity of the design loads for turning on the ground will therefore be considerably reduced if it can be ensured that the center of the minimum turning circle of the aircraft is a short distance outboard of either main undercarriage unit.

CONICAL FLOW AS A RESULT OF SHOCK AND BOUNDARY-LAYER INTERACTION ON A PROBE. J. Lukasiewicz. 1952. 16p. diagrs., photos. (ARC R & M 2669; ARC 12,023. Formerly RAE Tech. Note Aero 1968; SD 85)

The formation of a conical shock and a conical region of flow separation originating from the tip of a thin traversing tube was observed in a supersonic tunnel as a result of interaction of a strong shock with the boundary layer on the tube surface. The angles of the conical shock and separation surfaces and the static pressure in the separation region are in good agreement with the theoretical conical flow solutions. The extent of the conical flow illustrated should act as a warning against the use of static pressure tubes for measuring pressures in the regions of strong shocks.

Aeronautical Research Council (Gt. Brit.)
AN ELECTRIC TANK FOR THE DETERMINATION OF THEORETICAL VELOCITY DISTRIBUTIONS. T. J. Hargest. 1952. 9p. diagrs., photos. (ARC R & M 2699; ARC 12,448. Formerly NGTE Memo. M. 48)

An analogy due to Relf has been applied to the design of apparatus for quickly determining the theoretical velocity distributions around an airfoil in cascade. The accuracy of the apparatus was tested by determining the velocity distribution around a cylinder.

An accuracy of within 1 percent of the approach velocity was obtained for this case. The apparatus has since been applied to determine the theoretical velocity distribution around various airfoils in cascades; an example is given of the pressure distribution around an airfoil at zero incidence. An application to determine the theoretical velocity distribution around the central airfoil of a nozzle cascade where the effect of the ducting side walls is included is also given.

N-20671*

Aeronautical Research Council (Gt. Brit.)
VELOCITY DISTRIBUTION ON STRAIGHT AND SWEPT-BACK WINGS OF SMALL THICKNESS AND INFINITE ASPECT RATIO AT ZERO INCIDENCE. S. Newmark. 1952. 40p. diagrs. (ARC R & M 2713; ARC 10,907. Formerly RAE Aero 2200)

A solution by H. Ludwieg, giving the velocity distribution in the central section of a thin sweptback wing of infinite aspect ratio with a biconvex profile at zero incidence, has been found erroneous. In connection with this problem, the approximate method of sources and sinks for determining velocity distribution on straight and sweptback wings is critically examined, its limitations established, and proper ways of its application to three-dimensional problems indicated. A correct solution of Ludwieg's problem is found, and generalized to give the velocity distribution over the entire wing. The method is further extended to cover a wide class of thin symmetrical wing profiles, those with rounded leading edge being, however, often intractable by this particular method. The ultimate purpose of the investigation is to provide a reliable basis for determining the critical Mach number for sweptback wings. Further work is needed to embrace wings of finite aspect ratio and tapered wings, in particular, delta wings. The method seems adequate to deal with these more complex cases.

N-20672*

Aeronautical Research Council (Gt. Brit.)
THE NUMERICAL SOLUTION OF TWO-DIMENSIONAL FLUID MOTION IN THE NEIGHBOURHOOD OF STAGNATION POINTS AND SHARP CORNERS. L. C. Woods. 1952. 15p. diagrs. (ARC R & M 2726. Formerly ARC 12,887; FM 1407)

Methods are given in this paper of dealing with singularities of functions satisfying certain two-dimensional partial differential equations. For a numerical solution, the differential equations are replaced by difference equations on a square mesh. Log (1/q) where q is the velocity, becomes infinite at stagnation points, sharp corners, sinks, etc., while the conjugate function θ (flow direction) becomes multivalued. The method consists in finding a series expansion for the function (log 1/q or θ) in the neighborhood of the singularity. This expansion is then used to find relationships between the function values at points of the mesh adjacent to the singularity. A method of working directly in the transformed flow plane (in which the airfoil is a slit), and thus avoiding irregular squares on the boundary, is also given. The method is developed for incompressible flow, but an approximation suitable for compressible flow is given.

DECLASSIFIED NACA REPORTS

NACA RM A8E17

THE ASYMMETRIC ADJUSTABLE SUPERSONIC NOZZLE FOR WIND-TUNNEL APPLICATION. H. Julian Allen. July 23, 1948. 42p. diagrs., photos., 2 tabs. (NACA RM A8E17) (Declassified from Restricted, 10/30/52)

An asymmetric adjustable nozzle for supersonic wind tunnel application which permits continuous adjustment of the test-section Mach number is described. The characteristics of this nozzle are compared with the more conventional supersonic tunnel nozzles.

NACA RM L8E06

AERODYNAMIC CHARACTERISTICS AT HIGH SPEEDS OF RELATED FULL-SCALE PROPELLERS HAVING DIFFERENT BLADE-SECTION CAMBERS. Julian D. Maynard and Leland B. Salters, Jr. August 31, 1948. 54p. diagrs., tab., photo. (NACA RM L8E06) (Declassified from Restricted, 11/26/52)

Comparisons are made of results obtained in wind-tunnel tests of related full-scale propellers over a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour to evaluate the combined effects of blade-section camber and compressibility on propeller aerodynamic characteristics.

NACA RM L8E07

AERODYNAMIC CHARACTERISTICS AT HIGH SPEEDS OF FULL-SCALE PROPELLERS HAVING CLARK Y BLADE SECTIONS. Peter J. Johnson. October 26, 1948. 60p. diagrs., photos., tab. (NACA RM L8E07) (Declassified from Restricted, 11/26/52)

Results obtained in wind-tunnel tests of two full-scale propellers over a range of blade angles from 20° to 55° and at airspeeds varying from 60 to 485 miles per hour are presented.

NACA RM L8E24

AERODYNAMIC CHARACTERISTICS OF A TWO-BLADE NACA 10-(3)(08)-03R PROPELLER. Albert J. Evans and Leland B. Salters, Jr. September 2, 1948. 29p. diagrs., tab. (NACA RM L8E24) (Declassified from Restricted, 11/26/52)

Contains results of wind-tunnel tests on a full-scale NACA 10-(3)(08)-03R two-blade propeller. The

tests were part of a program to determine the effects of blade-shank design on propeller aerodynamic characteristics. A maximum efficiency of 91.5 percent was attained at a rotational speed of 1600 revolutions per minute at a 30° blade angle. Peak efficiency at a blade angle of 45° was decreased 32 percent by increasing the helical-tip Mach number from 0.80 to 1.20.

NACA RM L8H16

AERODYNAMIC CHARACTERISTICS OF A THREE-BLADE PROPELLER HAVING NACA 10-(3)(08)-03 BLADES. Robert E. Davidson. October 29, 1948. 29p. diagrs., tab. (NACA RM L8H16) (Declassified from Confidential, 11/26/52)

Contains results of wind-tunnel tests of a 10-foot-diameter, three-blade propeller at stream Mach numbers from 0.12 to 0.64. The tests were part of a program to determine the effects of blade number on propeller aerodynamic characteristics. The propeller blades are of designation NACA 10-(3)(08)-03. A maximum efficiency of 92 percent was attained at a rotational speed of 1350 rpm at a 40° blade angle. Peak efficiency at the design blade angle of 45° was decreased 4 percent by increasing the helical tip Mach number from 0.80 to 0.96.

NACA RM L9G20

TWO-DIMENSIONAL WIND-TUNNEL INVESTIGATION OF A 6-PERCENT-THICK SYMMETRICAL CIRCULAR-ARC AIRFOIL SECTION WITH LEADING-EDGE AND TRAILING-EDGE HIGH-LIFT DEVICES DEFLECTED IN COMBINATION. Robert J. Nuber and Gail A. Cheesman. September 6, 1949. 29p. diagrs., photo., 3 tabs. (NACA RM L9G20) (Declassified from Restricted, 10/7/52)

An investigation of a 6-percent-thick symmetrical circular-arc airfoil with leading-edge and trailing-edge high-lift devices was made to determine the effectiveness of these devices in increasing the maximum section lift coefficient of the airfoil when deflected in combination. The results indicated that, with the plain trailing-edge flap deflected 60°, maximum section lift coefficients of 2.02 and 1.95 can be obtained by deflecting a 15-percent-chord leading-edge slat or a 15-percent-chord drooped-nose flap, respectively. Variations in Reynolds number for either the slat or drooped-nose-flap configurations or moving the drooped-nose-flap hinge from the lower surface to the upper surface had essentially no effect on the lift characteristics.

CURRENT NACA REPORTS

NACA Rept. 1072

INELASTIC COLUMN BEHAVIOR. John E. Duberg and Thomas W. Wilder, III. 1952. iii, 16p. (NACA Rept. 1072. Formerly TN 2267)

This paper presents the significant findings of a theoretical study of column behavior in the plastic stress range that shows the tangent-modulus load to be the load at which bending can start for a straight column. Load-deflection analyses are made for two column models - one model having a concentrated flexibility and the other having its flexibility distributed along its length. Results are presented which relate the maximum load to the stress-strain curve of the material.

NACA Rept. 1079

SOUND FROM A TWO-BLADE PROPELLER AT SUPERSONIC TIP SPEEDS. Harvey H. Hubbard and Leslie W. Lassiter. 1952. ii, 9p. diagrs., photos. (NACA Rept. 1079. Formerly RM L51C27)

Propeller sound measurements at static conditions have been extended to a tip Mach number of 1.30. Spectrums have been obtained at both subsonic and supersonic tip speeds for comparison, and the measured data are compared with calculations by the Gutin theory. At supersonic tip speeds, the maximum intensities were measured in the plane of rotation and the spectrums are noted to contain a large high-frequency content. At supersonic tip speeds the over-all sound pressures, at a given power to the propeller, were noted to be independent of tip speed. The Gutin theory was found to be adequate for predicting the intensities of the lower-order harmonics but overestimates the intensities of the higher-order ones at supersonic tip speeds.

NACA Rept. 1084

COMPARISON OF HIGH-SPEED OPERATING CHARACTERISTICS OF SIZE 215 CYLINDRICAL-ROLLER BEARINGS AS DETERMINED IN TURBOJET ENGINE AND IN LABORATORY TEST RIG. E. Fred Macks and Zolton N. Nemeth. 1952. ii, 12p. diagrs., photos., tab. (NACA Rept. 1084. Formerly RM E51I05)

Inner- and outer-race cooling-correlation curves were obtained for the turbojet-engine turbine-roller bearing with the same inner- and outer-race cooling-correlation parameters and exponents as those determined for the test-rig bearing. The inner- and outer-race turbine roller-bearing temperatures may be predicted from a single curve regardless of variations in speed, load, oil flow, oil inlet temperatures, oil inlet viscosity, oil-jet diameter, or any combination of these parameters.

NACA TN 2892

A RAPID METHOD FOR ESTIMATING THE SEPARATION POINT OF A COMPRESSIBLE LAMINAR BOUNDARY LAYER. Laurence K. Loftin, Jr. and Homer B. Wilson, Jr. February 1953. 19p. diagrs. (NACA TN 2892)

A method which permits the rapid estimation of the separation point of a compressible laminar boundary layer has been developed. The method is generally applicable to any two-dimensional flow which satisfies the classical boundary-layer assumptions. Calculations made with the use of the method indicate that the amount of velocity recovery possible before laminar separation occurs decreases as the Mach number increases.

NACA TN 2893

THEORETICAL AND MEASURED ATTENUATION OF MUFFLERS AT ROOM TEMPERATURE WITHOUT FLOW, WITH COMMENTS ON ENGINE-EXHAUST MUFFLER DESIGN. Don D. Davis, Jr., George L. Stevens, Jr., Dewey Moore and George M. Stokes. February 1953. iii, 111p. diagrs., photos., 4 tabs. (NACA TN 2893)

Equations are presented for the attenuation characteristics of several types of mufflers. Experimental curves of attenuation plotted against frequency are presented for 77 different mufflers and the results are compared with theory. The experiments were made at room temperature without flow and the sound source was a loud-speaker. A method is given for including the tail pipe in the calculations. The application of the theory to the design of engine-exhaust mufflers is discussed, and charts have been included for the assistance of the designer.

NACA TN 2895

EFFECT OF VARIABLE VISCOSITY AND THERMAL CONDUCTIVITY ON HIGH-SPEED SLIP FLOW BETWEEN CONCENTRIC CYLINDERS. T. C. Lin and R. E. Street, University of Washington. February 1953. 122p. diagrs. (NACA TN 2895)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

The differential equations of slip flow, including the Burnett terms, were first solved by Schamberg assuming that the coefficients of viscosity and heat conduction of the gas were constants. The problem is solved herein for variable coefficients of viscosity and thermal conductivity by applying a transformation leading to an iteration method. The method, starting with the solution for constant coefficients, enables one to approximate the solution for variable coefficients very closely after one or two steps. Satisfactory results are shown to follow from Schamberg's solution by using his values of the constant coefficients multiplied by a constant factor η, leading to what are denoted as the effective coefficients of viscosity and thermal conductivity.

NACA TN 2897

EVALUATION OF GUST RESPONSE CHARACTERISTICS OF SOME EXISTING AIRCRAFT WITH WING BENDING FLEXIBILITY INCLUDED. Eldon E. Kordes and John C. Houbolt. February 1953. 31p. diagrs., 2 tabs. (NACA TN 2897)

Calculation studies made by means of the analysis presented in NACA TN 2763 to evaluate the influence that wing bending flexibility has on the structural response due to gust are reported for three twin-engine transports and one four-engine bomber. The manner in which dynamic response factors for acceleration and bending moment vary with various assumed operational factors is shown. Factors investigated include gust-gradient distance, gust shape, spanwise mass distribution, forward velocity, altitude, and compressibility and aspect-ratio corrections. A limited correlation of some of the calculated results with flight data is also presented.

NACA TN 2898

THEORETICAL CALCULATION OF THE PRESSURE DISTRIBUTION, SPAN LOADING, AND ROLLING MOMENT DUE TO SIDESLIP AT SUPERSONIC SPEEDS FOR THIN SWEPTBACK TAPERED WINGS WITH SUPERSONIC TRAILING EDGES AND WING TIPS PARALLEL TO THE AXIS OF WING SYMMETRY. Kenneth Margolis, Windsor L. Sherman and Margery E. Hannah. February 1953. 70p. diagrs., tab. (NACA TN 2898)

On the basis of linearized supersonic-flow theory, equations for the pressure distribution have been derived for thin, sweptback, tapered wings sideslipping at a constant angle of attack. The analysis is applicable to plan forms for which the wing tips are parallel to the axis of wing symmetry and at supersonic speeds for which the wing trailing edge is supersonic. A minor restriction is that the Mach cones emanating from the opposite side edges may not intersect on the wing. The plan form with both leading edges subsonic has been analyzed in detail. Equations for the span loading, rolling moment, and the corresponding stability derivative C_{l_β} have been obtained. Illustrative span loadings and variations of the derivative C_{l_β} with Mach number are presented for a number of wings.

NACA TN 2899

MEASUREMENTS OF FLYING QUALITIES OF AN F-47D-30 AIRPLANE TO DETERMINE LONGITUDINAL STABILITY AND CONTROL AND STALLING CHARACTERISTICS. Christopher C. Kraft, Jr., R. Fabian Goranson and John P. Reeder. February 1953. 75p. photos., diagrs., 2 tabs. (NACA TN 2899)

Flight tests were made of the flying qualities of an F-47D-30 airplane to determine the longitudinal stability and control and stalling characteristics.

NACA TN 2900

THE CALCULATION OF PRESSURE ON SLENDER AIRPLANES IN SUBSONIC AND SUPERSONIC FLO Max. A. Heaslet and Harvard Lomax. March 1953 25p. diagrs. (NACA TN 2900)

Under the assumption that a wing, body, or wing-body combination is slender or flying at near sonic velocity, expressions are given which permit the calculation of pressure in the immediate vicinity of the configuration. The disturbance field, in both subsonic and supersonic flight, is shown to consist of two-dimensional disturbance fields extending laterally and a longitudinal field that depends on the streamwise growth of cross-sectional area. A discussion is also given of couplings, between lifting and thickness effects, that necessarily arise as a result of the quadratic dependence of pressure on th induced velocity components.

NACA TN 2901

AN ANALYSIS OF THE FACTORS AFFECTING TH LOSS IN LIFT AND SHIFT IN AERODYNAMIC CENTER PRODUCED BY THE DISTORTION OF A SWEPT WING UNDER AERODYNAMIC LOAD. Charles W. Mathews and Max C. Kurbjun. March 1953. 65p. diagrs. (NACA TN 2901)

Results of a simplified analysis of the factors affec ing the loss in lift and shift in aerodynamic center o a swept wing due to its bending under aerodynamic load are presented as charts which relate the stres and aeroelastic effects considered to the wing struc tural weight, external geometry, material, and flight condition. Illustrative examples of the mag tudes of the aeroelastic effects to be expected are presented for typical swept wings. The manner in which these aeroelastic effects influence the longitu dinal stability of an airplane is also considered.

NACA TN 2906

AN AIRBORNE INDICATOR FOR MEASURING VERTICAL VELOCITY OF AIRPLANES AT WHEEL CONTACT. Robert C. Dreher. February 1953. 19p. diagrs., photos. (NACA TN 2906)

An investigation has been made with an airborne vertical-velocity indicator in order to determine the accuracy and practicability of such an indicator. A prototype installation was tested under controlled conditions in the Langley impact basin and by means of flight tests with a small trainer-type airplane. A second more compact installation which is retractable was developed for use on a high-speed jet bomber. A description of the operation of the indicator is given. The data obtained and an evaluation of the indicator are presented and show that this type of vertical-velocity indicator is accurate and practical for obtaining vertical velocities at the instant of airplane wheel contact.

NACA TN 2907

EFFECT OF HORIZONTAL-TAIL SPAN AND VERTICAL LOCATION ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT TAIL ASSEMBLY IN SIDESLIP. Donald R. Riley. February 1953. 39p. diagrs., photos., tab. (NACA TN 2907)

Wind-tunnel results on the effect of horizontal-tail span and vertical location of the horizontal tail relative to the vertical tail on the aerodynamic characteristics of an unswept vertical-tail assembly in sideslip are presented. By applying the well-known discrete-horseshoe-vortex method used for wings to the problem of intersecting surfaces, theoretical span loadings were obtained for each of the configurations tested. Calculated values obtained from the span loadings are compared with experimental results.

NACA TN 2909

STUDY OF SECONDARY-FLOW PATTERNS IN AN ANNULAR CASCADE OF TURBINE NOZZLE BLADES WITH VORTEX DESIGN. Harold E. Rohlik, Hubert W. Allen and Howard Z. Herzig. March 1953. 29p. diagrs., photos. (NACA TN 2909)

In order to increase understanding of the origin of losses in a turbine, the secondary-flow components in the boundary layers and the blade wakes of an annular cascade of turbine nozzle blades (vortex design) were investigated. A detailed study was made of the total-pressure contours and, particularly, of the inner-wall loss cores downstream of the blades. The inner-wall loss core associated with a blade of the turbine-nozzle cascade is largely the accumulation of low-momentum fluids originating elsewhere in the cascade. This accumulation is effected by the secondary-flow mechanism which acts to transport the low-momentum fluids across the channels on the walls and radially in the blade wakes and boundary layers. The patterns of secondary flow were determined by use of hydrogen sulfide traces, paint, flow fences, and total-pressure surveys. At one flow condition investigated, the radial transport of low-momentum fluid in the blade wake and on the suction surface near the trailing edge accounted for 65 percent of the loss core; 30 percent resulted from flow in the thickened boundary layer on the suction surface and 35 percent from flow in the blade wake.

NACA RM E52L05

PRELIMINARY COMPARISON OF 17- AND 75-MILLIMETER-BORE CAGELESS CYLINDRICAL ROLLER BEARINGS WITH CONVENTIONAL CYLINDRICAL ROLLER BEARINGS AT HIGH SPEEDS. E. Fred Macks, W. J. Anderson and Zolton N. Nemeth. March 1953. 39p. diagrs., photos., tab. (NACA RM E52L05)

Preliminary results at high speeds indicate lower bearing temperatures, less internal bearing wear, and greater reliability of the conventional, cage-type cylindrical roller bearings than of either full-complement or special cageless roller bearings of the types investigated, although the latter bearing types have been operated successfully to DN values of 1.0×10^6.

NACA RM E52L24a

SMOKE STUDIES OF SECONDARY FLOWS IN BENDS, TANDEM CASCADES, AND HIGH-TURNING CONFIGURATIONS. Arthur G. Hansen, Howard Z. Herzig and George R. Costello. March 1953. 33p. photos., diagr. (NACA RM E52L24a)

Flow-visualization studies, using smoke, were made of the secondary flows in rectangular bends, tandem cascades, and high-turning configurations. The roll-up of the wall boundary layer of a rectangular bend forms a passage vortex near the suction surface similar to that previously observed for cascades. The vortex so formed then shifts out into the main stream. Because of leading-edge effects, the boundary-layer flows in bends were found to be sufficiently different from the flows in blade rows to make direct application of bend results to blade rows inadvisable. Passage vortices are shown, in the tandem-cascade study, to resist turning with the main stream through which they pass and to disturb the flow in subsequent blade rows. This disturbance may explain in part the appreciable size of the losses sometimes attributed to secondary flows in turbomachines despite the fact that the energy involvement in vortex formation is slight. Tip-flow studies of high-turning blades with relative motion between blades and end wall indicated that if the relative sizes of the passage vortex forces, the tip clearance forces, and the blade-scraping effects are properly controlled, it may be possible to improve the blade-tip loading characteristics in turbomachine.

NACA RM E53A22

AN ANALYTICAL STUDY OF HEAT REQUIREMENTS FOR ICING PROTECTION OF RANDOMES. James P. Lewis. March 1953. 20p. diagrs. (NACA RM E53A22)

The heat requirements for the icing protection of two radome configurations have been studied over a range of design icing conditions. Both the protection limits of a typical thermal protection system and the relative effects of the various icing variables have been determined. For full evaporation of all impinging water, an effective heat density of 14 watts per square inch was required. When a combination of the full evaporation and running wet surface systems

square inch provided protection at severe icing and operating conditions.

Aeronautical Research Council (Gt. Brit.)
THE BOUNDARY LAYER WITH DISTRIBUTED SUCTION. M. R. Head. April 2, 1951. 118p. diagrs., photos., 4 tabs. (ARC 13,897; FM 1547; Perf. 771)

Experiments performed in flight at Reynolds numbers in the region of 3×10^6 have clearly demonstrated the stabilizing effect of small amounts of distributed suction on the laminar boundary layer. In the absence of a pressure gradient and in adverse gradients similar to those occurring on a normal airfoil, transition of the boundary layer to the turbulent form has been prevented by the use of such suction quantities as may be expected to lead to very considerable reductions in effective drag. It appears, however, that for extensive laminar flow to be achieved in this way, the surface must be free from such excrescences as would cause transition in the absence of suction. Laminar boundary-layer velocity profiles obtained with suction in the absence of a pressure gradient are found to be in good agreement with those calculated for the flat plate, and the suction quantities required to maintain laminar flow are similar to those suggested by stability theory.

Aeronautical Research Council (Gt. Brit.)
SOME PRELIMINARY RESULTS FROM V-G RECORDERS INSTALLED IN MILITARY AND CIVIL AIRCRAFT. R. Hain Taylor. 1952. 43p. diagrs., 5 tabs. (ARC R & M 2610; ARC 10,433. Formerly RAE SME 3393; RAE Tech. Note SME 188; ARC 7266; RAE Tech. Note SME 204; ARC 7475; RAE Tech. Note SME 232; ARC 7887; RAE Tech. Note SME 303; ARC 8621; RAE Tech. Note SME 368; ARC 9940)

During the latter half of the 1939-45 war, V-g recorder slides were collected from a number of operational and training aircraft types, and about April

mercial transport aircraft. A number of the results has been given limited circulation as Aeronautical Research Council papers, from heavy bombers in October 1943, from fighters in January 1944, and from twin-engined aircraft in April 1944, and a summary of readings from commercial aircraft in 1946; this report collects these scattered results into one body. Part I outlines the method of collection of the slides, describes the nature of the readings obtained, and their method of presentation, and discusses the results. These are grouped roughly into classes, as heavy bombers, fighters, twin-engined aircraft, training aircraft and commercial transport aircraft, and the possibilities of comparison between different types performing the same role, and between different roles performed by the same basic type, are indicated. Part II is a theoretical consideration of possible methods of analysis and extrapolation; it is pointed out that as the work has developed, first ideas have been enlarged or superseded, and finality is still far off. The advantages and disadvantages of several methods used up to 1946 are discussed, and suggestions are made for subsequent work.

INVESTIGATIONS ON SWEPT AND UNSWEPT WINGS AT HIGH SUBSONIC SPEEDS. J. Ackeret, M. Degen and N. Rott. February 16, 1951. 12p. diagrs. (ARC 13,788; FM 1525; Perf. 894)

In the high-speed wind tunnel of the Institue of Aerodynamics, E.T.H., Zürich, straight and sweptback wings have been tested at high subsonic speeds. Drag measurements at zero incidence were made on a series of geometrically similar models at the same Reynolds number, which was maintained constant by varying the air density. In this way the theoretical tunnel correction formulas could be checked and an extrapolation made to vanishing tunnel influence; straight and sweptback wings were compared after the corrections had been applied. Two different profile thicknesses (9 percent and 12 percent) were used. The transonic drag - Mach number relation for different thicknesses was found to be in very satisfactory agreement with von Kármán's similarity law.

NOTE ON THE EFFECT OF SWEEP AND INTERFERENCE ON THE OVERALL DRAG COEFFICIENT OF AN AIRCRAFT AT SUBCRITICAL MACH NUMBERS. J. H. Preston. March 22, 1951. 6p. (ARC 13,875; Perf. 769)

The influence of sweep and interference on the overall drag coefficient of an aircraft is discussed. It is concluded that the induced drag need only slightly exceed the ideal minimum for practical sweptback plan forms. The part of the profile drag coefficient independent of C_L may be slightly reduced by sweep, and the part proportional to C_L^2 may be considerably increased and may be sensitive to the spanwise variation of C_L from the mean value. The drag increments due to interference at junctions can be split into two parts - a profile loss such as would be obtained from a pitot traverse, and an induced loss arising from the secondary flows set up in the junction. This latter does not seem to have been studied in connection with aircraft. Both parts of the interference drag may rise steeply with increase of C_L. Correct design of the fairing and the use of boundary-layer suction would assist in reducing the interference drag.

DYNAMICALLY EQUIVALENT CIRCUITS OF TRANSDUCTORS FEEDING INDUCTIVE RESISTANCE LOADS. D. O. Burns. August, 1952. 26p. diagrs. (RAE Tech. Note EL. 41)

The dynamic relationship between the input voltage and the input current of series self-excited transductors has been reported on by various authorities, notably Milnes. However, amplifier designers in general, and servomechanics in particular, are more concerned with the dynamic relationship between input voltage and output current, especially when feeding inductive loads such as relays, motor windings, etc. In the case of the electronic amplifier, equivalent circuits, involving the parameters of the vacuum tube and the load resistance and inductance, which enable the dynamic response of the amplifier to be calculated, are now well known. As an extension of this field, this report gives the dynamically equivalent circuits for transductors, which may be used for calculating the dynamic responses of magnetic amplifiers feeding inductive resistance loads.

Marine Aircraft Experimental Establishment (Gt. Brit.) THE FULL SCALE HYDRODYNAMIC PERFORMANCE OF A LARGE FOUR-ENGINED FLYING BOAT AT OVERLOAD IN CALM WATER AND SWELL. J. A. Hamilton and R. V. Gigg. August 1952. 63p. diagrs., photos., 2 tabs. (MAEE F/Res/225)

Tests have been made on a large four-engined flying boat (Solent Mk. 3) to determine the hydrodynamic performance in sheltered water and in open sea swells. The results of general research interest are considered in this report. The sheltered water characteristics were investigated over a range of weights between 72,000 and 84,000 lb. The performance in swell covered weights up to 82,000 lb, and swell heights up to 5 feet.

THE EFFECT OF STOVE-ENAMELLING TEMPERATURES ON ALUMINIUM ALLOYS. G. Meikle and J. Thompson. August, 1952. 9p. diagrs. (RAE Tech. Note Met. 166)

The effect of heating the D.T.D. 603 type of alloy at 120°, 165° and 185° C was investigated as these temperatures are liable to be used either for stove-enamelling or for "curing" synthetic resin adhesives. Tests were also made at 120° C on D.T.D. 687 aluminum alloy. Stoving at 120° C is liable to cause a drop of 2 tons/sq in. in proof stress and ultimate tensile stress in D.T.D. 603 and this is not regained except by prolonged heating at 120° C. At 165° C, the improvement due to artificial aging is apparent after 2 hours heating. A temperature of 185° C for an hour is not likely to have much deleterious effect on fully aged D.T.D. 603 (D.T.D. 646) or D.T.D. 610 (D.T.D. 546). Heating D.T.D. 687 at 120° C for a few hours has only a slight deleterious effect.

Marine Aircraft Experimental Establishment (Gt. Brit.) 50 FT. REFUELLER MARK 2 NO. 2133 PERFORMANCE. November 1952. 14p. diagrs. (MAEE F/181, pt. 2)

Full performance measurements were made on 50-ft Refueller Mark 2, No. 2133, fitted with two Perkins S.6M. engines. The top speed of the craft fully laden is 10 knots, at a fuel consumption of 0.65 nautical m.p.g. The turning circle is about 2-1/4 boat lengths under most conditions, and the emergency stopping distance from full throttle also about 2-1/4 boat lengths. Fuel pumping rates are about the same as for the Mark 1 craft, that is, 20 gallons per minute per 1-1/2 in. hose. The fuel meter is, however, liable to give false indications of the quantity pumped, due to air entering the system. The fuel delivery rates of the craft are much lower than the rating of the pump. The compressed air starting system is barely adequate. Higher pressure cylinders and a larger compressor are desirable.

N-21036*

Marine Aircraft Experimental Establishment (Gt. Brit.) PRELIMINARY PRESSURE MEASUREMENTS DURING THE LANDING OF A SUNDERLAND MARK 5 FLYING BOAT IN ROUGH WATER CONDITIONS INCLUDING ONE ON WHICH THE FOREBODY WAS SEVERELY DAMAGED. R. Parker. Appendix I by W. McClymont. Appendix II by R. Parker. September 1952. 40p. diagrs., photos., 5 tabs. (MAEE F/Res/227)

A series of 11 exploratory landings were carried out on a Sunderland Mark 5 flying boat in rough water conditions, during which pressures at various positions on the planing bottom and the c.g. acceleration were measured. Detailed investigations were to be carried out, based on these tests, but the aircraft was severely damaged and this report presents these first results. Analysis of these results shows that pressures occurring in the bow region are of the same order of magnitude as those in the main step region which, in turn, are similar in magnitude to those encountered in high rate of descent landings in calm water conditions. Pressures recorded on the afterbody are invariably much lower than those on the forebody. The greatest risk of damaging the aircraft occurs when, a short time after touchdown, the aircraft still has considerable forward speed and the pilot little or no control.

STRESS CORROSION IN AIRCRAFT ALLOYS. Joseph B. McAndrew and Howard T. Francis. (Final rept.) May 29, 1952. i, 24p. photos. (Armour Research Foundation)

An attempt has been made to verify the existing theory for the stress corrosion cracking of aluminum 4-percent copper alloy. The approach used has employed a scanning device, called a "corroscope," which permits a two-dimensional picture to be observed on an oscilloscope, in which is shown the potential distribution in the electrolyte immediately adjacent to the corroding metal surface. Since this potential field is directly related to the current lines flowing from point to point on the specimen, the picture allows direct observation of the location of anodic and cathodic regions on the surface.

THE PLASTIC DEFORMATION OF SINGLE CRYSTALS OF ALUMINUM. R. D. Johnson, A. P. Young, W. B. Wilson and A. D. Schwope. (Summary rept.) October 10, 1952. i, 59p. photos., diagrs., tab. (Battelle Memorial Inst.)

This report describes a portion of the work performed in a fundamental investigation of creep in metals. The creep of single crystals of high-purity aluminum has been studied in the temperature range from 700° F to 1100° F. Experiments were carried out to investigate the possible effect of small amounts of prestraining by various methods on the creep properties of these aluminum single crystals. An experimental survey was conducted with various high-resolution X-ray diffraction techniques to determine the feasibility of studying the nature of plastic deformation in this manner.

NACA TN 2867

HEAT AND MOMENTUM TRANSFER BETWEEN A SPHERICAL PARTICLE AND AIR STREAMS. Y. S. Tang, J. M. Duncan and H. E. Schweyer, University of Florida. March 1953. 48p. diagrs., photo., tab. (NACA TN 2867)

Heat-transfer coefficients for a spherical particle heated by an induction coil in a moving air stream were experimentally determined for the Reynolds number range from 50 to 1000 using spheres of 1/8- to 5/8-inch diameter and air velocities from 1 to 13 feet per second. A correlation of the heat-transfer factor or Stanton number with the Reynolds number was obtained and expressed by an empirical equation. This correlation is in agreement with the values calculated from theory for the lower range of Reynolds numbers studied. The skin-friction factor representing the momentum transfer calculated from the boundary-layer theory shows good agreement with the experimental heat-transfer factor except in the lower range of Reynolds numbers studied. The relationship $St = C_f/2$ where St is the Stanton number and C_f is the skin-friction factor is suggested for the case of an air stream flowing around a sphere. An empirical equation relating the heat-transfer factor to the total-drag coefficient is also suggested.

NACA TN 2890

A LINEAR TIME-TEMPERATURE RELATION FOR EXTRAPOLATION OF CREEP AND STRESS-RUPTURE DATA. S. S. Manson and A. M. Haferd. March 1953. 49p. diagrs. (NACA TN 2890)

A time-temperature parameter based on examination of the published stress-rupture data for a variety of materials is proposed in the form $(T - T_a)/(\log t - \log t_a)$, where T is temperature in degrees Fahrenheit, t is rupture time or the time to obtain a given total creep elongation, and T_a and $\log t_a$ are material constants which appear to be determinable from suitable rupture data in the time range between 30 and 300 hours. For the 40 materials investigated, use of this parameter in conjunction with experimental data involving rupture times below 300 hours resulted in very good extrapolations to longer rupture times (up to 10,000 hr where data were available) compared with corresponding predictions obtainable from a recently proposed parameter $(T + 460)(20 + \log t)$. For correlation of minimum creep-rate data, the parameter used is in the form $(T - T_a)/(\log r + \log r_a)$, where r is the creep rate and r_a is a material constant.

NACA TN 2902

MATRIX METHODS FOR DETERMINING THE LONGITUDINAL-STABILITY DERIVATIVES OF AN AIRPLANE FROM TRANSIENT FLIGHT DATA. James J. Donegan. March 1953. 65p. diagrs., 6 tabs. (NACA TN 2902)

Three methods are presented for calculating the longitudinal stability derivatives from transient flight data. Several examples using flight data are given to illustrate the method. The results indicate the scatter which is typical of this type of analysis.

NACA TN 2903

IMPINGEMENT OF CLOUD DROPLETS ON AERODYNAMIC BODIES AS AFFECTED BY COMPRESSIBILITY OF AIR FLOW AROUND THE BODY. Rinaldo J. Brun, John S. Serafini and Helen M. Gallagher. March 1953. 20p. diagrs. (NACA TN 2903)

The trajectories of water droplets in a compressible-air flow field around a cylinder were computed with a mechanical analog. The results of the calculations at the flight critical Mach number were compared with calculations of trajectories in an incompressible flow field. For a cylinder, the effect of compressibility of the air on the droplet trajectories was negligible up to the flight critical Mach number. The results obtained with the cylinder were extended to airfoils. This extension is possible because the incompressible flow fields of both cylinders and airfoils are similarly altered by compressibility.

NACA TN 2904

IMPINGEMENT OF WATER DROPLETS ON A CYLINDER IN AN INCOMPRESSIBLE FLOW FIELD AND EVALUATION OF ROTATING MULTICYLINDER METHOD FOR MEASUREMENT OF DROPLET-SIZE DISTRIBUTION, VOLUME-MEDIAN DROPLET SIZE, AND LIQUID-WATER CONTENT IN CLOUDS. Rinaldo J. Brun and Harry W. Mergler. March 1953. 71p. diagrs., photo., 4 tabs. (NACA TN 2904)

The trajectories of water droplets in an incompressible flow field around a cylinder were calculated with a mechanical analog. The collection efficiency, the area of droplet impingement on the cylinder, and the rate of droplet impingement were determined from the trajectories. An evaluation of the rotating multicylinder method for the measurement of droplet-size distribution, volume-median droplet size, and liquid-water content was made based on the results of the trajectory calculations.

NACA TN 2910

AN APPLICATION OF THE METHOD OF CHARACTERISTICS TO TWO-DIMENSIONAL TRANSONIC FLOWS WITH DETACHED SHOCK WAVES. Keith C. Harder and E. B. Klunker. March 1953. 16p. diagrs. (NACA TN 2910)

An application of the method of characteristics is presented which affords a means for determining the surface pressures for a class of two-dimensional airfoils of given nose shape and arbitrary rear part in a sonic or supersonic stream if surface pressure data are given for one member of the class. For engineering purposes, the method of characteristics may be replaced by a simple application of Prandtl-Meyer flow concepts. An explanation of the nonlinear force characteristics of two-dimensional airfoils at transonic speeds is presented on the basis of sensitivity of these flows to changes in geometry and angle of attack.

NACA TN 2911

A LOW-SPEED EXPERIMENTAL STUDY OF THE DIRECTIONAL CHARACTERISTICS OF A SHARP-NOSED FUSELAGE THROUGH A LARGE ANGLE-OF-ATTACK RANGE AT ZERO ANGLE OF SIDESLIP. William Letko. March 1953. 27p. diagrs., photo. (NACA TN 2911. Formerly RM L52J14)

Static yawing moments and some instantaneous yawing moments are presented through a range of angle of attack at zero sideslip angle for a plain fuselage model having a sharp conical nose and for the fuselage with several nose modifications, one of which consisted of a ring located at different stations along the nose. Some circumferential pressure measurements at one station on the body at several angles of attack are also presented.

NACA TN 2912

THE NORMAL COMPONENT OF THE INDUCED VELOCITY IN THE VICINITY OF A LIFTING ROTOR AND SOME EXAMPLES OF ITS APPLICATION. Walter Castles, Jr. and Jacob Henri De Leeuw, Georgia Institute of Technology. March 1953. 38p. diagrs., 3 tabs. (NACA TN 2912)

A method is presented for computing the approximate values of the normal component of the induced velocity at points in the flow field of a lifting rotor. Tables and graphs of the relative magnitudes of the normal component of the induced velocity are given for selected points in the longitudinal plane of symmetry of the rotor and on the lateral rotor axis. A method is also presented for using the tables and graphs to determine the interference induced velocities arising from the second rotor of a tandem- or side-by-side-rotor helicopter and the induced flow angle at a horizontal tail plane.

NACA TN 2913

ON THE DEVELOPMENT OF TURBULENT WAKES FROM VORTEX STREETS. Anatol Roshko, California Institute of Technology. March 1953. 77p. diagrs., photos., 3 tabs. (NACA TN 2913)

Wake development behind circular cylinders at Reynolds numbers from 40 to 10,000 was investigated by hot-wire techniques in a low-speed wind tunnel. The Reynolds number range of periodic vortex shedding is divided into two distinct subranges. In the stable range, R = 40 to 150, regular vortex streets are formed and no turbulent motion develops, the vortices decaying by viscous diffusion. The range R = 150 to 300 is a transition region to the irregular range in which turbulent velocity fluctuations accompany the periodic formation of vortices. The diffusion is turbulent and the wake becomes fully turbulent in 40 to 50 diameters. The turbulence is initiated by laminar-turbulent transition in the free layers which spring from the separation points on the cylinder. An annular vortex street was observed in the wake of a ring.

NACA TN 2914

A METHOD FOR RAPID DETERMINATION OF THE ICING LIMIT OF A BODY IN TERMS OF THE STREAM CONDITIONS. Edmund E. Callaghan and John S. Serafini. March 1953. 33p. diagrs. (NACA TN 2914)

The effects of existing frictional heating were analyzed to determine the conditions under which ice formations on aircraft surfaces can be prevented. A method is presented for rapidly determining by means of charts the combination of Mach number, altitude, and stream temperature which will maintain an ice-free surface in an icing cloud. The method can be applied to both subsonic and supersonic flow. The charts presented are for Mach numbers up to 1.8 and pressure altitudes from sea level to 45,000 feet.

NACA TN 2915

EFFECT OF PROCESSING VARIABLES ON THE TRANSITION TEMPERATURE, STRENGTH, AND DUCTILITY OF HIGH-PURITY, SINTERED, WROUGHT MOLYBDENUM METAL. Kenneth C. Dike and Roger A. Long. March 1953. 26p. diagrs., photos., 3 tabs. (NACA TN 2915)

High-purity, sintered, wrought molybdenum metal has a transition temperature range near room temperature which varies according to the amount of swaging reduction; increasing swaging reduction decreases the transition temperature range. Recrystallized metal possesses a higher transition temperature range than as-swaged metal, regardless of the amount of prior working. Ultimate tensile strengths of as-swaged, stress-relieved, or recrystallized metal are affected by varying amounts of working from 35 to 99 percent swaging reduction, but the differential is not large. Ductility of as-swaged metal at room temperature increases with increased working; however, when stress-relieved, the ductility does not vary with working. Recrystallized metal has good ductility above the transition range

provided that the prior working is greater than about 50 percent. Other data are presented as to grain size, type of fracture, and chemical analysis.

NACA TN 2917

A MODIFIED REYNOLDS ANALOGY FOR THE COMPRESSIBLE TURBULENT BOUNDARY LAYER ON A FLAT PLATE. Morris W. Rubesin. March 1953. 23p. diagrs., tab. (NACA TN 2917)

A modified Reynolds analogy is developed for the compressible turbulent boundary layer on a flat plate. When mixing-length theories are used to evaluate terms of the final expressions, it is found for air that the ratio of Stanton number to half the local skin-friction coefficient is greater than unity. At Mach number equals zero, this ratio is of the order of 1.18 to 1.21 for Reynolds numbers based on momentum thickness of 10^3 to 10^6. Up to a Mach number of 5 and under extreme conditions of surface temperature, it is found that the ratio of Stanton number to half the skin-friction coefficient differs from its values for the incompressible case (M = 0) by amounts so small as to be of the magnitude of the uncertainties in the theory.

NACA TN 2918

EFFECTS OF PARALLEL-JET MIXING ON DOWNSTREAM MACH NUMBER AND STAGNATION PRESSURE WITH APPLICATION TO ENGINE TESTING IN SUPERSONIC TUNNELS. Harry Bernstein. March 1953. 26p. diagrs., photos. (NACA TN 2918)

A one-dimensional analysis of the results of the parallel-jet mixing encountered in the testing of engines in supersonic wind tunnels is reported. This type of analysis presents a reasonable approach to obtaining approximate figures for the tunnel operating conditions while the tunnel is still in the design stage. These figures would be based upon the known tunnel geometry and inlet conditions and estimations of the model geometry and values of the engine performance parameters. Additional equations are presented for evaluation of changes due to the burning of excess fuel downstream of the engine-exhaust station.

NACA TM 1355

STUDY OF THE SUPERSONIC PROPELLER. (Étude de L'Hélice Supersonique). Jean Fabri and Raymond Siestrunck. March 1953. 23p. diagrs. (NACA TM 1355. Trans. from Ministère de l'Air. Publications Scientifiques et Techniques 248, 1951, p. 113-130; International Conference on Mechanics, Proceedings, v. 1, 1950).

In this paper a propeller having all sections operating at supersonic speeds is designated a supersonic propeller regardless of flight speed. Analyses assume subsonic flight speeds but very high rotational speeds. A very elementary analysis of the efficiency of a jet-propeller system is presented. A propeller analysis based on conventional vortex blade element theory is presented and reduced to a single point method which leads to an expression for optimum advance ratio in terms of hub-tip diameter ratio and airfoil fineness ratio. An expression for propeller efficiency in terms of advance ratio, hub-tip diameter ratio, and airfoil thickness ratio is also presented. Use is made of theoretical airfoil characteristics at supersonic speeds. A study of blade section interference, blade shock and expansion fields, at supersonic section speeds is presented. An example taken indicates that an efficiency of seventy percent can be obtained with a propeller having a tip Mach number of 2.3.

THE CALCULATION OF AERODYNAMIC DERIVATIVE COEFFICIENTS FOR WINGS OF ANY PLAN FORM IN NON-UNIFORM MOTION. W. P. Jones. 1952. 12p. diagrs., tab. (ARC R & M 2470. Formerly ARC 10, 142; 0. 623; FM 1030; S & C 2074)

In the present paper, a method is outlined for the calculation of aerodynamic forces on wings of any plan form in steady or unsteady motion. It is based on vortex sheet theory for thin wings as developed by the writer in previous reports, but makes use of Falkner's scheme for the approximate calculation of downwash distributions. In the earlier work, satisfactory agreement with the experimental evidence available was obtained, but as the downwash distributions were calculated exactly the numerical work was rather complicated and involved the use of incomplete elliptic integrals and the treatment of singularities. The method now proposed avoids these computational difficulties and is perhaps more suitable for routine calculations of flutter derivatives. Satisfactory solutions of many problems in steady motion have already been obtained by Falkner using approximate downwash distributions as determined by his vortex lattice, and it is thought that the similar scheme suggested in this paper might also prove to be sufficiently accurate for problems in unsteady motion. The computational procedure is briefly summarized

in appendix II. Certain modifications of the main scheme which would further reduce the amount of computation are indicated in the main text.

Aeronautical Research Council (Gt. Brit.)
FLIGHT TESTS ON HURRICANE II, Z.3687 FITTED WITH SPECIAL WINGS OF 'LOW-DRAG' DESIGN. R. H. Plascott, D. J. Higton, F. Smith and A. R. Bramwell. 1952. 13p. diagrs. (ARC R & M 2546; ARC 9172; ARC 10,106. Formerly RAE Aero 2090; Aero 2153)

This report describes flight tests to investigate the profile-drag characteristics of a "low-drag" section wing built by Armstrong Whitworth, Ltd., using a new type of construction of their own design. During the first series of tests, a section of the wing was pressure-plotted and the results showed that it should be possible to obtain laminar flow over a range of lift coefficient from 0.12 to 0.50. A few preliminary profile-drag measurements were also made and a fairly low profile-drag coefficient (C_D = 0.0046 to 0.0050) was recorded over a lift coefficient range of 0.20 to 0.40; there was, however, a rapid rise in the profile drag coefficient at lift coefficients less than 0.20, and investigation of the surface waviness showed that the failure to maintain laminar flow at higher speeds was probably due to the excessive waviness present, which amounted to a variation of about ±2-1/2 thousandths of an inch from the mean deflection curve on a two-inch gage length. A further series of profile-drag measurements was made when the surface waviness had been reduced to ±1 thousandth of an inch variation from the mean deflection curve on a 2-inch gage length. It was found that, provided no flies or other insects were picked up during the flight, the drag coefficient had been reduced to 0.0044 over a range of lift coefficient from 0.12 to 0.50. This corresponds to transition from 50 to 60 percent chord. With the reduced surface waviness, it was possible to maintain laminar flow up to Reynolds numbers of nearly 20 millions.

TESTS IN THE COMPRESSED AIR TUNNEL ON THE AEROFOILS NACA 0015 AND NACA 0030 WITH AND WITHOUT SPLIT FLAP AND ON OTHER AEROFOILS OF VARIOUS THICKNESSES WITH A SPLIT FLAP. R. Jones. 1952. 32p. diagrs., 16 tabs. (ARC R & M 2584. Formerly ARC 4191; ARC 4511; ARC 4607)

This report contains the results of experiments to determine the effect of thickness on the aerodynamic characteristics of a group of rectangular wings with and without a split flap. Wings with the following airfoil sections were tested: NACA 0015 and NACA 0030 with and without a split flap; NACA 0012, NACA 23012, RAF 28 and RAF 48 with the flap. The effect of rounding the edge of the flap was considered on the wing with NACA 0015 section. The effect of rounding the ends of the NACA 0030 section was examined. C_L, C_D, and C_m were obtained over a range of Reynolds numbers with additional C_D measurements at closer intervals of R on the two wings without flap.

THE EFFICIENCY OF A PITOT INTAKE INCLINED TO THE AIR STREAM. E. L. Place and R. Lecavalier. 1952. 8p. diagrs. (ARC R & M 2621; ARC 11,162. Formerly NGTE Memo. M. 21)

In an earlier report on intake ducting for supersonic flight, the efficiency of a "pitot" type intake was discussed and shown to have a marked effect on the performance of gas-turbine engines. The present report is supplementary in that it describes the effect of inclining the pitot intake to the main airstream direction in the transonic Mach number range 0.7 to 1.5, an effect which is at present incalculable. Curves are presented showing the influence of inclination on intake adiabatic efficiency and air mass flow into the intake. These experimental results are then illustrated by application to the performance of a typical turbine engine and a propulsive duct in sonic and supersonic flight. At a flight Mach number of 1.5, it is found that, for both turbine engine and propulsive duct, an inclination of 5° reduces the net thrust by roughly 2 percent compared with the normal flight thrust. For inclinations greater than 5°, however, thrust falls off more rapidly, and at 10° inclination, it is reduced by roughly 6.5 percent for the turbine engine and 7.5 for the propulsive duct.

REGENERATOR HEAT EXCHANGERS FOR GAS-TURBINES. J. E. Johnson. 1952. 72p. diagrs., 13 tabs. (ARC R & M 2630; ARC 11,770. Formerly RAE Aero 2266; SD 27)

Information was required from which the performance of regenerators suitable for heat exchangers for gas turbines could readily be estimated. A series of

tables and curves have been prepared from which the efficiency of a regenerator can be calculated if the operating conditions and heat-transfer coefficients are known. The tables and curves cover a range of lengths and blow times appropriate to gas-turbine conditions. Measurements of heat transfer and pressure drop coefficients have been made on several examples of matrix of both the gauze and flame trap type in conditions similar to those in a gas turbine. A number of examples have been worked out from the experimental results to show the relative importance of the different variables on the performance of typical regenerators. A gauze matrix of fine wire and open mesh has a much lower weight and only slightly higher pressure drop than a flame-trap matrix for the same efficiency. The recommended size of gauze is a wire diameter of 0.002 in. to 0.004 in. and a mesh of 20 to 40 wires per inch; the material should be stainless steel. Further design study is necessary to determine whether this advantage can be maintained in a complete regenerator.

COMPARATIVE FLUTTER TESTS ON TWO, THREE, FOUR AND FIVE-BLADE PROPELLERS. H. G. Ewing, J. Kettlewell and D. R. Gaukroger. 1952. 8p. diagrs. (ARC R & M 2634; ARC 11,438. Formerly RAE Structures 18)

This report describes comparative flutter tests on two-, three-, four-, and five-blade Duralumin propellers with the same blade design. The tests were made on the No. 3 spinning tower, Royal Aircraft Establishment. Strain gages were used for determining the vibratory stresses and the phase relations between the blades. A wide range of blade angles above and below the stalling region was explored. Stalling flutter was the only form encountered. The phase relation of the blades was found to be dependent on number of blades and speed of rotation, and to influence the amplitude of the vibratory stresses. It is shown that no direct comparison of the flutter characteristics of the two-, three-, four-, and five-blade propellers can be made.

CONCERNING THE ANNULAR AIR INTAKE IN SUPERSONIC FLIGHT. I. M. Davidson and L. E. Umney. 1952. 22p. diagrs., photos. (ARC R & M 2651; ARC 11,645. Formerly NGTE R. 16)

The stability of an annular air intake at a Mach number of 1.4 and with Reynolds numbers of about 1.5×10^6 is considered in detail and a method is described whereby the experimental results might be extrapolated for preliminary full-scale design purposes. This extrapolation has yet to be checked experimentally, but suggests that a typical aircraft intake would have an over-all isentropic efficiency of about 85 percent. The results also indicate that both the stability and the efficiency of an intake could be improved by controlling the boundary layer on its nacelle, and as an alternative to boundary-layer suction a device which is described as a segregation ring is suggested. This, it appears, might raise the efficiency by some 2 or 3 percent.

THE PHYSICAL CHARACTERISTICS OF WIRE RESISTANCE STRAIN GAUGES. Eric Jones and K. R. Maslen. 1952. 44p. diagrs., photos., 4 tabs. (ARC R & M 2661; ARC 12,357. Formerly RAE Instn. 2)

This report deals with the fundamental principles of the wire resistance strain gage. Types of strain gage in common use and their methods of construction are described, and the mechanism whereby strain effects change of resistance is discussed. A subsection is devoted to the behavior of fine wires, in general, under strain. Possible causes of error, including the effects of humidity and temperature, are discussed, and as far as possible methods are given of overcoming these difficulties. The effect of the passage of current on the strain gages is described, and methods of increasing the output are suggested. The final section is devoted to miscellaneous properties of the wire resistance strain gage, on several of which very little information is at present available.

THEORETICAL INVESTIGATIONS OF TERNARY LIFTING SURFACE - CONTROL SURFACE - TRIMMING TAB FLUTTER AND DERIVATION OF A FLUTTER CRITERION. H. Wittmeyer. 1952. 42p. diagrs., 3 tabs. (ARC R &M 2671; ARC 12,043. Formerly RAE Structures 19)

Theoretical investigations have been made of the flutter of an idealized trimming tab system having three degrees of freedom - normal translation of the main lifting surface, rotation of the control surface, and rotation of the tab. All the structural parameters of the system have been varied except the out-of-balance moment of the control surface. The cases in which the system is free from flutter have been particularly investigated. From these investigations, criteria for the avoidance of flutter have been derived. If the structural parameters of the system satisfy these criteria, flutter of the system with these three degrees of freedom should be impossible. The results are applicable to trimming tabs, servotabs with zero follow-up ratio, and generally to all systems in which the tab can be regarded as connected elastically only to the control surface.

FLOW THROUGH A HELICOPTER ROTOR IN VERTICAL DESCENT. P. Brotherhood. 1952. 14p. diagrs., photos. (ARC R & M 2735; ARC 11,837. Formerly RAE Aero 2272)

Flight tests have been made on a Hoverfly I helicopter to investigate the types of flow associated with various rates of vertical descent. At the same time, measurements of the performance were made. The results are analyzed by two different methods to produce characteristic curves for the rotor and are compared with data obtained from wind-tunnel tests on model propellers at negative rates of advance. The information was obtained from the Hoverfly I helicopter but it is thought that the results can be applied to any other helicopter of similar size.

LOW-SPEED WIND-TUNNEL TESTS OF FOWLER FLAPS, SLATS AND NOSE FLAPS ON A MODEL OF A JET AIRCRAFT WITH A 40 DEG SWEPT-BACK WING. A. Spence. 1952. 18p. diagrs., 6 tabs. (ARC R & M 2752; ARC 12, 131. Formerly RAE Aero 2302)

This report presents the results of tests with Fowler flaps on a model of a single-jet aircraft with a 40° sweptback 10-percent-thick wing. Slats and nose flaps were also tested as means of delaying the tip stall. The maximum trimmed lift coefficient without flaps or slats was 1.055 ($R = 2.7 \times 10^{6}$). With half-span Fowler flaps (leaving a gap across the fuselage) and slats over the outer half of the span, this value was increased to 1.64, and there was adequate stability. Tests in which the spanwise extent of the nose flap was varied, indicated that about 50 percent wing semispan per side was the optimum length of slat or nose flap for avoiding instability at the stall.

Aeronautical Research Council (Gt. Brit.)
NOTE ON THE INFLUENCE OF ASPECT RATIO ON THE VARIATION WITH MACH NUMBER OF THE LIFT AND HINGE-MOMENT CHARACTERISTICS OF A WING AND FULL-SPAN CONTROL. A. D. Young and P. R. Owen. 1952. 6p. diagr., tab. (ARC R & M 2767; ARC 7046; ARC 7133. Formerly RAE Tech. Note Aero 1250; RAE Tech. Note Aero 1263)

It is shown on the basis of the linearized theory that the effects of compressibility on the lift and hinge-moment characteristics of a wing and full-span control are functions of aspect ratio. With reduction in aspect ratio, the increase of the lift characteristics with Mach number is reduced appreciably. The same effect is noted for the hinge-moment characteristic b_1. The effects on the hinge-moment characteristics b_2 and b_3 are rather more complicated, but in many practical cases the influence of aspect ratio will be very small.

THE YOUNG'S MODULUS, POISSON'S RATIO AND RIGIDITY MODULUS OF SOME ALUMINIUM ALLOYS. PART II. N. Dudzinski. November 1952. 28p. photos., 14 tabs. (RAE Met. 69)

Various binary and ternary chill-cast or sintered aluminium alloys were prepared and their elastic properties investigated. It was found that the nitrides of aluminium, chromium, magnesium, iron, vanadium, titanium, and zirconium caused an appreciable increase in Young's modulus. Ternary intermetallic compounds showed a similar effect. The specific Young's modulus value was improved by the additions of chromium or manganese. The rigidity modulus value in torsion was similar to that calculated from E and Poisson's ratio. The effect of composition and the heat of formation of various intermetallic compounds is discussed.

ALUMINIUM-COPPER-CADMIUM SHEET ALLOYS. H. K. Hardy. May 22, 1952. 25p. diagrs., photos., 13 tabs. (MOS S & TM 9/52; Fulmer Research Institute Ltd.)

Aluminum-copper-cadmium alloys have been rolled to sheet on a semitechnical scale and showed an exceptional capacity for hot work. The aging characteristics have been examined and an uncoated alloy with 5 percent copper-0.15 percent cadmium gave 25 tons/sq in. for the 0.1 percent proof stress and 30 tons/sq in. maximum stress in both the transverse and longitudinal directions. Cold working prior to artificial aging markedly raised the tensile properties of aluminum-copper alloys but had the unique effect of reducing the properties of the aluminum-copper-cadmium alloys. The proof stress can drop by 3 tons/sq in. but the effect can be prevented if the alloy is given a short partial aging ("incubation") treatment at 165° or 170° C before cold working. Aluminum-copper alloys showed a marked susceptibility to stress corrosion resulting from severe intercrystalline corrosion. Aluminum-copper-cadmium alloys were immune from stress corrosion and showed an intracrystalline attack when sprayed with 3 percent sodium chloride solution.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) AN INVESTIGATION INTO THE PITOT RAKE METHOD OF MEASURING TURBO JET ENGINE THRUST IN FLIGHT. J. Stephenson, R. T. Shields and D. W. Bottle. December 23, 1952. 56p. diagrs., 9 tabs. (AAEE/Res/265)

Tests have been made to establish whether a pitot rake could be used as an absolute measure of the thrust of a jet engine on the ground and in flight. The tests were made to investigate errors due to the assumptions inherent in the single pitot method of estimating thrust in flight, and to establish if a rake can be used to calibrate the single pitot of an uncalibrated engine installed in an aircraft. The tests were also planned to check the generally accepted nondimensional thrust relationship for jet engines. The tests were made on Derwent 5 engines installed in Meteor 4 aircraft. The tests covered a wide range of flight conditions and included test bed

measurements on bare engines and later, measurements of exit static pressure. Although the tests could not all be made on the same engine, the same final nozzle was used in all the main tests. The main conclusions were: (1) Static tubes must be incorporated in the pitot rake to give absolute thrust measurements and even so a discrepancy of 2 percent requires further investigation. (2) The single pitot method of estimating flight thrust based on engine test bed calibration was in error by as much as 6 percent due to changes in total pressure sampled by the single pitot and in the magnitude of the exit static pressure between calibration and test conditions. Using the pitot static rake to calibrate the single pitot of an installed engine introduced flight thrust errors no larger and possible smaller. (3) Nondimensional thrusts at 35,000 ft were some 7 percent lower than corresponding thrusts at 5,000 ft. Further tests are required to establish the magnitude of these effects on other engine types.

EFFECT OF THE CONTROL-CIRCUIT ON FLUTTER. (Einfluss der rudersteürung auf das flattern). K. Leiss. June 17, 1948. 50p. diagrs. (ARC 11,583; 0.734. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. FB 1670, October 10, 1942)

As a result of the participation of the controls, the following types of flutter appear: when the control is slack there is flutter of the system with the control organ and the control surface out of phase, but when the control is stiff there is flutter with the two components in phase. The second type of flutter, in particular, has only been treated incompletely, if at all, up to the present; but because of its appearance the advantage of stiffening the control is doubtful. Mass-balancing of the control surface, and - with occasional exceptions - structural damping in the control system, improve the flutter properties, especially when the control organ and the control surface are in phase with each other. The oscillation of the controls is included in the flutter calculations by means of suitable transformations; this is done in such a way that little more computational work is involved than for the case where the oscillation of the control system is neglected.

National Gas Turbine Establishment (Gt. Brit.)
THE BURNING OF SINGLE DROPS OF FUEL. PART III. COMPARISON OF EXPERIMENTAL AND THEORETICAL BURNING RATES AND DISCUSSION OF THE MECHANISM OF THE COMBUSTION PROCESS. G. A. E. Godsave. August 1952. 47p. diagrs., photos. (NGTE R.88)

A theoretical and experimental investigation has been made of the factors influencing the rate of decrease in size of a single burning drop, as in a burning fuel spray. The experimental technique adopted in this investigation has been to suspend a single drop of fuel on a fine silica filament, and to measure with a cinematograph camera the rate of decrease in size during combustion in still air. A theoretical treatment given in part I indicates that the heat transfer to the drop is the dominant factor determining its life. The coefficient of heat transfer to the drop is itself a function of the mass evaporation rate. The analysis given enables a solution to be obtained for the heat transfer to the drop in the presence of the evaporative flow of the vapor. The experimental results presented in part II have been examined here in part III on the basis of such a heat-transfer relationship, with due allowance for any siginificant radiation effects. A discussion is given of the mechanism of the combustion process during the burning of a fuel spray.

DIRECT-FORCE MEASUREMENTS OF TURBULENT SKIN FRICTION ON CYLINDERS IN AXIAL FLOW AT SUBSONIC AND SUPERSONIC VELOCITIES. Dean R. Chapman and Robert H. Kester. 1953. 20p. diagrs., photos., tab. (To be presented at annual Institute of the Aeronautical Sciences meeting, New York, January 26-29, 1953.)

The principal results of a study of all known theories for calculating turbulent skin friction in compressible flow are briefly reviewed. These various theories predict widely different effects of Mach number on skin friction, and hence also on heat transfer. Systematic experiments were made to determine the magnitude of turbulent skin friction along the cylindrical portion of cone-cylinder bodies of revolution having over-all fineness ratios of 10, 15, and 25. Data were obtained by directly measuring forces. Boundary-layer surveys were made to determine the correction necessary to apply to the force measurements in order to determine the effective starting position of the turbulent flow. Mach numbers between 0.5 and 3.6, and Reynolds numbers between 4 million and 32 million were investigated. At a Mach number of 2.0, data were obtained (by

distorting the flexible-plate walls of the wind tunnel) for three different pressure distributions in order to evaluate the effect of a moderate pressure gradient on turbulent skin friction.

CURRENT NACA REPORTS

NACA TN 2792

DIRECT-READING DESIGN CHARTS FOR 24S-T3 ALUMINUM-ALLOY FLAT COMPRESSION PANELS HAVING LONGITUDINAL FORMED HAT-SECTION STIFFENERS AND COMPARISONS WITH PANELS HAVING Z-SECTION STIFFENERS. William A. Hickman and Norris F. Dow. March 1953. 71p. photos., diagrs., 8 tabs. (NACA TN 2792)

Direct-reading design charts are presented for the determination of the stress and proportions of 24S-T3 aluminum-alloy flat compression panels having longitudinal formed hat-section stiffeners, for given values of intensity of loading, skin thickness, and effective length. Hat- and Z-stiffened panels are compared as compression panels and as the covers of box beams.

NACA TN 2889

ESTIMATION OF HYDRODYNAMIC IMPACT LOADS AND PRESSURE DISTRIBUTIONS ON BODIES APPROXIMATING ELLIPTICAL CYLINDERS WITH SPECIAL REFERENCE TO WATER LANDINGS OF HELICOPTERS. Emanuel Schnitzer and Melvin E. Hathaway. April 1953. 31p. diagrs. (NACA TN 2889)

An approximate method for computing water loads and pressure distributions of lightly loaded elliptical cylinders during oblique water impacts is presented. The method, of special interest for the case of water landings of helicopters, makes use of theory developed and checked for landing impacts of V-bottom seaplanes. Comparisons of results computed by this method with limited experimental data obtained during drops of a circular cylinder at 0° trim and 90° flight-path angle show rough agreement. A detailed computational procedure is included as an appendix.

NACA TN 2905

A RAPID METHOD FOR USE IN DESIGN OF TURBINES WITHIN SPECIFIED AERODYNAMIC LIMITS. Richard H. Cavicchi and Robert E. English. April 1953. 72p. diagrs., 2 tabs. (NACA TN 2905)

Basic thermodynamic relations were applied to axial-flow turbine designs for which specified aerodynamic limits were set in order to evolve a rapid method of determining turbine velocity diagrams. The method is presented in both chart and tabular form. Illustrative examples show the manner of selecting the number of turbine stages, the optimum work division between or among the stages, and the proximity of the staging operation to the aerodynamic limits.

NACA TN 2916

EFFECT OF THERMAL PROPERTIES ON LAMINAR-BOUNDARY-LAYER CHARACTERISTICS. E. B. Klunker and F. Edward McLean. March 1953. 29p. diagrs. (NACA TN 2916)

An iteration method is presented for solving the laminar-boundary-layer equations for compressible flow in the absence of a pressure gradient wherein the temperature variation of all the fluid thermal properties is considered. Friction and heat-transfer characteristics have been calculated for a stream temperature of -67° F for Mach numbers from 1 to 10 with the use of values of the heat capacity, conductivity, and viscosity determined from experiment. Consideration of the temperature variation of all the fluid thermal properties causes the recovery factor to decrease substantially with increasing Mach number. Moreover, the heat-transfer rate is found to be proportional to the difference between an effective enthalpy, which is a function of both the surface temperature and stream Mach number, and the surface enthalpy. In contrast, the heat-transfer rate is proportional to the difference between the recovery enthalpy and the surface enthalpy for solutions which employ a constant Prandtl number. The calculated skin friction and heat-transfer rates based upon the use of the Sutherland equation for viscosity and a Prandtl number of 0.75, however, are in excellent agreement with the results of the present analysis.

THE ASYMMETRIC ADJUSTABLE SUPERSONIC NOZZLE FOR WIND-TUNNEL APPLICATION. H. Julian Allen. March 1953. 30p. diagrs., photos., 2 tabs. (NACA TN 2919. Formerly RM A8E17)

An asymmetric adjustable nozzle for supersonic wind-tunnel application which permits continuous adjustment of the test-section Mach number is described. The characteristics of this nozzle are compared with the more conventional supersonic tunnel nozzles.

NACA TN 2920

INTERIM REPORT ON A FATIGUE INVESTIGATION OF A FULL-SCALE TRANSPORT AIRCRAFT WING STRUCTURE. M. James McGuigan, Jr. April 1953. 36p. photos., diagrs., 2 tabs. (NACA TN 2920)

Results are presented of constant-level fatigue tests conducted on several full-scale C-46 "Commando" airplane wings at a level of 1 ± 0.625g or about 22 ± 14 percent of the design ultimate load factor. The average lifetime for the 34 fatigue failures that occurred was about 200,000 cycles. The spread in lifetime for all failures was 4.4 to 1.0, whereas for failures repeatedly occurring at the same location it was as small as 1.2 to 1.0. Effective stress concentration factors were calculated for all failures and indicated a value of about 4.0 for an inspection cutout and 2.3 for a riveted tension joint. During the tests no change was noted in either the natural frequency or damping characteristics of the test specimens prior to the development of a fatigue crack. When a crack did occur, its rate of growth was rather slow until about 5 to 9 percent of the tension material had failed, after which the rate of crack growth increased rapidly.

NACA TN 2921

THE AERODYNAMIC DESIGN AND CALIBRATION OF AN ASYMMETRIC VARIABLE MACH NUMBER NOZZLE WITH A SLIDING BLOCK FOR THE MACH NUMBER RANGE 1.27 TO 2.75. Paige B. Burbank and Robert W. Byrne. April 1953. 37p. photos., diagrs., 5 tabs. (NACA TN 2921. Formerly RM L50L15)

A method of designing as asymmetric, fixed geometry, variable Mach number nozzle has been developed by using the method of characteristics. A small nozzle conforming to the analytically determined ordinates was constructed and calibrated over a range of Mach numbers extending from 1.27 to 2.75. The results show the variation in Mach number to be ±0.02 or less and in the flow direction to be ±0.2° within the test section. The range of Mach numbers from 1.27 to 2.75 was obtained by translating the lower block in a straight line parallel to the test-section center line for a distance of 2.17 test-section heights.

NACA TN 2922

THE DESIGN OF VARIABLE MACH NUMBER ASYMMETRIC SUPERSONIC NOZZLES BY TWO PROCEDURES EMPLOYING INCLINED AND CURVED SONIC LINES. Clarence A. Syvertson and Raymond C. Savin. March 1953. 35p. diagrs., tab. (NACA TN 2922)

Two procedures are developed for designing asymmetric supersonic nozzles for which the calculated exit flow is essentially uniform over a range of Mach numbers. One procedure is applicable at Mach numbers below approximately 3; the other procedure is used for designs at Mach numbers exceeding 3.

NACA RM E53B17

ANALYSIS OF HEAT TRANSFER AND FLUID FRICTION FOR FULLY DEVELOPED TURBULENT FLOW OF SUPERCRITICAL WATER WITH VARIABLE FLUID PROPERTIES IN A SMOOTH TUBE. Robert G. Deissler and Maynard F. Taylor. April 1953. 29p. diagrs. (NACA RM E53B17)

A previous analysis of turbulent flow and heat transfer for air with variable properties flowing in smooth tubes is generalized in order to make it applicable to supercritical water. The generalization is necessary because all the pertinent properties of supercritical water vary markedly with temperature. Calculated velocity and temperature distributions, as well as relations among Nusselt number, Reynolds number, and friction factor, are presented. The effect of variation of fluid properties across the tube on the Nusselt number and friction factor correlations can be eliminated by evaluating the properties at a reference temperature which is a function of both the wall temperature and the ratio of wall-to-bulk temperatures.

NACA RM L53A09

LANGLEY FULL-SCALE-TUNNEL TESTS OF THE CUSTER CHANNEL WING AIRPLANE. Jerome Pasamanick. April 1953. 57p. diagrs., photos., tab. (NACA RM L53A09)

An investigation has been made in the Langley full-scale tunnel to determine the lift characteristics and some of the stability and control characteristics of an experimental Custer Channel Wing airplane at zero airspeed and over the low airspeed range. Comparison is made of the airplane static lift characteristics as obtained in the absence of and in the presence of a ground effect with and without the horizontal tail surfaces. An evaluation of the flow field about the channel-propeller combination is included.

THE NATURAL FREQUENCIES OF VIBRATION OF PRISMATIC BLADES WITH PARTICULAR REFERENCE TO A 12-STAGE TURBINE. R. Chaplin. 1952. 25p. diagrs., 3 tabs. (ARC CP 95)

The natural frequencies of vibration of the blading of a 12 stage, 3000 rpm turbine have been measured and compared with the values obtained by calculation. In the calculations for the flexural modes, corrections have been introduced for shear and rotary inertia. An empirical correction is used for the influence of the increase in torsional stiffness, due to the platform, on the frequencies of torsional vibration. The agreement of measured and computed frequencies is sufficient for the purpose of computing critical speeds up to a frequency of five kilocycles per second above which limit the discrepancy increases with the order of the mode.

GRAPHICAL SOLUTION OF MULTHOPP'S EQUATIONS FOR THE LIFT DISTRIBUTION OF WINGS. F. Vandrey. 1952. 8p. diagrs. (ARC CP 96)

A simple graphical method is described facilitating the determination of the lift distribution of wings. The basis is Multhopp's method of replacing approximately the integro-differential equation for the circulation by a finite system of linear equations which give the values of the circulation at certain fixed points along the span. The values of the unknown circulations are represented by scales in a set of diagrams for the equations. The multiplication of the approximate values of the unknowns and the constant coefficients of the equations is effected by auxiliary scales in the diagrams. The corrections of the approximate values are transferred from the auxiliary scales to the main scales by a pair of dividers. The lift distribution of a rectangular wing is determined as a practical example.

SWEPT-WING LOADING. A CRITICAL COMPARISON OF FOUR SUBSONIC VORTEX SHEET THEORIES. H. C. Garner. FOREWORD. L. W. Bryant. 1952. 61p. diagrs., 17 tabs. (ARC CP 102)

From a systematic series of calculations of swept-wing loading the writer has formed an opinion of the accuracy and most useful application of vortex lattice theory and the vortex sheet theories of Weissinger, Multhopp and Küchemann. The results provide a general picture of the effect of sweep and compressibility on lift slope and aerodynamic center.

SOME EFFECTS OF REYNOLDS NUMBER ON A CAMBERED WING AT HIGH SUBSONIC MACH NUMBERS. H. E. Gamble. 1952. 34p. photos., diagrs., 2 tabs. (ARC CP 103)

An untapered, sweptback wing of aspect ratio 4, sweepback 25° and section 12-percent thick (RAE 104 with 1-percent camber, a = 0.6) was tested in the RAE high-speed tunnel. The pressure distribution was measured at the midsemispan section at various Mach numbers up to 0.88 at Reynolds numbers of 0.8, 1.8 and 3.5×10^{6}. There are considerable differences in the shapes of the pressure distributions at the three Reynolds numbers, although the boundary layer was laminar back to about 70-percent of the chord in all cases. At the highest Reynolds number, the suctions on the upper surface at high Mach numbers increase from the leading-edge of the wing right up to about 50 percent or 60 percent of the chord, while at the lowest Reynolds number they remain almost constant from about 30 percent to about 60 percent of the chord. This flat-topped pressure distribution, which is associated with a λ-type shock wave, results in lower lift coefficients and higher pitching-moment coefficients than those obtained at higher Reynolds number. Brief experiments, with transition provoked near the leading edge, indicate that the shape of the pressure distribution at $R = 0.8 \times 10^{6}$ is then something similar to that obtained at $R = 3.5 \times 10^{6}$ with transition free and at about 65 percent chord. It appears however, that inducing early transition artificially at higher Reynolds numbers can seriously alter the pressure distribution at high speed by causing a forward movement of the shock wave and a separation aft of it.

THE EFFECT OF ENDPLATES ON SWEPT WINGS. D. Küchemann and D. J. Kettle. 1952. 23p. diagrs. (ARC CP 104)

Existing methods of calculating the effect of endplates on straight wings are modified so as to apply to swept wings. The changes in over-all lift and drag, and also the spanwise distribution of the additional load, can be calculated. The theoretical results are compared with experimental results obtained on swept wings, including new measurements of lift, drag and pitching moment, made on an untapered 45° sweptback wing of aspect ratio 3 at low speed. The method of calculation is also extended to cover the effect of the tip vortex which is formed on wings without endplates.

THE DESIGN OF JETTISONABLE COCKPIT HOODS. I. L. Keiller. 1952. 34p. photos., diagrs. (ARC CP 105)

In the past much trouble has been experienced in the design of jettisonable cockpit hoods and even after a considerable amount of development many hoods are not really satisfactory. In order that a successful hood jettisoning mechanism can be produced it is essential that the various problems involved should be realized at the design stage. Consideration is given in this paper to the jettisoning problems involved in the design of all types of hoods and cockpit covers. Certain basic design criteria are proposed and the various methods of meeting them are discussed. Recommendations on good design practice are given where possible. With the knowledge that is at present available the design of a satisfactory orthodox hood should present no great problems, but the more advanced designs are likely to cause some difficulty.

SOME INVESTIGATIONS INTO THE DESIGN OF WIND TUNNELS WITH GAS TURBINE JET ENGINE DRIVES. H. J. Higgs. 1953. 84p. diagrs. (ARC CP 107)

The basic design of wind tunnels suitable for jet engine drives has been investigated by matching the predicted mass flows and total pressure losses of typical tunnel configurations with the estimated mass flow and total pressure rise characteristics of possible pumping systems. There are three possibilities of jet engine pumping (1) induction pumping (2) suction pumping and (3) parallel suction and induction pumping, of which induction pumping is shown to be the most favorable. Using this system a typical 5,000 lb thrust jet engine (such as a R. R. Nene II) can drive (1) a high speed subsonic tunnel of 4 ft^2 working section up to M = 1.0, (2) a supersonic tunnel of 2 ft^2 working section up to M = 1.2, (3) a supersonic tunnel of 1 ft^2 working section up to M = 1.8. For these three cases it has been assumed that humidity effects can be controlled by partial recirculation of the hot engine exhaust gases to raise the working section temperature of 60° C. In the supersonic case 60° might not be sufficient and other methods of humidity control have been discussed in relation to jet engine drives. Induction pumping readily allows multiple engine drive, that is, the above working section areas can be increased in proportion to the number of engines used.

ON THE FLOW PAST A FLAT PLATE WITH UNIFORM SUCTION. B. Thwaites. 1952. 11p. diagrs., tab. (ARC R & M 2481. Formerly ARC 9391; FM 887; Perf. 113)

A new method of performing boundary-layer calculations is introduced in this paper, and is applied to the problem of finding the characteristics of uniform flow past a flat plate through which there is a constant normal velocity. An exact solution to this problem has not yet been found and it is therefore difficult to assess the accuracy of the results obtained. The results, however, are compared with those of two other methods. The new method will be applied to other problems. When the momentum eauation is being used, one obvious advantage of the method is that, in "adding" velocity profiles, the momentum thickness of each may be added to give the momentum thickness of the whole. This is not so in the usual methods of boundary-layer calculations, and great simplification is thereby obtained.

NOTE ON THE MAINTENANCE OF LAMINAR-FLOW WINGS. W. E. Gray and H. Davies. 1952. 3p. (ARC R & M 2485; ARC 10,518. Formerly RAE Tech. Note Aero 1862)

The maintenance of laminar-flow wings involves: (1) the prevention of deterioration in the surface itself (for example, cracking of the paint or filler, increase in roughness or waviness, etc., whether due to weathering, stresses in flight, or accidental damage) and (2) the prevention of contamination of the surface with flies, etc. This report gives an account of experience gained at the Royal Aircraft Establishment in dealing with these problems during flight tests on the characteristics of low-drag wings.

A SERIES OF LOW-DRAG AEROFOILS EMBODYING A NEW CAMBER-LINE. Ola Douglas. 1952. 19p. diagrs., tabs. (ARC R & M 2494; ARC 10,620)

A series of low-drag airfoils is displayed in this paper, which introduces a new stock type of camber line. This camber line affords several advantages: in particular, it makes it possible for any one of the parameters C_L range, ρ_L, $C_{L_{opt}}/C_{m0}$ and M_{crit} to take values appreciably higher than can be obtained by previous methods, the remaining parameters being fixed. The method of design follows that of R & M 2166 and the greater part of the work involves standardized computational processes. The design of one of the series is described in detail, and one is also compared, favorably, with a corresponding roof-top airfoil. A method is given of obtaining easily an approximate value for the lower limit of the C_L range when the upper limit is known.

INVESTIGATIONS INTO THE EFFECT OF CONTINUOUS SUCTION ON LAMINAR BOUNDARY-LAYER FLOW UNDER ADVERSE PRESSURE GRADIENTS. B. Thwaites. 1952. 23p. diagrs., tab. (ARC R & M 2514. Formerly ARC 9555; FM 912)

The principal problem considered in this paper is that of the flow along a surface through which fluid is being continuously withdrawn at a constant velocity, the velocity of the stream outside the boundary layer having a constant and negative gradient. When no suction is applied Howarth has solved the flow, and the point of separation is known. With continuous suction, the ordinary methods of using the momentum equation, for example Pohlhausen's method, breakdown, and a new method is used in this paper to find the point of separation when suction of constant velocity is applied. Only partial success may be recorded in this problem, but this account of progress so far is now given in the hope that the problem may attract other workers. The new method of boundary-layer calculation used is not fully described in this paper, and will be explained with examples of its use, in a later paper. It has already been used in R & M 2481, where a particular problem was treated with great ease. The momentum equation of boundary-layer flow is also used to deduce other types of flow in which the velocity of suction or the velocity outside the boundary layer is not constant. These examples are inserted by virtue of the simplifications of method involved, by which the momentum equation may be integrated exactly; one of them is particularly applicable to the velocity distribution near the leading edge of a thin airfoil at high lift coefficient, in which a small amount of suction is sufficient to prevent the stall. There are appended some considerations of the practical applications of the continuous suction principle, and also some figures showing the quantities of fluid required to be sucked in, given for the benefit of designers who may not realize how small are the quantities of fluid sucked when separation of flow is suitably prevented. The application of continuous suction to delay the stall is stressed.

AN EXPERIMENTAL INVESTIGATION ON THE FLUTTER CHARACTERISTICS OF A MODEL FLYING WING. N. C. Lambourne. 1952. diagrs., photos., 6 tabs. (ARC R & M 2626. Formerly ARC 10,509; 0.655)

This report describes some preliminary experimental work that has been carried out in an attempt to gain information on the flexural-torsional flutter characteristics of flying wing types of aircraft. Tests were made with two flexible tip-to-tip models: (a) rectangular plan form and (b) cranked and tapered plan form. The method of supporting the models in the wind tunnel allowed certain bodily freedoms to be present either singly or simultaneously, and measurements were made of critical speeds and frequencies, and in a few cases the flutter motion was analyzed by means of cinematograph records. The experimental results are in no way conclusive and cannot be directly applied to full-scale problems, but they do point to some of the difficulties in the treatment of the flutter of flying wings. Further the difficulties encountered during the flutter tests themselves lead to suggested modifications in the technique of providing a model in a wind tunnel with the bodily freedoms appropriate to free flight conditions.

A CRITERION FOR THE PREVENTION OF SPRING-TAB FLUTTER. A. R. Collar and G. D. Sharpe. 1952. 19p. diagrs., 3 tabs. (ARC R & M 2637; ARC 9104; ARC 9956. Formerly RAE SME 3346; SME 3378)

The present paper advances a formula which can be used as a criterion for the degree of mass balance

necessary for the avoidance of spring-tab flutter. The formula shows that if the tab is of sufficiently light construction, mass balance may not be required at all; on the other hand, the usual static balance may be inadequate for a tab of high inertia. The criterion comprehends within itself the requirement (given elsewhere) limiting the length of a mass balance arm. While the formula is based on theoretical considerations, the numerical values for the quantities to be used have been deduced from flight experience, which shows excellent correlation with the theory. Two forms for the criterion are given: a simple form suitable for general application, and a slightly elaborated form intended for application to unusually large tabs. The appendix, besides containing the main analysis, also gives consideration to certain factors which for simplicity are omitted in the main text. In particular it is shown that the "limiting length" for a balance arm may be generalized to a "limiting circle" for the position of the balance mass: the circle can often be found from simple geometrical considerations.

PERFORMANCE CALCULATIONS FOR A DOUBLE-COMPOUND TURBO-JET ENGINE OF 12:1 DESIGN COMPRESSOR PRESSURE RATIO. D. H. Mallinson and W. G. E. Lewis. 1952. 29p. diagrs. (ARC R & M 2645; ARC 11,355. Formerly NGTE R. 19)

This report describes a theoretical investigation using conventional component characteristics to discover that division of work between the low and high-pressure compressors of a double-compound simple-jet gas turbine of 12:1 design pressure ratio which is likely to result in the most desirable equilibrium operation over the normal engine speed range. Having decided in favor of a pressure ratio of 3:1 in the low-pressure compressor and 4:1 in the other, a study is then made using more realistic compressor characteristics to determine the probable performance of such an engine under all flight conditions when the design maximum temperature is 900° C (1173° K). The equilibrium running conditions of the engine are investigated with special reference to the problems introduced by the double-compound type of design.

COMPRESSION TESTS ON DURAL-CELLUBOARD SANDWICH PANELS. K. H. V. Britten. 1952. 18p. diagrs., photos., 5 tabs. (ARC R & M 2658; ARC 10,427. Formerly RAE Tech. Note SME 383)

Results are given of compression tests made on 56 dural-Celluboard sandwich panels with birch spruce or whitewood centers. These are compared with results from similar tests on dural-balsa sandwich and all-metal panels, and it is seen that over a range of sizes and weights considered dural-Celluboard can be equally or more efficient for carrying end loads. The birch Celluboard was more efficient than the spruce or whitewood and the thicker sandwiches, and those with thicker skins were more efficient than the thinner specimens. The maximum stress reached in the skin, 48,000 lb/sq in., was equal to the 0.1 percent tensile proof stress of the material. The birch filling had also reached its maximum compression stress, 8,000 lb/sq in. The design had therefore exploited these materials to their fullest extent.

DESIGN AND CALIBRATION TESTS OF A 5.5 IN. SQUARE SUPERSONIC WIND TUNNEL. J. Lukasiewicz. 1952. 36p.photos., diagrs., 4 tabs. (ARC R & M 2745; ARC 13,425. Formerly RAE Tech. Note Aero 2033, sup. 100)

The main design features of the wind tunnel are described and results are given of the investigations carried out to determine: (a) the minimum pressure ratio required to operate the wind tunnel at Mach numbers up to 3.5, and (b) the uniformity of the velocity distribution in the working section at Mach numbers of 1.57, 1.88, 2.48, 2.85, 3.25 and 3.5. It was found that the tunnel pressure recovery can

be appreciably increased by means of a contraction ("second throat") located between the working section and subsonic diffuser. All nozzles tested were designed with short throats and expansion profiles with the maximum angles of expansion for the given exit Mach number. The axial variation of Mach number over selected intervals of working section (not smaller than 5 in.) was found to be of the order of ±1.0 percent. It was found that condensation in the wind-tunnel nozzle (run with atmospheric air) has a detrimental effect on the velocity distribution in the working section, particularly at small Mach numbers.

INVESTIGATIONS ON STALLING BEHAVIOUR, RUDDER OSCILLATIONS, TAKE-OFF SWING AND FLOW ROUND NACELLES ON THE TUDOR I AIRCRAFT. D. J. Lyons. 1952. 18p. diagrs., 2 tabs. (ARC R & M 2789; ARC 11,412. Formerly RAE Aero 2237)

During the development of the Tudor I aircraft, the Royal Aircraft Establishment cooperated in the flight tests. This report summarizes the results, which are felt to be of general interest. The importance of "deep tufting" in leading to an understanding of varied aerodynamic problems has again been forcibly demonstrated; namely in showing that: (a) early buffeting of the Tudor as the stall is approached was due to a very small airleak around the leading edge of the wing root causing a breakaway of flow, the resultant wake of which hit the tailplane; (b) early wing-tip stalling was shown to be due to small malfitment of the T.K.S. de-ciers; (c) rudder "kicking" arose from flow through the hinge cutouts; (d) excessive take-off swing was due to poor rudder control as a result of the early rudder stall, and to the fact that the aircraft was stalled in the ground attitude; and (e) the inner nacelle needed considerable lengthening.

N-21598*

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL MEASUREMENTS OF YAWING MOMENT DUE TO YAWING (n_r) ON A 1/5.5 SCALE MODEL OF THE METEOR MARK F.III. J. G. Ross and R. C. Lock. 1952. 31p. diagrs., photos., 10 tabs. (ARC R & M 2791; ARC 10,786. Formerly RAE Aero 2199)

During recent investigations into the self-excited oscillations in yaw, experienced on Meteor aircraft, the lateral stability derivative n_r was measured in flight, and found to differ considerably during initial experiments from the theoretical estimate. A new technique was therefore devised to measure n_r in the wind-tunnel; and, with its aid, modifications were tested on a model with the object of reducing the self-excited oscillations in flight. Measurements of n_r were made over a range of Reynolds numbers, and for different periods of oscillation of the model. The final comparison of the flight and wind-tunnel tests, after certain refinements in technique of the former, and after corrections for solid friction to the latter had been made, showed that the full-scale measurement of n_r was about 10 percent less than that obtained in the tunnel. Considering the difficulties involved, this agreement may be considered as satisfactory. For the model in the standard condition, the value of n_r was about 20 percent less than the estimated figure of -0.108 at zero lift, but with dorsal fins. It was found possible, without altering the value of n_v, to increase the value of n_r to the estimated value. The "snaking" tendencies of the model, which were more pronounced at small angles of incidence, could be greatly reduced by fitting an upper dorsal fin.

NACA Rept. 1085

DISCUSSION OF BOUNDARY-LAYER CHARACTERISTICS NEAR THE WALL OF AN AXIAL-FLOW COMPRESSOR. Artur Mager, John J. Mahoney and Ray E. Budinger. 1952. ii, 20p. diagrs., photo., tab. (NACA Rept. 1085. Formerly RM E51H07)

Boundary-layer velocity profiles on the casing of an axial-flow compressor behind the guide vanes and rotor were measured and resolved into two components: along the streamline of the flow and perpendicular to it. Boundary-layer thickness and the deflection of the boundary layer at the wall were the generalizing parameters. By use of these results and the momentum-integral equations, the characteristics of boundary layer on the walls of axial-flow compressor are qualitatively discussed. Important parameters concerning secondary flow in the boundary layer appear to be turning of the flow and the product of boundary-layer thickness and streamline curvature outside the boundary layer. Two types of separation are shown to be possible in three dimensional boundary layer.

NACA Rept. 1088

THEORETICAL DAMPING IN ROLL AND ROLLING MOMENT DUE TO DIFFERENTIAL WING INCIDENCE FOR SLENDER CRUCIFORM WINGS AND WING-BODY COMBINATIONS. Gaynor J. Adams and Duane W. Dugan. 1952. ii, 11p. diagrs. (NACA Rept. 1088. Extends analysis of TN 2270)

A method of analysis based on slender-wing theory is developed to investigate the characteristics in roll of slender cruciform wings and wing-body combinations. The method makes use of the conformal mapping processes of classical hydrodynamics which transform the region outside a circle and the region outside an arbitrary arrangement of line segments intersecting at the origin. The method of analysis may be utilized to solve other slender cruciform wing-body problems involving arbitrarily assigned boundary conditions.

NACA TN 2923

STUDY OF MOTION OF MODEL OF PERSONAL-OWNER OR LIAISON AIRPLANE THROUGH THE STALL AND INTO THE INCIPIENT SPIN BY MEANS OF A FREE-FLIGHT TESTING TECHNIQUE. Ralph W. Stone, Jr., William G. Garner and Lawrence J. Gale. April 1953. 28p. diagrs., photos., tab. (NACA TN 2923)

This paper presents the motion of a dynamic model through the stall and into the incipient spin. The results indicate that, after the initial stall, the model became unstalled, inverted, and assumed very low angles of attack before restalling and entering the incipient spin. Altitude loss and angular velocities were relatively small during the early part of the motion and indicated that this time would be the optimum time to terminate the motion by control movement.

NACA TN 2925

LIFT DEVELOPED ON UNRESTRAINED RECTANGULAR WINGS ENTERING GUSTS AT SUBSONIC AND SUPERSONIC SPEEDS. Harvard Lomax. April 1953. 44p. diagrs., 2 tabs. (NACA TN 2925)

Lift forces induced by a vertical gust are estimated on the basis of theoretical calculations. The effects of pitching and wing bending are neglected and only wings of rectangular plan form are considered. However, the effects of Mach number (from 0 to 2) and aspect ratio (2 to ∞) are included, and solutions are given by means of which the response to gusts having arbitrary streamwise gradients can be calculated. Results are presented for sharp-edged and triangular gusts and various wing-air density ratios.

NACA TN 2931

A METHOD FOR DETERMINING CLOUD-DROPLET IMPINGEMENT ON SWEPT WINGS. Robert G. Dorsch and Rinaldo J. Brun. April 1953. 29p. diagrs. (NACA TN 2931)

The general effect of wing sweep on cloud-droplet trajectories about swept wings of high aspect ratio moving at subsonic speeds is discussed. A method of computing droplet trajectories about yawed cylinders and swept wings is presented, and illustrative droplet trajectories are computed. A method of extending two-dimensional calculations of droplet impingement on nonswept wings to swept wings is presented. It is shown that the extent of impinge-

ment of cloud droplets on an airfoil surface, the total rate of collection of water, and the local rate of impingement per unit area of airfoil surface can be found for a swept wing from two-dimensional data for a nonswept wing. The impingement on a swept wing is obtained from impingement data for a nonswept airfoil section which is the same as the section in the normal plane of the swept wing by calculating all dimensionless parameters with respect to flow conditions in the normal plane of the swept wing.

NACA RM E52L23a

FREE FALL AND EVAPORATION OF n-OCTANE DROPLETS IN THE ATMOSPHERE AS APPLIED TO THE JETTISONING OF AVIATION GASOLINE AT ALTITUDE. Herman H. Lowell. April 1953. 25p. diagrs. (NACA RM E52L23a)

In connection with proposed rapid jettisoning of aviation gasoline at altitude, a theoretical study was made of the free fall and evaporation of n-octane droplets in the atmosphere; n-octane was selected for study because of the expected similarity of overall evaporation behavior of n-octane and gasoline. It was concluded that gasoline (or n-octane) droplets larger than 2000 microns in diameter would be unstable; terminal speeds and Reynolds numbers were obtained for droplets not larger than 2000 microns at altitudes to 11,000 feet. The motion data were used in the calculation of n-octane evaporation rates under various conditions. It was found that a droplet having an original diameter of 2000 microns would fall about 4000 feet from 6000 feet under NACA standard atmosphere conditions before coming virtually to rest. Finally, it was concluded that temperature effects are of paramount importance; at highest air temperatures a 1000-foot ground clearance would probably be adequate to prevent ground contamination, whereas at lowest air temperatures only an atomizing spray arrangement would prevent ground contamination, irrespective of ground clearance.

INTERNAL FRICTION AND GRAIN BOUNDARY VISCOSITY OF SILVER AND OF BINARY SILVER SOLID SOLUTIONS. S. Pearson. January 1953. 22p. diagrs., 4 tabs. (RAE Met. 71)

Measurements have been made of the variation of internal friction with temperature for spectroscopically pure silver and for a series of solid solutions of silver with cadmium, indium, and tin, using a Kê type torsion pendulum apparatus. Some experiments have also been made to investigate the effect of nonmetallic impurity on grain boundary relaxation in silver. The effect of the alloying elements is to increase the grain boundary viscosity and to raise the activation energy for grain boundary relaxation from 22,000 cal/mole for pure silver to 43,000 cal/mole for the solid solutions, the same value being obtained, within the limits of experimental error, for all the alloying elements and for all the solute concentrations investigated. The results of the experiments show exactly the same trend as those obtained previously for a similar series of copper solid solutions. They are in agreement with the general theory of grain boundary relaxation developed by Zener and Kê but do not seem to be in agreement with either of the mechanisms so far put forward to explain grain boundary slip.

THE OXIDIZING NITRATION OF NITROSO COMPOUNDS AND ARYLHYDROXYLAMINES. (Okislitel'nole nitrovanie aromaticheskikh nitrozosoedinenii i arilgidroksilaminov). A. I. Titov and N. G. Laptev. EXPERIMENTAL PROCEDURE, by A. I. Titov, N. G. Laptev and A. N. Baryshnikova. 11p. (Trans. from Zhurnal Obshchei Khimii, v. 18, pt. 1, 1948, p. 741-748).

It is shown that the aromatic nitroso compounds and arylhydroxylamines under the action of nitric acid containing nitrogen oxides may undergo very different transformations leading to the formation of a mixture of the corresponding nitro compounds, diazo compounds, p-dinitroso compounds, p-nitrosodiarylhydroxylamines, oxalic acid, and nitrophenols containing hydroxyl in the para position relative to the place previously occupied by the nitroso group. Mechanisms for these reactions are proposed. Detailed procedure is given for performing the nitration.

N-22620*

ON THE MECHANISM OF THE NITRATION OF AROMATIC COMPOUNDS BY A SULFURO-NITRIC ACID MIXTURE AND OTHER ENERGETICALLY NITRATING MEANS. (O mekhanizme nitrovaniya aromaticheskikh soedinenii sernoazotnoi smes'yu i drugimi energichno nitruyushchimi sredstvani). A. I. Titov. 13p. (Trans. from Zhurnal Obshchei Khimii, v. 18, pt. 1, 1948, p. 733-740).

The nitration by nitric acid of benzene and other aromatics possessing a nuclear affinity equal to or less than that of benzene, occurs principally through an intermediate interaction with various forms of nitrogen dioxide only at low concentrations of the acid. The authors attempt to explain this phenomenon.

CURRENT NACA REPORTS

NACA Rept. 1075

HYDRODYNAMIC IMPACT OF A SYSTEM WITH A SINGLE ELASTIC MODE. II-COMPARISON OF EXPERIMENTAL FORCE AND RESPONSE WITH THEORY. Robert W. Miller and Kenneth F. Merten. 1952. ii, 7p. diagrs., photos., tab. (NACA Rept. 1075. Formerly TN 2343)

Hydrodynamic impact tests were made on an elastic model approximating a two-mass-spring system which had a ratio of sprung mass to hull mass of 0.6 and a natural frequency of 3.0 cycles per second. Tests were made at two combinations of trim and flight-path angles and for a range of flight-path velocity. Comparison of the experimental results with results obtained from the theory of NACA TN 1398 showed good agreement.

NACA Rept. 1078

EFFECTS OF COMPRESSIBILITY ON THE PERFORMANCE OF TWO FULL-SCALE HELICOPTER ROTORS. Paul J. Carpenter. 1952. ii, 8p. diagrs., photo. (NACA Rept. 1078. Formerly TN 2277)

An investigation has been conducted on the Langley helicopter test tower to determine experimentally the effects of compressibility on the performance and blade pitching moments of two full-scale helicopter rotors with twisted and untwisted blades over a tip-speed range from 350 to 770 feet per second.

NACA Rept. 1081

A STUDY OF SECOND-ORDER SUPERSONIC FLOW THEORY. Milton D. Van Dyke. 1952. ii, 23p. diagrs. (NACA Rept. 1081. Formerly TN 2200)

Second-order solutions of supersonic-flow problems are sought by iteration, using the linearized solution as the first step. For plane and axially symmetric flows, particular solutions of the iteration equation are discovered which reduce the second-order problem to an equivalent linearized problem. Comparison of second-order solutions with exact and numerical results shows great improvement over linearized theory. For full three-dimensional flow, only a partial particular solution is found. The inclined cone is solved, and the possibility of treating more general problems is considered.

NACA Rept. 1089

SINGLE-DEGREE-OF-FREEDOM-FLUTTER CALCULATIONS FOR A WING IN SUBSONIC POTENTIAL FLOW AND COMPARISON WITH AN EXPERIMENT. Harry L. Runyan. 1952. ii, 8p. diagrs. (NACA Rept. 1089. Formerly TN 2396)

The effect of Mach number and structural damping on single-degree-of-freedom pitching of a wing is presented. Some experimental results are compared with theory and good agreement is found for certain ranges of an inertia parameter.

NACA TN 2926

STATIC FORCE-DEFLECTION CHARACTERISTICS OF SIX AIRCRAFT TIRES UNDER COMBINED LOADING. Walter B. Horne. May 1953. 92p. diagrs., photos., 2 tabs. (NACA TN 2926)

Static force-deflection tests were made on six aircraft tires. These tests included the vertical loading of the six tire specimens, combined vertical loading and side loading and combined vertical loading and torsional loading of five tire specimens, and combined vertical loading and fore-and-aft (longitudinal) loading of one tire specimen for different initial inflation pressures. Tire deflection, vertical-load center-of-pressure shifts, and tire pressure measurements are presented for the different load combinations. The lateral spring constants for all the tire specimens tested decreased with increasing vertical tire deflection; whereas, the torsional and fore-and-aft spring constants increased with increasing vertical tire deflection. The lateral and fore-and-aft shifts of the vertical-load center of pressure were found to average 75 percent and 25 percent, respectively, of the side and fore-and-aft tire deflections.

NACA TN 2927

DEFLECTION OF DELTA WINGS HAVING A CARRY-THROUGH-BAY CHORD SMALLER THAN THE WING ROOT CHORD. Roger W. Peters and Manuel Stein. May 1953. 25p. diagrs., photo., 2 tabs. (NACA TN 2927)

Experimentally determined influence coefficients are presented for the deflection of two solid delta wings - one wing of constant thickness and the other of constant thickness ratio - having a carry-through-bay chord smaller than the wing root chord. A theoretical method of analysis is demonstrated for the constant thickness wing under tip load, and the theoretical results are compared with the experimental results.

NACA TN 2928

AXIAL-LOAD FATIGUE PROPERTIES OF 24S-T AND 75S-T ALUMINUM ALLOY AS DETERMINED IN SEVERAL LABORATORIES. H. J. Grover and W. S. Hyler, Battelle Memorial Institute, Paul Kuhn and Charles B. Landers, Langley Aeronautical Laboratory and F. M. Howell, Aluminum Company of America. May 1953. 63p. photos., diagrs., 7 tabs. (NACA TN 2928)

In the initial phase of an NACA program on fatigue research, axial-load tests on 24S-T3 and 75S-T6 aluminum-alloy sheet have been made at the Battelle Memorial Institute and at the Langley Aeronautical Laboratory of the NACA. The test specimens were polished and unnotched. The manufacturer of the material, the Aluminum Company of America, has made axial-load tests on 24S-T4 and 75S-T6 rod material. The test techniques used at the three laboratories are described in detail; the test results are compared with each other and with results obtained on unpolished sheet by the National Bureau of Standards.

NACA TN 2929

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF REAR-FUSELAGE SHAPE ON DITCHING BEHAVIOR. Ellis E. McBride and Lloyd J. Fisher. April 1953. 35p. diagrs., photos., 3 tabs. (NACA TN 2929)

An experimental investigation was conducted to determine the effect of rear-fuselage shape on ditching behavior. The basic fuselages were streamline bodies of revolution of fineness ratios 6 and 9. Variations in longitudinal curvature were obtained by sweeping up or sweeping down the rear half of the center line. A change in the cross section was obtained by splitting the center line in the plan view. The models were landed in calm water at speeds of 30, 40, 50, and 60 feet per second. The effects on ditching behavior of changes in longitudinal curvature, cross section, fuselage fineness ratio, and landing speed are presented in terms of maximum height of the center of gravity, maximum attitude, length of run, and skipping tendency.

NACA TN 2932

WATER-LANDING INVESTIGATION OF A FLAT-BOTTOM V-STEP MODEL AND COMPARISON WITH A THEORY INCORPORATING PLANING DATA. Robert W. Miller. May 1953. 23p. diagrs., photo., 2 tabs. (NACA TN 2932)

This paper presents the results of a fixed-trim smooth-water impacts of a flat-bottom V-step model having a high beam loading. Plots of nondimensional load, draft, vertical velocity, and time against flight-path angle at water contact show results similar to those exhibited by other models having transverse steps, high beam loadings, and different shapes. Time-history comparisons show good agreement between experimental results and results computed by the method of NACA TN 2814 for the V-step case.

NACA TN 2934

RELATION BETWEEN ROUGHNESS OF INTERFACE AND ADHERENCE OF PORCELAIN ENAMEL TO STEEL. J. C. Richmond, D. G. Moore, H. B. Kirkpatrick and W. N. Harrison, National Bureau of Standards. April 1953. 29p. diagrs., photos., 7 tabs. (NACA TN 2934)

The relationship between adherence and roughness of interface between enamel and iron was studied. Porcelain-enamel ground coats were prepared and applied under conditions that gave various degrees of adherence. The variations were produced by (a) varying the amount of cobalt-oxide addition in the frit; (b) varying the type of metallic-oxide addition in the frit, keeping the amount constant at 0.8 weight percent; (c) varying the surface treatment of the metal before application of the enamel, by pickling, sandblasting, and polishing; and (d) varying the time of firing of the enamel containing 0.8 percent of cobalt oxide. A positive correlation was found between adherence and roughness of the interface.

NACA TN 2936

COMBUSTION INSTABILITY IN AN ACID-HEPTANE ROCKET WITH A PRESSURIZED-GAS PROPELLANT PUMPING SYSTEM. Adelbert O. Tischler and Donald R. Bellman. May 1953. 50p. diagrs., photo. (NACA TN 2936. Formerly RM E51G11)

The low-frequency instability problem of a rocket using liquid propellants and a pressurized-gas propellant pumping system was experimentally investigated with a 300-pound thrust acid-heptane rocket. The results were compared to results predicted by an analysis based on the premise that the instability was due to an out-of-phase coupling between propellant flow and combustion-chamber pressure. The calculated instability frequency conformed with those observed experimentally and the analysis predicted many of the observed trends of varying rocket design or operating parameters.

NACA TN 2937

METHOD FOR CALCULATING THE ROLLING AND YAWING MOMENTS DUE TO ROLLING FOR UNSWEPT WINGS WITH OR WITHOUT FLAPS OR AILERONS BY USE OF NONLINEAR SECTION LIFT DATA. Albert P. Martina. May 1953. 41p. diagrs., 11 tabs. (NACA TN 2937)

The methods of NACA Reports 865 and 1090 have been applied to the calculation of the rolling- and yawing-moment coefficients due to rolling for unswept wings with or without flaps or ailerons. The methods allow the use of nonlinear section lift data together with lifting-line theory. Two calculated examples are presented in simplified computing forms in order to illustrate the procedures involved.

NACA TN 2938

ANALYSIS OF HEAT ADDITION IN A CONVERGENT-DIVERGENT NOZZLE. Donald P. Hearth and Eugene Perchonok. April 1953. 18p. diagrs. (NACA TN 2938)

The effect of heat addition to a divergent stream with initially sonic flow is analyzed and the variation of exit Mach number, static pressure, and total pressure is presented. Application of these results to the diverging portion of a convergent-divergent nozzle indicated that nozzle heat addition delays nozzle overexpansion and affects the jet thrust appreciably. Moreover, misleading nozzle coefficients will be computed if heat addition in the nozzle is ignored.

NACA TN 2939

OPTIMUM CONTROLLERS FOR LINEAR CLOSED-LOOP SYSTEMS. Aaron S. Boksenbom, David Novik and Herbert Heppler. April 1953. 27p. diagrs. (NACA TN 2939)

An analysis is made for optimum controllers of general, linear, time-invariant multiloop systems based on minimizing the mean squares or integral squares of errors and constrained variables for either stationary statistical or transient inputs. A general method of using open-loop optimum filter theory is derived that assures structural stability of the closed-multiloop system during the optimization process. General solutions were obtained for certain special cases and applied to examples of turbojet engine control.

NACA TN 2940

EFFECT OF HIGH BULK TEMPERATURES ON BOUNDARY LUBRICATION OF STEEL SURFACES BY SYNTHETIC FLUIDS. S. F. Murray, Robert L. Johnson and Edmond E. Bisson. May 1953. 27p. diagrs., photos., 2 tabs. (NACA TN 2940)

An experimental study was made of the effect of high lubricant bulk temperatures on the boundary lubricating effectiveness with steel surfaces of various types of synthetic fluids considered as lubricants for turbine engines. Synthetic fluids were generally effective lubricants at higher temperatures than comparable petroleums. Lubrication with esters and possibly other fluids is believed to result from formation of a chemisorbed soap film by free acids (contaminants) in the fluid. Failure results from deterioration of metal soap and oxide films, which is influenced by temperature effects on the bulk fluid. Thermal stability can be associated with viscosity grade within a given class; however, no correlation could be made between lubrication failure temperature and the viscosity at failure temperatures for the various fluids. At temperatures up to its decomposition point, a silicate ester showed more promise than the other lubricants studied.

NACA TN 2944

THE ZERO-LIFT DRAG OF A SLENDER BODY OF REVOLUTION (NACA RM-10 RESEARCH MODEL) AS DETERMINED FROM TESTS IN SEVERAL WIND TUNNELS AND IN FLIGHT AT SUPERSONIC SPEEDS. Albert J. Evans. April 1953. 40p. diagrs., tab. (NACA TN 2944)

Presents zero-lift drag data of an NACA RM-10 slender body of revolution with and without stabilizing fins attached. The results from several wind tunnels and in flight are compared. The results cover a Reynolds number range from about 1×10^6 to 40×10^6 for the wind-tunnel models and 12×10^6 to 140×10^6 for the flight models. The Mach numbers covered include 1.5 to 2.4 in the wind tunnels and 0.85 to 2.5 in flight.

NACA TN 2948

INVESTIGATION OF LATERAL CONTROL NEAR THE STALL. FLIGHT INVESTIGATION WITH A LIGHT HIGH-WING MONOPLANE TESTED WITH VARIOUS AMOUNTS OF WASHOUT AND VARIOUS LENGTHS OF LEADING-EDGE SLOT. Fred E. Weick, Maurice S. Sevelson, James G. McClure and Marion D. Flanagan, Agricultural and Mechanical College of Texas. May 1953. 61p. diagrs., photos., 4 tabs. (NACA TN 2948)

Flight tests were made with a light high-wing monoplane to investigate possibilities for obtaining satisfactory lateral control at low flight speeds. The airplane was tested with a plain straight wing, with the wing twisted to various amounts of washout, and with leading-edge slots covering various portions of the span. With each wing configuration the tests were repeated with power on and off and for three center-of-gravity locations. The flow over the wing was observed by means of tufts attached to the upper surface. The results of the tests indicate that reliable control at angles of attack very near the stall can be achieved by the proper use of leading-edge slots and wing washout.

NACA TM 1347

REPORT ON THE SPECIAL FIELD "INTERFERENCE" TO THE WIND-TUNNEL COMMITTEE IN FEBRUARY 1945. (Bericht über das Fachgebiet Interferenz vor dem Windkanalausschuss im Februar 1945). H. Schlichting. Includes: Compilation of Interference Systematics at the Aerodynamic Institute of the Technical Academy Braunschweig. E. Moller. May 1953. 46p. diagrs. (NACA TM 1347. Trans. from Technische Hochschule Braunschweig. Aerodynamisches Institut. Bericht 45/4)

Contains an outline of investigations dealing with interference effects on the static stability of various airplane configurations that were conducted, were being conducted, and were started at the time of this present report. Results of several investigations are presented and discussed briefly. A supplement is attached showing the configurations tested and outlining the various test programs. Suggestions for future investigations are also included.

NACA TM 1353

SOME PROBLEMS OF THE THEORY OF CREEP. (Nekotorye Voprosy Teorii Polzuchesti). Y. N. Rabotnov. April 1953. 19p. diagrs. (NACA TM 1353. Trans. from Vestnik Moskovskovo Universiteta, no. 10, 1948, p.81-91).

A theory of creep is proposed which represents an extension of the theory of elastic heredity of Volterra to plastic deformation. The theory is applied to the problems of relaxation, reverse creep, creep-bending of bars, and creep of a pipe under internal pressure. A special class of three-dimensional problems, in which the relative magnitudes of the stresses at a point remain constant with time, and likewise the relative magnitudes of the strains, is also considered.

Department of Supply (Australia) TORSION AND BENDING OF SWEPT AND TAPERED WINGS WITH RIGID CHORDWISE RIBS. W. H. Wittrick. September 1950. 85p. diagrs., 24 tabs. (Department of Supply. ACA-51)

The problem considered is that of a swept wing, either conical or cylindrical, of arbitrary section, under any system of bending and torsion loads. The wing is assumed to consist of a nonbuckling outer skin, a series of booms and stringers located along generators of the tube, and a series of closely spaced ribs all parallel to the root section. The ribs are assumed to be completely rigid in their own planes but to offer no resistance to warping out of their own planes. For simplicity only single-cell tubes are considered.

Aeronautical Research Council (Gt. Brit.) NO. 2, $11\frac{1}{2}$-FT WIND-TUNNEL TESTS OF A SMALL SPAN, SMALL CHORD DOUBLE AILERON FOR USE AS A LATERAL CONTROL ON A HIGH-LIFT AIRCRAFT. A. D. Young and W. S. D. Marshall. 1952. 32p. diagrs., 5 tabs. (ARC R & M 2536; ARC 9565. Formerly RAE Aero 2111)

Tests were made on a 1/2.25-scale model of a half wing of the Master. The span of the aileron was 0.22s and the chords were $0.2\bar{c}$ and $0.15\bar{c}$; the aileron was fitted with a balance tab of $0.05\bar{c}$ chord. Measurements were made of the hinge moments, lift increments (from which the rolling moments were deduced), and the pressures in the aileron gaps just above and below the seals. The latter were required for estimating the effect of internal shrouded nose (or pressure) balances. Tests were also made of the effect on the hinge and rolling moments of a small spoiler situated just aft of the front aileron vent; the spoiler was assumed to emerge on the lower surface of the down-going aileron and on the upper surface of the up-going aileron.

Aeronautical Research Council (Gt. Brit.) INFLUENCE OF TUNED DAMPERS ON FLEXURE-AILERON FLUTTER. Part I: THEORETICAL INVESTIGATION ON THE INFLUENCE OF TUNED DAMPING DEVICES ON FLEXURE-AILERON FLUTTER. R. A. Frazer and W. P. Jones. Part II: SOME FURTHER CALCULATIONS ON THE INFLUENCE OF TUNED DAMPING DEVICES ON FLEXURE-AILERON FLUTTER. W. P. Jones. Part III: EXPERIMENTS ON THE EFFECT OF TUNED DAMPING DEVICES ON FLEXURE-AILERON FLUTTER. C. Scruton, D. V. Dunsdon and P. M. Ray. 1952. 31p. diagrs., 5 tabs. (ARC R & M 2559. Formerly ARC 8581; ARC 9946; ARC 9882)

In part I, a general theory has been developed for the investigation of the influence of damping devices of various types on flexure-aileron flutter. The numerical applications refer to a large transport aircraft, and they are restricted to the case of a mass-balanced aileron-carried damper. From the diagrams given at the end of the part, it is inferred that this type of damper would be unsatisfactory as a flutter preventive. Part II supplements part I and gives results for a partly balanced and for a completely balanced aileron-damper system. It is concluded that tuned dampers of these types would also prove unreliable. Part III describes an experimental investigation into the effect on flexure-aileron flutter of a tuned damping device attached to the aileron. The results confirm the theoretical conclusion that the use of an aileron-carried damper would not be a reliable flutter preventive.

Aeronautical Research Council (Gt. Brit.)
COMBUSTION IN THE GAS TURBINE - A SURVEY OF WAR-TIME RESEARCH AND DEVELOPMENT. Peter Lloyd. 1952. 45p. diagrs., 8 tabs. (ARC R & M 2579; ARC 11, 435. Formerly Power Jets Research and Development, Ltd. Special Rept. 510)

The present report attempts a general survey of the whole field of gas-turbine combustion. The report covers both research and development, and while it is mainly concerned with British work, some mention is also made of German work on the same subject. The related processes of combustion in propulsive ducts are briefly touched on. The report is based on a paper to the Institution of Mechanical Engineers, but with much fresh material, including a comprehensive bibliography. There have been many groups of investigators concerned in this work at the Royal Aircraft Establishment, Power Jets, Joseph Lucas and Co., the Asiatic Petroleum Co., Metropolitan Vickers Ltd., Rolls-Royce, Armstrong Siddeley's, De Havillands and the City and Guilds College. In preparing the present report, full use has been made of the work of all these groups and of the Combustion Panel of the Ministry of Aircraft Production's Gas Turbine Collaboration Committee through which they cooperated; this debt is gratefully acknowledged. On the other hand, the interpretation and assessment of the work are the author's, and for these full responsibility is taken.

Aeronautical Research Council (Gt. Brit.)
THE LAMINAR BOUNDARY LAYER ASSOCIATED WITH THE RETARDED FLOW OF A COMPRESSIBLE FLUID. C. R. Illingworth. 1953. 23p. diagrs., 4 tabs. (ARC R & M 2590. Formerly ARC 9886; FM 975)

Two aspects of the solution of the equations governing steady gas flow in a laminar boundary layer, when the main stream velocity is nonuniform, are considered. In the first place, it is shown that the equations can be reduced to ordinary differential equations, whose solution implies the similarity of the distributions of velocity and temperature in planes perpendicular to the boundary, only in the case when the main stream velocity is uniform. In the second part, an extension of Pohlhausen's method is used to determine the point of separation of the boundary layer in an air flow in which the pressure increases with a uniform gradient.

Aeronautical Research Council (Gt. Brit.)
THE ASYMPTOTIC THEORY OF BOUNDARY-LAYER FLOW WITH SUCTION. PART I: THE THEORY OF SIMILAR VELOCITY DISTRIBUTIONS. PART II: FLOW WITH UNIFORM SUCTION. PART III: FLOW WITH VARIATION OF SUCTION VELOCITY. E. J. Watson. 1952. 45p. diagrs., 13 tabs. (ARC R & M 2619. Formerly ARC 9906; FM 977; ARC 10,025; FM 993; ARC 10,317; FM 1063; ARC 10,852; FM 1148)

The subject of this report is the steady two-dimensional flow of a boundary layer over a permeable surface through which the fluid is withdrawn at a known rate of suction. This rate of suction is assumed, in accordance with the hypotheses of the boundary layer, to be small compared with the stream velocity, and of order $R^{-1/2}$, where R is the Reynolds number. It is supposed here that the suction is relatively large, though still of the same order. Part I deals with the similar solutions of the boundary-layer equations, part II with an arbitrary pressure distribution but constant suction velocity, and part III with the general problem.

Aeronautical Research Council (Gt. Brit.)
SANDWICH CONSTRUCTION AND CORE MATERIALS. PART IV. Section I: 'BALSOLITE' IMPREGNATED PAPER CELLULAR MATERIAL AS AN ELASTIC STABILISER. W. J. Pullen. Section II: COMPRESSION TESTS ON SANDWICH PANELS WITH 'BALSOLITE' CORES. R. G. Chapman and S. Pearson. Section III: STRENGTH TESTS OF A TYPHOON TYPE FUSELAGE OF 'BALSOLITE' SANDWICH CONSTRUCTION. J. K. Oaks. 1952. 18p. diagrs., photos., 5 tabs. (ARC R & M 2687; 10,212. Formerly ARC 7267; Strut 746; Plas. 45; RAE SME 268; RAE Test Note 122)

A range of struts each consisting of "Balsolite" filler sandwiched between two faces of 1/16-inch thick birch plywood has been tested in order to assess the efficiency of Balsolite as a stabilizer in sandwich structures. It is concluded that this material compares favorably with other low density materials when used as a stabilizer. Modification of the material, namely the use of transverse and longitudinal tubes alternately, does not appear to be beneficial.

Aeronautical Research Council (Gt. Brit.)
SOME INVESTIGATIONS ON THIN NOSE-SUCTION AEROFOILS. J. Williams. Part I: A COMPARISON OF THE STALLING PROPERTIES OF SOME THIN NOSE-SUCTION AEROFOILS. Part II: A THEORETICAL INVESTIGATION ON THIN HIGH-LIFT AEROFOILS SPECIALLY DESIGNED FOR NOSE-SLOT SUCTION. 1952. 28p. diagrs., 10 tabs. (ARC R & M 2693. Formerly ARC 11,560; Perf. 455; FM 1255; ARC 12,144; Perf. 528; FM 1334; ARC 13,090)

In part I, the experimental results from stalling tests on thin nose-suction airfoils are compared and the design features of the tested airfoils are analyzed. The airfoils include the 8-percent-thick Lighthill and Glauert sections specially designed for nose-slot suction, the 8-percent-thick H. S. A. V section with distributed suction through a porous nose, and some conventional sections of moderate thickness tested in Germany with slot suction at various positions on the nose. Part II describes a theoretical exploration of possible thin nose-slot

airfoils specially designed to have an abrupt fall in velocity where suction is to be applied on the upper surface of the nose.

Aeronautical Research Council (Gt. Brit.)
TANK TESTS ON A JET-PROPELLED BOAT-SEAPLANE FIGHTER (SAUNDERS-ROE E6/44). G. L. Fletcher. 1952. 31p. photos., diagrs., 6 tabs. (ARC R & M 2718; ARC 9404. Formerly RAE Aero 2106)

Investigations into porpoising stability, water resistance, and seaworthiness have been made on the hull design of the E6/44. The original lines were unsatisfactory for seaworthiness and porpoising stability at overload and modifications to improve these qualities have been made. Results on the final lines indicate that porpoising stability should be adequate at all loads up to the design overload, and take-off time should be well within the specified limit. Seaworthiness tests show that the limiting condition for satisfactory operation at normal load is a 2-foot sea. The hump spray is severe and, due to likelihood of damage, full advantage of flaps may not be gained unless a preselector control is used.

Aeronautical Research Council (Gt. Brit.)
FLUTTER AND DIVERGENCE OF SWEPT-BACK AND SWEPT-FORWARD WINGS. A. W. Babister. 1953. 13p. diagrs. (ARC R & M 2761; ARC 13,391. Formerly College of Aeronautics, Cranfield, Rept. 39)

In this note, the equations of the flexural-torsional flutter of a swept wing are established, assuming the wing to be semirigid and fixed at the root. The general effects of sweepback, wing stiffness, and position of the inertia axis are determined. The critical speeds for flutter and for wing divergence are determined (1) for incompressible flow and (2) for compressible flow, applying the Glauert correction. The critical flutter speed is, in general, higher for a sweptback wing having the same wing stiffness as the unswept wing; for a sweptforward wing, divergence will occur before flutter.

A METHOD OF PERFORMANCE REDUCTION FOR HELICOPTERS. F. O'Hara. 1952. 12p. diagrs. (ARC R & M 2770; ARC 11,062. Formerly AFEE Res. 26)

The equations for helicopter performance are derived in a form suitable for the development of performance reduction methods, and the equations obtained provide also a simple method of performance estimation. Formulas are determined for reducing observed performance data to standard temperature conditions and for estimating the effect of weight changes on performance. Charts of the relationships are given for typical values of helicopter and engine characteristics. The general equations are divided into two groups dealing, respectively, with forward and vertical flight. Performance reduction methods are then outlined for the three cases of climbing, level, and vertical flight and are applied to show the effect of weight changes in each case.

Ministry of Supply (Gt. Brit.)
A GRAPHICAL METHOD FOR THE RAPID ESTIMATION OF HELICOPTER PERFORMANCE. A. Armitage. January 1953. 25p. diagrs. (Ministry of Supply. RD(H)/F. 20/1)

A method of rapid estimation of helicopter flight performance is presented, with nomographic charts which save much time in calculation, for example, up to 75 percent of that taken by other current methods. The method is based on familiar helicopter theory, and was originally evolved by Capt. R. N. Liptrot when head of the department. It has now been revised and extended to cover such aspects as vertical rate of climb, and tip stall at high forward speed. The working charts have also been prepared and are included. The charts are particularly useful in rapid assessment of the worth of new projects, and in estimating the effect of varying one or more design parameters of both new and existing designs. Only standard parameters and three special factors are employed. The method compares favorably with other accepted methods. A specimen calculation performed on an actual helicopter, together with the comparable flight test values, is included as an appendix.

National Gas Turbine Establishment (Gt. Brit.)
CONVECTIVE HEAT TRANSFER IN A VORTEX CHAMBER. D. G. H. Higgins. December 1952. 24p. diagrs. (NGTE R. 127)

This report describes convective heat-transfer measurements made on a parallel walled "cyclone" vortex chamber, embracing the variables of chamber size, mass flow, inlet temperature, and inlet velocity, and establishes a correlation between Nusselt number and Reynolds number for that portion of the vortex flow unaffected by inlet and outlet

conditions, from which heat-transfer coefficients between gas and wall may be estimated. A curve is given showing the effect of inlet and outlet conditions on this correlation and suggested methods of computing the heat-transfer coefficients in these regions are included. The coefficients so obtained are for the convective component of heat transfer only, radiation effects being neglected in the tests since no combustion of fuel took place within the test chamber itself.

A PULSE-OPERATED AUTO-CORRELATOR. F. W. Stoneman. December 1952. 18p. diagrs. (RAE Tech. Note GW 225)

A pulse-operated auto-correlator offers advantages over other forms of correlator in its comparative simplicity and its ability, under certain conditions of use, to provide a complete correlogram without the necessity of recording the input data. The system involves the storage of information on a series of condensers connected to the contact banks of two uniselectors, the wipers of which can be rotated at the same speed but with any desired angular separation, equivalent to the required values of τ, the correlation interval. Theoretically the results obtained are accurate for a repetitive function if the sampling rate is more than twice the highest frequency component. A test instrument has been built which demonstrates that the principle is sound, and provides the basis of a practical machine. The main difficulties requiring further investigation are listed in the conclusions.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) GROUND POWER CHECKING OF HELICOPTER ENGINES. TESTS WITH A HOVERFLY 1. D. A. Wilkinson. August 29, 1952. 12p. photos., diagrs., tab. (AAEE/Res/268)

A preliminary investigation has been made on a Hoverfly 1 of the possibility of ground checking the power of helicopter engines. Tests have been made with both standard blades and blades fitted with attachments. These tests confirm that power checks which involve tethering are unsatisfactory and indicate that power checks should be made under low lift conditions. Two methods of achieving this condition were investigated, one using lift spoilers at high pitch, and the other using drag plates at low pitch. The latter method proved to be the more satisfactory and appears to provide a practical solution, without undue handling problems, by which power variations of the order of 2 percent could be detected. This method may be suitable for use by qualified ground crew provided that precautions are are taken to prevent the occurrence of dangerous blade motions.

THE SOURCE DISTRIBUTION REPRESENTING SUPERSONIC FLOW PAST SLENDER BODIES OF REVOLUTION HAVING DISCONTINUITIES IN THE BOUNDARY GRADIENT. L. J. Morton. November 21, 1951. 14p. diagrs. (ARC 14, 436; FM 1633)

The distribution of source strength along the axis, based on the linearized equation, which represents supersonic flow over a body of revolution is determined for a body having a discontinuity in the boundary gradient. The method consists of a step-by-step process which is applicable when the shape of the boundary is not easily expressible in an analytical form, and formulas are given for the velocity components and change in pressure at the discontinuity.

A SIMPLE AND ACCURATE METHOD FOR COMPARING MANOMETERS. J. H. Preston. June 8, 1951. 7p. diagr. (ARC 14, 072; TP 340)

It is shown that the simple device of a water-sealed reservoir enables a constant pressure difference to be applied to the manometers under comparison. Effects due to temperature changes in the reservoir and the interaction of the adjustment of one manometer on the indication of the other are negligible compared with the observed effects when a completely closed reservoir is used. A theoretical explanation of this is given. The readings of two manometers can be compared with an accuracy which is limited only by the sensitivity of the manometers and the amount of zero creep due to room temperature changes.

EXPERIMENTS ON TWO-DIMENSIONAL SUPERSONIC FLOW IN CORNERS AND OVER CONCAVE SURFACES. N. H. Johannesen. January 29, 1952. 20p. diagrs., photos. (ARC 14, 607; FM 1669)

Two simple cases of two-dimensional supersonic flow were investigated by schlieren photography, namely the flow in two consecutive corners and the flow over a circular-arc profile concave to the stream. The flows were photographed for smooth and rough surfaces of the models, that is, with laminar and turbulent boundary layers, and the observed flow patterns are compared with those predicted by inviscid theory. The flow with a turbulent boundary layer was in good agreement with inviscid theory outside the boundary layer, whereas the laminar boundary layer separated and a shock wave originated at the point of separation. In both cases, the agreement was good at points far from the surface. A discussion is given of the flow at the point of intersection of three shock waves, and of a shock wave and a centered compression. For the latter case, photographs show a weak shock wave in the direction of the downstream Mach line at the point of intersection.

Aeronautical Research Council (Gt. Brit.)
THE FLOW IN THE THREAT OF A SUPERSONIC EFFUSER. W. F. Cope and R. O. Gibson. August 23, 1951. 10p. diagrs. (ARC 14,214; FM 1595)

The velocity profiles have been calculated for two radii of curvature and two values of γ for each radius. They are considerably affected by the radius and hardly at all by γ. Comparison with Hermann's results suggests that his "X shocks" may be a supersaturation phenomenon. It is proposed to calculate the flow further down the effuser by including more terms of the series for the velocity potential and using a boundary curve which has a point of inflection.

CURRENT NACA REPORTS

NACA Rept. 1074

HYDRODYNAMIC IMPACT OF A SYSTEM WITH A SINGLE ELASTIC MODE. I - THEORY AND GENERALIZED SOLUTION WITH AN APPLICATION TO AN ELASTIC AIRFRAME. Wilbur L. Mayo. 1952. ii, 17p. diagrs., 2 tabs. (NACA Rept. 1074. Formerly TN 1398)

Solutions of impact of a rigid prismatic float connected by a massless spring to a rigid upper mass are presented. The solutions are based on hydrodynamic theory which has been experimentally confirmed for a rigid structure. Equations are given for defining the spring constant and the ratio of the sprung mass to the lower mass so that the two-mass system provides representation of the fundamental mode of an airplane wing. The forces calculated are more accurate than the forces which would be predicted for a rigid airframe since the effect of the fundamental mode on the hydrodynamic force is taken into account. The response of the two-mass system gives the response of the represented mode and, although no provision is made for taking into account the effect of secondary modes on the hydrodynamic force, means are indicated whereby the results may be used to approximate the response of modes other than the fundamental mode.

NACA Rept. 1076

EFFECTS ON LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A BOEING B-29 AIRPLANE OF VARIATIONS IN STICK-FORCE AND CONTROL-RATE CHARACTERISTICS OBTAINED THROUGH USE OF A BOOSTER IN THE ELEVATOR-CONTROL SYSTEM. Charles W. Mathews, Donald B. Talmage and James B. Whitten. 1952. ii, 17p. diagrs., photo., tab. (NACA Rept. 1076. Formerly TN 2238; RM L50D11)

The longitudinal stability and control characteristics of a B-29 airplane have been measured with a control surface booster incorporated in the elevator-control system. The measurements were obtained with the booster operating to provide various control-force gradients and various maximum rates of control motion. Results are presented which show the effect of these booster parameters on the handling qualities of the test airplane.

NACA Rept. 1087

INTERNAL-LIQUID-FILM-COOLING EXPERIMENTS WITH AIRSTREAM TEMPERATURES TO 2000° F IN 2- AND 4-INCH-DIAMETER HORIZONTAL TUBES. George R. Kinney, Andrew E. Abramson and John L. Sloop. 1952. ii, 21p. diagrs., photos., 5 tabs. (NACA Rept. 1087. Formerly RM E50F19; RM E51C13; RM E52B20)

An experimental investigation of internal-liquid-film cooling was conducted in 2- and 4-inch-diameter straight metal tubes with air flows at 600° to 2000° F and Reynolds numbers from 2.2 to 14 x 10^5. The coolant was water at flows of 0.8 to 12 percent of air flow. Visual observations of liquid-film flows were made in transparent tubes with air flows at 80° and 800° F and diameter Reynolds numbers from 4.1 to 29 x 10^5. Flows of water, water-detergent solutions, and aqueous ethylene glycol solutions were investigated. Liquid-coolant films were established and maintained around and along the tube wall in concurrent flow with the hot air. The tube wall was kept below the boiling temperature of the coolant over the surfaces covered by liquid coolant. Coolant films were relatively smooth unless the coolant flow was sufficiently high so that the liquid film was thick enough to enter the region where turbulent forces predominate over viscous forces; wavelike disturbances then developed on the liquid film. These disturbances resulted in increased loss of coolant from the film and reduced effectiveness of the coolant.

NACA Rept. 1093

HEAT TRANSFER TO BODIES IN A HIGH-SPEED RAREFIED-GAS STREAM. Jackson R. Stalder, Glen Goodwin and Marcus O. Creager. 1952. ii, 10p. diagrs., tab. (NACA Rept. 1093. Formerly TN 2438)

The equilibrium temperature and heat-transfer coefficients for transverse cylinders in a high-speed stream of rarefied gas were measured over a range of Knudsen numbers from 0.025 to 11.8 for Mach numbers from 2.0 to 3.3. Fully developed free-molecule flow was found to first occur at Knudsen numbers of approximately 2.0. The Nusselt number was found to be a function of the Reynolds number only, and the temperature-recovery factor to depend primarily on the Knudsen number.

NACA TN 2908

DETERMINATION OF MEAN CAMBER SURFACES FOR WINGS HAVING UNIFORM CHORDWISE LOADING AND ARBITRARY SPANWISE LOADING IN SUBSONIC FLOW. S. Katzoff, M. Frances Faison and Hugh C. DuBose. May 1953. 43p. diagrs., tab. (NACA TN 2908)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

Methods involving integrations around the wing boundary are presented for computing mean camber surfaces to support uniform chordwise loading, with either uniform or nonuniform spanwise loading, in subsonic flow. For polygonal wings with uniform area loading, analytical expressions are developed for both the slopes and the ordinates of the mean camber surfaces. Mean camber surfaces of several calculated wings are shown.

NACA TN 2924

COMBINED-STRESS FATIGUE STRENGTH OF 76S-T61 ALUMINUM ALLOY WITH SUPERIMPOSED MEAN STRESSES AND CORRECTIONS FOR YIELDING. William N. Findley, University of Illinois. May 1953. 90p. diagrs., photos., 3 tabs. (NACA TN 2924)

Fatigue data for 76S-T61 aluminum alloy are presented for several combinations of bending and torsion with both alternating and mean stresses. Special fatigue equipment for these tests is described. Correction for yielding was applied to the mean stresses in the bending and in the torsion fatigue tests. The literature on the effect of combined stress and of mean stress in fatigue is reviewed and the results of the present series are compared with those of various theories. A new notation for state of stress and a new criterion for combined stress fatigue are discussed. A correction for anisotropy is proposed and its effect discussed. Energy theories of fatigue under combined stress are critically examined and a test proposed. The observed mode of fracturing is described and a qualitative theory of the mechanism of formation and propagation of fatigue cracks is proposed.

NACA TN 2930

STRENGTH ANALYSIS OF STIFFENED THICK BEAM WEBS WITH RATIOS OF WEB DEPTH TO WEB THICKNESS OF APPROXIMATELY 60. L. Ross Levin. May 1953. 11p. photo., diagrs., 2 tabs. (NACA TN 2930)

The results of an experimental investigation of the strength of plane diagonal-tension webs with ratios of web depth to web thickness of about 60 are presented. An analysis of the beams indicated that the methods of strength analysis presented in NACA TN 2661 are applicable to beams with the flanges symmetrically arranged with respect to the web if the portal-frame effect is taken into account.

NACA TN 2935

THE GALVANIC CORROSION THEORY FOR ADHERENCE OF PORCELAIN-ENAMEL GROUND COATS TO STEEL. D. G. Moore, J. W. Pitts, J. C. Richmond and W. N. Harrison, National Bureau of Standards. June 1953. 19p. diagrs., photos. (NACA TN 2935)

The galvanic corrosion theory of adherence between ground-coat enamels and steel was investigated. The theory, which is based on mechanical anchoring of the enamel into pits formed by galvanic attack of the enamel on the steel, was first examined from the standpoint of data on adherence obtained in earlier studies. Also, several experiments were performed which demonstrated that galvanic corrosion could occur during the short firing times encountered in enamel processing. However, inconsistencies were observed in the data which indicated that the mechanism of galvanic attack followed by mechanical anchoring was not the only important factor affecting bond strength.

NACA TN 2941

THE DRAG OF FINITE-LENGTH CYLINDERS DETERMINED FROM FLIGHT TESTS AT HIGH REYNOLDS NUMBERS FOR A MACH NUMBER RANGE FROM 0.5 TO 1.3. Clement J. Welsh. June 1953. 12p. diagrs., photo. (NACA TN 2941. Formerly RM L52C31)

Results of a free-flight investigation to determine the drag of circular, finite-length cylinders are presented for a Mach number range from about 0.5 to 1.3. Also included are drag results of previous experimental tests of infinite-length cylinders. Drag of circular cylinders at supersonic speeds is largely independent of fineness ratio and Reynolds number; whereas, at subsonic speeds, the drag of finite-length cylinders (fineness ratios of about 60 and below) increases as their fineness ratios increase.

NACA TN 2942

PRESSURE DISTRIBUTIONS ABOUT FINITE WEDGES IN BOUNDED AND UNBOUNDED SUBSONIC STREAMS. Patrick L. Donoughe and Ernst I. Prasse. May 1953. 41p. diagrs., photos., 2 tabs. (NACA TN 2942)

An analytical investigation of incompressible flow about wedges was made to determine effects of tunnel-wedge ratio and wedge angle on the wedge pressure distributions. The region of applicability of infinite wedge-type velocity distribution was examined for finite wedges. Theoretical and experimental pressure coefficients for various tunnel-wedge ratios, wedge angles, and subsonic Mach numbers were compared.

NACA TN 2943

THE ATTENUATION CHARACTERISTICS OF FOUR SPECIALLY DESIGNED MUFFLERS TESTED ON A PRACTICAL ENGINE SETUP. George M. Stokes and Don D. Davis, Jr. May 1953. 30p. diagrs., photos., tab. (NACA TN 2943)

Attenuation characteristics of four different resonator mufflers were determined in both cold tests and engine field tests and compared with the theoretical calculations. These mufflers were specifically designed for a helicopter. Engine-exhaust sound pressures, temperatures, and noise levels from the helicopter were measured. The experimental muffler cold tests indicated close a agreement with theory, whereas the engine tests

indicated some discrepancies. Test results show the usefulness of the theoretical equation used for predicting muffler attenuation characteristics.

NACA TN 2945

THE CREEP OF SINGLE CRYSTALS OF ALUMINUM. R. D. Johnson, F. R. Shober and A. D. Schwope, Battelle Memorial Institute. May 1953. 51p. diagrs., photos., tab. (NACA TN 2945)

The creep of single crystals of high-purity aluminum was investigated in the range of temperatures from room temperature to 400° F and at resolved-shear-stress levels of 200, 300, and 400 psi. The tests were designed in an attempt to produce data regarding the relation between the rate of strain and the mechanism of deformation. The creep data are analyzed in terms of shear strain rate and the results are discussed with regard to existing creep theories. Stress-strain curves were determined for the crystals in tensil and constant-load-rate tests in the same temperature range to supplement the study of plastic deformation by creep with information regarding the part played by crystal orientation, differences in strain markings, and other variables in plastic deformation.

NACA TN 2946

A SMALL PIRANI GAGE FOR MEASUREMENTS OF NONSTEADY LOW PRESSURES. M. John Pilny. June 1953. i, 36p. diagrs., photos. (NACA TN 2946)

A small Pirani gage made of surgical grain-of-wheat lamps and its operating equipment for the measurement of 12 channels of low pressures in the range 0.1 to 10 mm Hg abs are described, together with techniques of calibration and use. Theoretical and measured characteristics of small Pirani gages are presented to show the suitability of such gages for the precise measurement of nonsteady low pressures.

NACA TN 2947

A VISUALIZATION STUDY OF SECONDARY FLOWS IN CASCADES. Arthur G. Hansen, Howard Z. Herzig and George R. Costello. May 1953. 93p. photos., diagrs. (NACA TN 2947. Formerly RM E52F19)

Flow-visualization techniques are employed to ascertain the streamline patterns of the nonpotential, secondary flows in the boundary layers of cascades, thereby providing a basis for more extended analyses in turbomachines. The three-dimensional deflection of the end-wall boundary layer results in the formation of a vortex well up in each cascade passage. The size and tightness of the vortex generated depend upon the main flow turning in the cascade passage. Once formed, a vortex resists turning in subsequent blade rows. This results in unfavorable angles of attack and possible flow disturbances on the pressure surfaces of subsequent blade rows when the vortices impinge on these surfaces. Two major tip-clearance effects are observed: the formation of a tip-clearance vortex, and the scraping effect of a blade with relative motion past the wall boundary layer. The flow patterns indicate methods for improving the blade-tip loading characteristics of compressors and of low- and high-speed turbines.

NACA TN 2949

A VARIABLE-FREQUENCY LIGHT SYNCHRONIZED WITH A HIGH-SPEED MOTION-PICTURE CAMERA TO PROVIDE VERY SHORT EXPOSURE TIMES. Walter F. Lindsey and Joseph Burlock. May 1953. 17p. photos., diagrs. (NACA TN 2949)

A new high-speed photographic technique has been developed which employs a variable-frequency light synchronized with a commercially available 16-millimeter high-speed motion-picture camera without appreciable alterations to the camera. The technique is described and results obtained by this technique of photographing the flow past models in a wind tunnel employing the schlieren method of flow visualization are presented. The photographs show that the new technique, through the use of extremely short exposure times (about 4 microseconds), provides more sharply defined pictures throughout the flow field than were obtained by conventional techniques.

NACA TN 2950

A NEW SHADOWGRAPH TECHNIQUE FOR OBSERVATION OF CONICAL FLOW PHENOMENA IN SUPERSONIC FLOW AND PRELIMINARY RESULTS OBTAINED FOR A TRIANGULAR WING. Eugene S. Love and Carl E. Grigsby. May 1953. 16p. diagrs., photos. (NACA TN 2950)

A new shadowgraph technique is presented for the observation of conical flow phenomena in supersonic flow in a plane normal or nearly normal to the axis of propagation. Preliminary results obtained for a triangular wing are also presented.

NACA TN 2951

FLIGHT INVESTIGATION OF THE EFFECT OF TRANSIENT WING RESPONSE ON WING STRAINS OF A FOUR-ENGINE BOMBER AIRPLANE IN ROUGH AIR. Harold N. Murrow and Chester B. Payne. June 1953. 24p. diagrs., 2 tabs. (NACA TN 2951)

The results of a flight investigation on a four-engine bomber airplane to determine the effect of wing flexibility on wing strains show that the average amplification at the wing root station for bending strains per g in gusts was approximately 31 percent higher than the bending strains per g in slow pull-ups. The amplification factor decreased in the outboard direction, except for the most outboard station where it increased slightly. At the inboard stations the vibratory inertia effects on spar shear strains appear to induce the primary strains. At

the outboard stations the amplification factors for the shear strains were approximately the same as those for the bending strains.

NACA TN 2952

IMPINGEMENT OF WATER DROPLETS ON NACA 65_1-208 AND 65_1-212 AIRFOILS AT 4° ANGLE OF ATTACK. Rinaldo J. Brun, Helen M. Gallagher and Dorothea E. Vogt. May 1953. 49p. diagrs. (NACA TN 2952)

The trajectories of droplets in the air flowing past an NACA 65_1-208 airfoil and an NACA 65_1-212 airfoil, both at an angle of attack of 4°, were computed with a mechanical analog. The amount of water in droplet form impinging on the airfoils, the area of droplet impingement, and the rate of droplet impingement per unit area on the airfoil surface affected were calculated from the trajectories.

NACA TN 2953

AN INVESTIGATION OF THE EXPERIMENTAL AERODYNAMIC LOADING ON A MODEL HELICOPTER ROTOR BLADE. John R. Meyer, Jr. and Gaetano Falabella, Jr., Massachusetts Institute of Technology. May 1953. 110p. diagrs., photos. (NACA TN 2953)

Pressure distributions were measured on a model helicopter rotor blade under hovering and simulated forward-flight conditions. Pressures were recorded at advance ratios of 0.10, 0.22, 0.30, 0.40, and 0.50 for a zero-offset flapping-hinge rotor and at 0.10, 0.22, 0.30, 0.45, 0.60, 0.80, and 1.0 for a lifting rotor having a flapping-hinge offset of 13 percent. Analysis of angle of attack at the tip of the retreating blade indicated that an appreciable offset flapping hinge in combination with a low blade mass constant offers a means of postponing stall on the retreating blade.

NACA RM 53D14

EFFECTS OF HIGH DEGREES OF BIAXIAL STRETCH-FORMING ON CRAZING AND OTHER PROPERTIES OF ACRYLIC PLASTIC GLAZING. I. Wolock, B. M. Axilrod and M. A. Sherman. National Bureau of Standards. May 1953. 19p. photos., diagrs., 3 tabs. (NACA RM 53D14)

Tests were conducted on sheets of commercial cast polymethyl methacrylate that were hot-stretched approximately 100 and 150 percent and on unstretched control material. Tensile strength increased only for the 150-percent-stretched material. Total elongation was higher for the stretched materials than for the unstretched but decreased as the degree of stretching increased. None of the stretched specimens crazed in the short-time tensile tests. The threshold stress for stress-solvent crazing with benzene increased from approximately one-fourth of the ultimate strength for the unstretched material to approximately three-fourths for the 100-percent-stretched material. Most of the 150-percent-stretched specimens did not solvent craze at stresses very close to the ultimate strength. Abrasion resistance of the stretched material was appreciably less than that of the unstretched material.

NACA RM E53C26

DE-ICING AND RUNBACK CHARACTERISTICS OF THREE CYCLIC, ELECTRIC, EXTERNAL DE-ICING BOOTS EMPLOYING CHORDWISE SHEDDING. Robert S. Ruggeri. May 1953. 32p. photos., diagrs. (NACA RM E53C26)

The performance characteristics of three cyclic, electric, rubber-clad de-icing boots were evaluated. Each boot was operated in icing at design specifications of 21 watts per square inch for cycled areas, 13 watts per square inch for continuously heated parting strips, a heat-on time of 10 seconds, and a cycle ratio of 10. For a free-stream velocity of approximately 395 feet per second, the range of free-stream total temperature at which the icing protection afforded by the various boots became marginal was from 12° to 15° F for values of liquid-water content employed. The runback characteristics of the boots were similar. The forward cycled segments, upper and lower surfaces, were the most critical areas for the three boots investigated.

NACA RM L53A30

GUST-TUNNEL INVESTIGATION TO DETERMINE EFFECTS OF CENTER-OF-GRAVITY POSITION ON THE GUST LOADS OF A DELTA-WING MODEL WITH LEADING EDGE SWEPT BACK 60°. Thomas D. Reisert and Domenic J. Maglieri. June 1953. 13p. diagrs., photo., 2 tabs. (NACA RM L53A30)

A gust-tunnel investigation to determine the effect of center-of-gravity position on the gust loads on a delta-wing model with the leading edge swept back 60° was made over a range of center-of-gravity positions from 4 percent ahead of to 11 percent behind the leading edge of the mean geometric chord. This investigation indicated that a 1-percent rearward movement of the center-of-gravity position increased the acceleration increment in the sharp-edge gust by 0.5 percent. In a gust with a gradient distance of 6.5 chords, the acceleration increment was increased by approximately 2 percent for the same movement of the center of gravity. Comparison of these results with those for a conventional airplane model indicates that the change in load for both configurations would be nearly the same in a sharp-edge gust, but in a gust with a gradient distance of 6.5 chords, the change in load for a given change in center-of-gravity position would be approximately twice as great for the delta-wing model as for the conventional airplane model.

NACA TM 1350

THE MICROSTRUCTURE OF TURBULENT FLOW. (Mikrostructura turbulentnogo potoka.) A. M. Obukhoff and A. M. Yaglom. June 1953. 41p. diagrs. (NACA TM 1350. Trans. from Prikladnaya Matematika i Mekhanika, v. 15, 1951, p. 3-26).

An attempt is made to describe quantitatively the structure of the velocity, pressure, and acceleration fields for all scales for which the theory of Kolmogoroff is applicable.

BRITISH REPORTS

Aeronautical Research Council (Gt. Brit.)
THE METHOD OF INFLUENCE FACTORS IN ARITHMETICAL SOLUTIONS OF CERTAIN FIELD PROBLEMS. PART I. A. Thom. PART II. Laura Klanfer. 1953. 30p. diagrs., tab. (ARC R & M 2440. Formerly ARC 9854; FM 968; ARC 11,010; FM 968a)

This paper gives an extension to the squares method of solving certain field problems. The idea of influence factors is used. This enables certain problems to be solved without squaring and reduces the actual arithmetical work in others to a fraction of that otherwise required. As an example, the effect of the channel walls is calculated for the flow of a compressible fluid past given profiles in channels of different widths. A comparison is also made of the resulting blockage factor with the values given by the mass-flow method described in previous work.

N-21802*

Aeronautical Research Council (Gt. Brit.)
TRANSITION AND DRAG MEASUREMENTS ON THE BOULTON PAUL SAMPLE OF LAMINAR-FLOW WING CONSTRUCTION. Part I: MEASUREMENTS IN THE 13 x 9 FT TUNNEL AT THE N. P. L. J. H. Preston and N. Gregory. Part II: MEASUREMENTS IN THE NO. 2, $11\frac{1}{2}$-FT TUNNEL AT THE R. A. E. K. W. Kimber. Part III: DISCUSSION OF RESULTS, AND NOTE. J. H. Preston. 1952. 23p. photos., diagrs., tab. (ARC R & M 2499; ARC 10,123. Formerly RAE Aero 2170)

Transition tests and drag measurements have been carried out on the Boulton Paul sample of laminar-flow wing construction up to $R = 9 \times 10^6$ in the National Physical Laboratory 13- by 9-foot tunnel and in the Royal Aircraft Establishment 11-1/2 by 8-1/2 foot tunnel up to $R = 15 \times 10^6$. At small incidences lying between $\pm 2^\circ$ and at Reynolds numbers up to 9×10^6, the agreement between measurements made in both tunnels is good. At incidences of $\pm 3^\circ$ and $\pm 4^\circ$ the transition moves forward with increase of speed more rapidly in the R. A. E. tunnel than in the N. P. L. tunnel, and the transition front is considerably more irregular in the R. A. E. tunnel. This difference occurs in spite of the appreciably less measured turbulence of the R. A. E. tunnel, which may be expected to show up, on a wing with appreciable waviness, near the limit of the low-drag range. In the N. P. L. tunnel the theoretical low-drag C_L range of ± 0.35 is maintained up to about $R = 7 \times 10^6$ with transition back to beyond 0.4c (pressure minimum at 0.45c). In the R. A. E. tunnel, the corresponding R is slightly less. The low-drag range decreases as R is increased until, at $R = 15 \times 10^6$ in the R. A. E. tunnel, the low-drag range of incidence is only $\pm 1^\circ$. This reduction is attributed to waviness of the model, exaggerated by the turbulence of the tunnel stream. Nevertheless the wing, considering its waviness, has performed remarkably well in both tunnels, especially when compared with previous models of lower waviness.

SOME EXPERIMENTS ON THE HEAT TRANSFER FROM A GAS FLOWING THROUGH A CONVERGENT-DIVERGENT NOZZLE. O. A. Saunders and P. H. Calder. January 5, 1952. 13p. diagrs., 2 tabs. (ARC 14,539; R. 222)

Heat transfer at high subsonic and supersonic speeds is more complicated than at normal velocities because the cross-sectional temperature distribution is not usually fully developed. The central core of gas is often unaffected by the heat added, in contrast to one-dimensional flow calculations which assume the heat to be spread over the whole cross section. Experiments are described using a water-cooled convergent divergent nozzle of smooth continuous profile through which hot gases at 865° C were passed and the heat transfer measured at different positions along the divergent portion, at Mach numbers up to 1.75. The results are very consistent when plotted in terms of the length Reynolds number measured from the throat. Velocity traverses at the exit also confirm that the boundary layer may be assumed to be turbulent and to commence at the throat. The heat-transfer results also agree very well with the formulas for turbulent flow over a flat plate at low speeds, suggesting that such low speed formulas may be used for supersonic flow in nozzles. Some tests with a straight pipe at high subsonic speeds give results somewhat higher than the flat plate formula, due probably to pipe radius effects.

THE TURBULENT BOUNDARY LAYER IN DIFFUSING DUCTS. (Abbreviated thesis) R. R. Shaw. January 17, 1952. 42p. diagrs., tabs. (ARC 14,587; FM 1667; Oxford Univ., Engineering Lab. No. 57)

The work reported in this thesis has been primarily a study of the flow in the (turbulent) boundary layer, but with particular emphasis on those aspects of this subject which are pertinent to calculations in a conical diffuser, and the thesis concludes with the application of the results obtained to a few typical calculations on a diffuser. The work has been restricted to the cone of an incompressible fluid, and to the turbulent (as distinct from the laminar) boundary layer.

THE BURNING OF SINGLE DROPS OF FUEL. Part V. THE COMBUSTION RATES OF SOLID FUEL PARTICLES. G. A. E. Godsave. November 1952. 35p. diagrs., 5 tabs. (NGTE R. 126)

A method of calculating the burning rates of solid spherical particles is proposed, using as a basis Frössling's semiempirical equation for the transfer of mass in the neighborhood of spherical surfaces. The theoretical treatment shows good agreement with published experimental results on the burning rates of carbon spheres. This being so, the theoretical equation may be used to calculate in particular the effects of Reynolds number and partial pressure of oxygen on the combustion rates.

OUTLINED GENERAL TREATMENT OF THE CALCULATION OF WAVE EFFECTS DUE TO SMALL DISTURBANCES OF STEADY STABILISED BURNING. PART I. P. W. H. Howe. November 1952. 51p. diagrs. (NGTE R. 128)

A procedure is outlined for calculating the transient effects caused by typical disturbances of steady burning conditions, in a duct employing a stabilized flame and a fuel with any burning characteristics. The method of solution is to express the available information as analytical formulas applying to simple cases, and then to build up an iterative process using the simple cases.

SOME CURVES FOR USE IN CALCULATIONS OF THE PERFORMANCE OF CONICAL CENTREBODY INTAKES AT SUPERSONIC SPEEDS AND AT FULL MASS FLOW. L. E. Fraenkel. 1953. 33p. diagrs., 2 tabs. (ARC CP 108)

This note presents curves of a number of parameters which frequently occur in calculations of the performance of conical centerbody intakes at supersonic speeds and full mass flow. These parameters follow directly from the theoretical supersonic flow past cones. Semicone angles of 15°, 20°, 22.5°, 25°, and 30° are considered, and the range of free stream Mach number is approximately 1.3 to 3.0.

THE PRESSURE ON THE SURFACE OF A FLAT ELLIPTIC CONE SET SYMMETRICALLY IN A SUPERSONIC STREAM. D. G. Hurley. 1953. 18p. diagrs., tab. (ARC CP 109)

The first order solution of the problem of the supersonic flow past a flat elliptic cone set symmetrically to the wind indicates that the pressure over the surface is constant if the body lies within the Mach cone of the apex. This result is incorrect near the leading edges of the cone and an improved solution is derived here by the introduction of line sources near the leading edges. Numerical results are given for three bodies.

LOW SPEED WIND TUNNEL INVESTIGATION OF TAB HINGE MOMENT CHARACTERISTICS. W. J. G. Trebble and J. F. Holford. 1953. 20p. diagrs., 4 tabs. (ARC CP 112)

Hinge moments have been measured on tabs of 4.7-percent local chord on a tailplane with 14° trailing-edge angle. The range of investigation covered the effects of 32-percent nose balance and of the gap between tab and elevator. For small deflections of the control surfaces c_1 and c_2 are negligible while c_3 is -0.36 and -0.28 for the unbalanced and balanced tabs, respectively. With large angles of

the elevator, and with moderate angles when the elevator gap is open, c_2 tends to the calculated value for this wing without boundary-layer terms. Consequently the curve of tab hinge moment as the tab and elevator both move is not linear. Values of c_1 and c_3 calculated by thick airfoil theory, with Bryant's empirical boundary-layer terms, are in good agreement with measured values for small deflections.

AN APPROXIMATE METHOD OF DERIVING THE TRANSIENT RESPONSE OF A LINEAR SYSTEM FROM THE FREQUENCY RESPONSE. C. A. A. Wass and E. G. Hayman. 1953. 20p. diagrs., 2 tabs. (ARC CP 113)

There are several published methods of deriving the transient response of a linear system from the known frequency response, but these are all rather lengthy. Another method is described, which is much more rapid, although less accurate. It is based on the calculation of the response of the system to a square wave as expressed by a Fourier series. For any system, there is an optimum square wave frequency, and the process of selection of this fundamental frequency is described. It is shown that consideration of responses up to the eleventh harmonic only can give transient response curves which are in error by less than 2 percent. A description is given of a circular computor which speeds the calculations, and two tables of values are included for use with the computer.

ASYMMETRIC TAILPLANE LOADS DUE TO SIDESLIP. Winfried Braun. 1953. 45p. diagrs., 2 tabs. (ARC CP 119)

A method is derived which estimates the tailplane rolling-moment coefficient due to sideslip for use in strength calculations. The investigation covers the contributions to the rolling moment from the end-plate effect at the fin (twin fins are not considered), the dihedral of the tailplane, the effect of the body (which differs on the lee and windward-sides), the effects of sweepback and plan form, and of unsymmetrical lift distribution on the main wing. An allowance is made for the influence of propeller slipstream, and a tolerance suggested to cover inaccuracies of the method. Comparison with experiment shows good agreement. The method is summarized and an example given in appendices.

A SATURABLE-CORE CURRENT REFERENCE CIRCUIT FOR USE WITH MAGNETIC AMPLIFIERS. A. G. Milnes and T. V. Vernon. October 1952. 14p. diagrs., tab. (RAE Tech. Note EL. 46)

A reliable, robust saturable-core type reference circuit suitable for use with magnetic amplifier regulators is described and its theory of operation discussed. Details are given of a practical design for 115V, 400 c/s operation with an output current of about 8 mA in a load of 60 ohms. With a ±10 percent supply voltage and ±7-1/2 percent frequency change an accuracy of better than ±1 percent may be expected during 1,000 hours for a range of ambient temperature from +15° C to +35° C. If the ambient temperature range is wide, for example the service range -65° to +70° C, rough temperature control to within ±5° C is required on two of the components to obtain the same over-all accuracy in the reference current. In the design described the reference draws a current of up to 50 mA from the 115 volt supply, excluding the oven heater load; and the over-all size of the reference circuit complete with the temperature-control oven is 3 in. x 2-1/2 in. x 4-1/4 in.

Royal Aircraft Establishment (Gt. Brit.)
ALLOYS OF TITANIUM WITH SILICON. D. A. Sutcliffe and A. C. Spickett. February 1953. 33p. diagrs., photos., 8 tabs. (RAE Met.73)

Binary titanium alloys containing up to 5.5-percent silicon by weight have been prepared by arc melting, and the limit of solid solubility of silicon in titanium determined by quenching and subsequent microscopic examination of the specimens. Tensile and hardness tests have been made on the alloys at temperatures up to 650° C and 800° C, respectively. The results show that silicon has a useful strengthening effect on titanium at elevated temperatures; 4.0-percent silicon increases the U.T.S by approximately 3 times at 650° C. Silicon also improves the oxidation resistance at 800° C and 1000° C. Limited experiments have been made to see whether the alloys were heat treatable. Some observations on the working and machining of the alloys are given.

NACA RM A8B05

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF SUPPORT INTERFERENCE ON THE DRAG OF BODIES OF REVOLUTION AT A MACH NUMBER OF 1.5. Edward W. Perkins. May 7, 1948. 50p. diagrs., phqtos. (NACA RM A8B05) (Declassified from Confidential, 4/10/53)

This report contains the results of experimental investigation to determine the effects of support interference on the base drag and fore drag of two bodies of revolution. The results show that the rear supports affect the drag of a body of revolution through the immediate influence on the pressures acting over the rear portions of the body and thus depend on the afterbody shape of the model, the Reynolds number of flow, and the condition of the boundary layer.

NACA RM A52A10

EFFECTS OF FINITE SPAN ON THE SECTION CHARACTERISTICS OF TWO 45° SWEPT-BACK WINGS OF ASPECT RATIO 6. Lynn W. Hunton. March 17, 1952. 34p. diagrs. (NACA RM A52A10) (Declassified from Restricted, 4/10/53)

A study has been made of the finite-span effects on the local loading characteristics of two sweptback wings at low speed with a view toward providing some insight into the usefulness of two-dimensional section data and span-loading theory for determining the section characteristics of a swept wing. The two wings considered were identical in plan form having 45° of sweepback of the quarter-chord line, an aspect ratio of 6, and a taper ratio of 0.5 but differed in twist and in sections, the latter being the NACA 64A010 and NACA 64A810. The analysis is based on comparisons of local pressure distributions and local lift characteristics on the wings with comparable two-dimensional section data, all of which were available at large scale.

NACA RM E8G01

PERFORMANCE OF 24-INCH SUPERSONIC AXIAL-FLOW COMPRESSOR IN AIR. II— PERFORMANCE OF COMPRESSOR ROTOR AT EQUIVALENT TIP SPEEDS FROM 800 TO 1765 FEET PER SECOND. Irving A. Johnsen, Linwood C. Wright and Melvin J. Hartmann. January 21, 1949. 31p. diagrs. (NACA RM E8G01) (Declassified from Restricted, 4/13/53)

Results are presented for an experimental supersonic axial-flow compressor over a range of equivalent tip speeds from 800 to 1765 feet per second. The necessity to establish simple radial equilibrium behind the rotor-passage-contained normal shock is pointed out. The performance is compared to that of a similar supersonic compressor previously run in Freon-12 at the NACA Langley Laboratory. The maximum pressure ratio produced in the single stage without inlet-guide vanes was 2.08 at 1765 feet per second and was obtained at an adiabatic efficiency of 0.79 and a weight flow of 64.07 pounds per second.

NACA RM E9L21

APPROXIMATE RELATIVE-TOTAL-PRESSURE LOSSES OF AN INFINITE CASCADE OF SUPERSONIC BLADES WITH FINITE LEADING-EDGE THICKNESS. John F. Klapproth. March 3, 1950. 8p. diagrs. (NACA RM E9L21) (Declassified from Restricted, 4/13/53)

By applying a hyperbolic approximation to the form of the bow waves caused by blunt leading edges on an infinite cascade of supersonic blades, the approximate losses in relative total pressure due to the external bow-wave system arising from blunt edges and subsonic axial entrance velocities were compared. The losses increase linearly with leading-edge radius for any given relative Mach number. For a relative Mach number of 1.60, leading-edge radii may be approximately 1.5 percent of the normal blade gap with a 1-percent loss of relative total pressure.

NACA RM E51H07

DISCUSSION OF BOUNDARY-LAYER CHARACTERISTICS NEAR THE CASING OF AN AXIAL-FLOW COMPRESSOR. Artur Mager, John J. Mahoney and Ray E. Budinger. December 12, 1951. 66p. diagrs., photo., tab. (NACA RM E51H07. Now Rept. 1085) (Declassified from Restricted, 4/10/53)

Boundary-layer velocity profiles on the casing of an axial-flow compressor behind the guide vanes and rotor were measured and resolved into two components: along the streamline of the flow and perpendicular to it. Boundary-layer thickness and the deflection of the boundary layer at the wall were the generalizing parameters. Use of these results and the momentum-integral equations, the characteristics of boundary layer on the walls of axial-flow compressor are qualitatively discussed. Important parameters concerning secondary flow in the boundary layer appear to be turning of the flow and the product of boundary-layer thickness and streamline curvature outside the boundary layer. Two types of separation are shown to be possible in three dimensional boundary layer.

NACA RM L8H13

THEORETICAL AND EXPERIMENTAL ANALYSIS OF LOW-DRAG SUPERSONIC INLETS HAVING A CIRCULAR CROSS SECTION AND A CENTRAL BODY AT MACH NUMBERS OF 3.30, 2.75, AND 2.45. Antonio Ferri and Louis M. Nucci. November 10, 1948. 89p. photos., diagrs. (NACA RM L8H13) (Declassified from Confidential, 4/13/53)

Contains theoretical and experimental analysis of circular inlets having a central body at Mach numbers of 3.30, 2.75, and 2.45. The inlets have been designed in order to have low drag and high pressure

recovery. The pressure recoveries obtained are of the same order of magnitude as those previously obtained by inlets having very large external drag.

NACA RM L9G06

PRELIMINARY ANALYSIS OF AXIAL-FLOW COMPRESSORS HAVING SUPERSONIC VELOCITY AT THE ENTRANCE OF THE STATOR. Antonio Ferri. September 12, 1949. 36p. diagrs. (NACA RM L9G06) (Declassified from Confidential, 4/13/53)

An analysis of the phenomena related to an axial supersonic compressor having supersonic velocity in front of the stator is presented. The analysis shows that compression ratio for stages between 6 and 10 and adiabatic efficiency between 70 and 80 percent can be obtained. Rotor and stator design are discussed on the basis of the results of supersonic cascade tests. Range of performance of the compressor, flow stability, and starting conditions are also discussed.

NACA RM L9G07

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF 90° SUPERSONIC TURNING PASSAGES SUITABLE FOR SUPERSONIC COMPRESSORS OR TURBINES. Luke L. Liccini. September 12, 1949. 91p. photos., diagrs., 3 tabs. (NACA RM L9G07) (Declassified from Confidential, 4/13/53)

Four 90° two-dimensional turning passages designed by the method of characteristics were tested at an inlet Mach number of 1.71. The measured losses varied from 5 to 15 percent of the inlet stagnation pressure. The smallest loss was obtained for a passage in which separation on the convex surface was minimized through the introduction of a favorable pressure gradient.

NACA RM L9J05a

INVESTIGATION OF AN IMPULSE AXIAL-FLOW COMPRESSOR. John R. Erwin and Wallace M. Schulze. February 8, 1950. 51p. diagrs., photos. (NACA RM L9J05a) (Declassified from Restricted, 4/13/53)

An investigation was made of the possibility of obtaining high pressure coefficients by applying the constant-pressure principle to axial-flow compressors. Use of blade sections developed by cascade tests permitted the design of a rotor for 75° turning and a total-pressure coefficient of 2.40. This rotor was tested at low speeds with and without stator blades. A rotor total-pressure coefficient of 2.30 with an efficiency of 98.3 percent and a stage pressure coefficient of 2.05 with an efficiency of 89.6 percent were measured at a design quantity-flow coefficient of 0.82.

NACA RM L9K14a

TANK TESTS AT SUBCAVITATION SPEEDS OF AN ASPECT-RATIO-10 HYDROFOIL WITH A SINGLE STRUT. Kenneth L. Wadlin, John A. Ramsen and John R. McGehee. July 20, 1950. 31p. diagrs., photos. (NACA RM L9K14a) (Declassified from Confidential, 2/12/53)

An investigation was made in Langley tank No. 2 to determine the lift and drag of a high-aspect-ratio rectangular hydrofoil supported by a single strut. The model was tested at various depths below the water surface at speeds up to 35 feet per second corresponding to a Reynolds number of 2.0×10^6. A maximum lift-drag ratio of 25.4 was obtained with the hydrofoil at a depth of 1/2 chord. This ratio decreased and the lift coefficient at which it occurred increased with depth. The effects of the water surface were negligible at a depth of 2 chords or greater. The data in the speed range covered showed good agreement with corresponding aerodynamic data from wind-tunnel tests.

NACA RM L50F21a

EXPERIMENTAL INVESTIGATION OF THE MIXING LOSS BEHIND THE TRAILING EDGE OF A CASCADE OF THREE 90° SUPERSONIC TURNING PASSAGES. Luke L. Liccini. August 15, 1950. 31p. diagrs., photos., tab. (NACA RM L50F21a) (Declassified from Confidential, 4/13/53)

A two-dimensional cascade of three 90° turning passages, designed by the method of characteristics, was tested at an inlet Mach number of 1.18. The total loss across the cascade was 9 percent. Of this total, approximately 5 percent is chargeable to the mixing process downstream of the trailing edges. Although a variation of the boundary-layer thickness occurred across the span and resulted in a nonuniform turning angle, the effective turning was of the order of 90°. The wake survey indicates that the velocity tends to become uniform very rapidly behind the trailing edge in the blade wake.

NACA RM L50F27a

INVESTIGATION OF AN IMPULSE AXIAL-FLOW COMPRESSOR ROTOR OVER A RANGE OF BLADE ANGLES. Wallace M. Schulze, John R. Erwin and Willard R. Westphal. August 29, 1950. 34p. diagrs., photos. (NACA RM L50F27a) (Declassified from Confidential, 4/13/53)

An investigation was made of an impulse axial-flow rotor with blades designed for 75° turning to study its performance characteristics over a wide range of blade-angle settings and quantity rates of flow. Special emphasis was given to the stall-point area. A total-pressure-rise coefficient of 3.00 at 93 percent efficiency, and at a different blade-angle setting a static-pressure-rise coefficient of 0.53 at 90 percent efficiency were realized. Information on the stall charateristics of highly cambered blading and the conditions under which a rotor induces a flow were also discovered.

NACA RM L50G05

INVESTIGATION OF A SHROUDED AND AN UNSHROUDED AXIAL-FLOW SUPERSONIC COMPRESSOR. Emanuel Boxer and John R. Erwin. September 15, 1950. 54p. diagrs., photos., tab. (NACA RM L50G05) (Declassified from Confidential, 4/13/53)

Details of the design and results of tests of an unshrouded NACA supersonic axial-flow compressor in Freon 12 are presented. Blade sections thicker than previously used permitted operation without an attached shroud. Tests were made at tip speeds ranging from 866 feet per second to 1680 feet per second when converted to sea-level air. At equivalent tip speed of 1610 feet per second with guide vanes, the rotor produced a pressure ratio of 2.03 with 83.5 percent at an air-flow rate of 28.0 pounds per second; without vanes, the values are 2.20, 84.5 percent, and 27.8, respectively. In addition, shrouded-rotor results are compared with those obtained in air at the NACA Lewis Flight Propulsion Laboratory.

NACA RM L52B06

APPLICATION OF SUPERSONIC VORTEX-FLOW THEORY TO THE DESIGN OF SUPERSONIC IMPULSE COMPRESSOR- OR TURBINE-BLADE SECTIONS. Emanuel Boxer, James R. Sterrett and John Wlodarski. April 24, 1952. 70p. diagrs., photos., 4 tabs. (NACA RM L52B06) (Declassified from Confidential, 4/13/53)

A method of designing related supersonic turbine or compressor blade sections is developed based upon a known solution of supersonic vortex flow. A major part of the turning is accomplished by concentric circular streamlines which are generated by uniquely shaped transition arcs near the leading edge of blade surfaces. An examination of the supersonic starting criteria was made as well as means of thickening the leading- and trailing-edge portions. Cascade test results of four blade passages are presented.

NACA RM L52J27a

A SIMPLIFIED MATHEMATICAL MODEL FOR CALCULATING AERODYNAMIC LOADING AND DOWNWASH FOR MIDWING WING-FUSELAGE COMBINATIONS WITH WINGS OF ARBITRARY PLAN FORM. Martin Zlotnick and Samuel W. Robinson, Jr. January 16, 1953. 36p. diagrs. (NACA RM L52J27a) (Declassified from Restricted, 4/10/53)

It is shown that a satisfactory mathematical model for a midwing wing-fuselage combination in subsonic flow can be developed from a simple vortex-image system. Using this scheme, a method for calculating the lift on the fuselage in the presence of the wing is presented and illustrated by a numerical example. In addition it is shown how the simplified mathematical model can be used for calculating the downwash behind the wing and for calculating the spanwise lift distribution on the wing in the presence of the fuselage.

NACA Rept. 1086

ANALYSIS OF THE EFFECTS OF WING INTERFERENCE ON THE TAIL CONTRIBUTIONS TO THE ROLLING DERIVATIVES. William H. Michael, Jr. 1952. ii, 12p. diagrs. (NACA Rept. 1086. Formerly TN 2332)

An analysis of the effects of wing interference on the tail contributions to the rolling stability derivatives of complete airplane configurations is made by calculating the angularity of the air stream at the vertical tail due to rolling and determining the resulting forces and moments. Some sidewash results are presented for a limited range of wing plan forms and vertical-tail sizes. Equations for using the sidewash results to determine the tail contributions to the rolling derivatives are given and some comparisons with experimental data are made.

NACA Rept. 1092

FLIGHT INVESTIGATION OF THE EFFECT OF CONTROL CENTERING SPRINGS ON THE APPARENT SPIRAL STABILITY OF A PERSONAL-OWNER AIRPLANE. John P. Campbell, Paul A. Hunter, Donald E. Hewes and James B. Whitten. 1952. ii, 17p. diagrs., photo., 2 tabs. (NACA Rept. 1092. Formerly TN 2413)

A flight investigation has been conducted on a typical high-wing personal-owner airplane to determine the effect of control centering springs on apparent spiral stability. The centering springs were used in both the aileron and rudder control systems to provide both a positive centering action and a means of trimming the airplane.

NACA Rept. 1100

ON REFLECTION OF SHOCK WAVES FROM BOUNDARY LAYERS. H. W. Liepmann, A. Roshko and S. Dhawan, California Institute of Technology. 1952. ii, 29p. diagrs., photos., tab. (NACA Rept. 1100. Formerly TN 2334)

Measurements are presented at Mach numbers from about 1.3 to 1.5 of reflection characteristics and the relative upstream influence of shock waves impinging on a flat surface with both laminar and turbulent boundary layers. The difference between impulse and step waves is discussed and their interaction with the boundary layer is compared. General considerations on the experimental production of shock waves from wedges and cones and examples of reflection of shock waves from supersonic shear layers are also presented.

NACA TN 2694

A METHOD FOR STABILIZING SHOCK WAVES IN CHANNEL FLOW BY MEANS OF A SURGE CHAMBER. Stanford E. Neice, Cornell University. June 1953. 46p. photos., diagrs. (NACA TN 2694)

In order to stabilize normal-shock waves in channel flow against the effect of disturbances originating downstream, a method based on mass removal from the channel by means of a surge chamber was developed and experimentally tested in an intermittent blowdown-type wind tunnel at Cornell University. A theoretical analysis was applied to a channel shape similar to that used in a typical supersonic wind tunnel and indicated that the mass-removal technique was effective in damping the motion of the normal shock caused by a strong pulse originating downstream. Experimental results were in direct agreement with the theoretical analysis. Further experiments indicated that the mass-removal technique was effective in damping the oscillatory motion of the normal shock caused by continuous small, random, downstream disturbances.

NACA TN 2933

BEHAVIOR OF MATERIALS UNDER CONDITIONS OF THERMAL STRESS. S. S. Manson. July 1953. 105p. diagrs., photos., 6 tabs. (NACA TN 2933)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE; THE REPORT TITLE AND AUTHOR.

A review is presented of available information on the behavior of brittle and ductile materials under conditions of thermal stress and thermal shock. For brittle materials, simple formulas relating physical properties to thermal-shock resistance are derived and used to determine the relative significance of two indices currently in use for rating materials. The importance of simulating operating conditions in thermal-shock testing is deduced from the formula and is experimentally illustrated by showing that BeO could be both inferior or superior to Al_2O_3 in thermal shock depending on the testing conditions. For ductile materials, thermal-shock resistance depends upon the complex interrelation among several metallurgical variables which seriously affect strength and ductility. These variables are briefly discussed and illustrated from literature sources. The importance of simulating operating conditions in tests for rating ductile materials is especially to be emphasized because of the importance of testing conditions in metallurgy. A number of practical methods that have been used to minimize the deleterious effects of thermal stress and thermal shock are outlined.

NACA TN 2954

THE STRUCTURE OF TURBULENCE IN FULLY DEVELOPED PIPE FLOW. John Laufer, National Bureau of Standards. June 1953. 53p. diagrs. (NACA TN 2954)

Measurements, principally with a hot-wire anemometer, were made in fully developed turbulent flow in a 10-inch pipe at speeds of 10 and 100 feet per second. It is shown that rates of turbulent-energy production, dissipation, and diffusion have sharp maximums near the edge of the laminar sublayer and that there exist a strong movement of kinetic energy away from this point and an equally strong movement of pressure energy toward it. It is suggested that the flow field may be divided into three regions: Wall proximity where turbulence production, transfer, and viscous action are of about equal importance; the central region of the pipe where energy diffusion predominates; and the intermediate region where the local rate of change of turbulent-energy production dominates the energy received by diffusive action.

NACA TN 2956

CREEP-BUCKLING ANALYSIS OF RECTANGULAR-SECTION COLUMNS. Charles Libove. June 1953. 24p. diagrs. (NACA TN 2956)

A previous analysis of the creep behavior of a slightly curved pin-ended H-section column under constant load is extended to the slightly curved solid rectangular-section column. The analysis leads to a differential equation for the plastic strains at the midheight cross section. The form of the equation indicates the significant parameters which may be useful in plotting test data on the creep life of columns. These are a lifetime parameter t'_{cr}, an initial-straightness parameter S or S', and the ratio of the average applied stress to the Euler stress $\bar{\sigma}/\sigma_E$. A numerical method of solving the differential equation, suitable for use with a high-speed digital computer, is described, and typical computed results are given. The existence of a finite lifetime, although not evident from the differential equation, is argued intuitively and confirmed by the numerical computations.

NACA TN 2957

SURVEYS OF THE FLOW FIELDS AT THE PROPELLER PLANES OF SIX 40° SWEPTBACK WING-FUSELAGE-NACELLE COMBINATIONS. Vernon L. Rogallo and John L. McCloud III. June 1953. 57p. diagrs., photos. (NACA TN 2957)

The flow fields at the propeller planes of six 40° sweptback, semispan wing-fuselage-nacelle combinations have been surveyed. The significance of the flow-field parameters in terms of propeller-oscillating aerodynamic loads is indicated. Comparisons of measured and predicted upflow angles are made for all six models.

NACA TN 2958

REACTION PROCESSES LEADING TO SPONTANEOUS IGNITION OF HYDROCARBONS. Charles E. Frank and Angus U. Blackham, University of Cincinnati. June 1953. 27p. diagrs., 6 tabs. (NACA TN 2958)

The vapor-phase oxidation of isooctane at 500° C under conditions leading to rapid quenching of the reaction yields hydrogen peroxide, diisobutylene, and isobutylene as the major reaction products. As the reaction time increases, the formation of acetone and formaldehyde becomes of primary importance. Under otherwise similar conditions, n-heptane is attacked at 350° C to yield a mixture of organic peroxides as the major initial product. The next phase of reaction develops with extreme rapidity, leading mainly to the formation of a mixture of aldehydes and ketones (principally formaldehyde). The marked differences between the oxidation behavior of these two hydrocarbons are interpreted on the basis of the temperature required for oxidative attack and of the thermal stability of the alkyl and peroxy radicals obtained. Preliminary results on the oxidation of isobutane and 2, 2, 5-trimethylhexane afford additional evidence for these generalizations.

NACA TN 2959

THEORETICAL INVESTIGATION OF THE SUPERSONIC LIFT AND DRAG OF THIN, SWEPTBACK WINGS WITH INCREASED SWEEP NEAR THE ROOT. Doris Cohen and Morris D. Friedman. June 1953. 51p. diagrs. (NACA TN 2959)

Formulas are derived by the use of linear theory for the lift and drag due to lift, at supersonic speeds, of thin flat wings having a discontinuity in the leading-edge sweep, with the inboard portion of the leading edge very highly swept, the outboard portion less so. Examples show the effect of the bend in the leading edge on the pressure distribution, the lift-curve slope, and drag. The results are also related to the effect of a wing-fuselage juncture on the lift on the wing.

NACA TN 2960

DRAG OF CIRCULAR CYLINDERS FOR A WIDE RANGE OF REYNOLDS NUMBERS AND MACH NUMBERS. Forrest E. Gowen and Edward W. Perkins. June 1953. 26p. diagrs., photos. (NACA TN 2960. Formerly RM A52C20)

Pressure distribution measurements on a two-dimensional circular cylinder have been made at high subsonic and supersonic speeds. Drag coefficients obtained from these measurements are presented with results from other sources. It was found that a maximum drag coefficient of about 2.1 occurs near sonic velocity. As the Mach number was increased to 2.9 the drag coefficient decreased to about 1.34. No effects of Reynolds number were found at supercritical Mach numbers. Effects of fineness ratio on drag of three-dimensional cylinders at supersonic speeds were investigated and found to be small.

NACA TN 2961

SUBSONIC FLOW OF AIR THROUGH A SINGLE-STAGE AND A SEVEN-STAGE COMPRESSOR. Chung-Hua Wu. June 1953. 32p. diagrs., 2 tabs. (NACA TN 2961)

A method recently developed for solving the steady flow of a nonviscous compressible fluid along a relative stream surface between two adjacent blades in a turbomachine is applied to investigate the low- and high-speed subsonic air flow through a single and through a seven-stage axial compressor. Appreciable radial flow results from the radially increasing values of the angular momentum of the air particles associated with the "symmetrical velocity diagram at all radii" used in the examples. The axial-velocity distribution obtained for the example checked well with a simple approximation solution obtained previously by assuming simple sinusoidal radial-flow paths.

NACA TN 2962

EFFECT OF ICE AND FROST FORMATIONS ON DRAG OF NACA 65_1-212 AIRFOIL FOR VARIOUS MODES OF THERMAL ICE PROTECTION. Vernon H. Gray and Uwe H. von Glahn. June 1953. 68p. diagrs., photos. (NACA TN 2962)

Studies were made to determine the effect of ice and frost formations on the drag of an 8-foot-chord NACA 65_1-212 airfoil. At high angles of attack (8°), glaze-ice formations on the upper surface near the leading edge of an airfoil caused large increases in drag and incipient stalling of the airfoil. Runback icing on the lower surface, except for heavy spanwise ice ridges, presented no serious drag problems. Rime-ice formations on the leading edge did not cause large drag increases. Cyclic de-icing of the leading edge successfully decreased the drag almost to the bare airfoil drag value. Frost formations on airfoil surfaces caused large drag increases and may result in stalling of the airfoil.

NACA TN 2963

EFFECT OF VARIATION IN RIVET STRENGTH ON THE AVERAGE STRESS AT MAXIMUM LOAD FOR ALUMINUM-ALLOY, FLAT, Z-STIFFENED COMPRESSION PANELS THAT FAIL BY LOCAL BUCKLING. Norris F. Dow, William A. Hickman and B. Walter Rosen. June 1953. 17p. diagrs., 2 tabs. (NACA TN 2963)

A study is made of the effect of variation in rivet strength on the average stress at maximum load for 75S-T6 aluminum-alloy, flat, Z-stiffened compression panels that fail by local buckling. A curve is presented for the determination of the relationship between strength, diameter, and pitch of the rivets and the strength of stiffened, flat compression panels of such proportions that failure is by local buckling.

NACA TN 2964

A REVISED FORMULA FOR THE CALCULATION OF GUST LOADS. Kermit G. Pratt. June 1953. 15p. diagrs. (NACA TN 2964)

A revised gust-load formula with a new gust factor is derived to replace the gust-load formula widely used in gust studies. The revised formula utilizes the same principles and retains the same simple form of the original formula. The gust factor is calculated on the basis of a one-minus-cosine gust shape and is presented as a function of mass ratio as compared to the ramp gust shape and wing loading, respectively, used for the alleviation factor.

NACA TN 2968

PROPELLER-NOISE CHARTS FOR TRANSPORT AIRPLANES. Harvey H. Hubbard. June 1953. 47p. diagrs., photos., tab. (NACA TN 2968)

Calculations of rotational-noise and vortex-noise levels at a distance of 300 feet for engine ratings of 1,000 to 10,000 horsepower have been made for a large number of propellers in static operation. Propellers with three, four, six, and eight blades and diameters of 8, 12, 16, and 20 feet are considered. The results are presented in chart and table form for rapid estimation of the noise levels and spectrums in the range of tip Mach numbers from 0.40 to 1.00. Applications of the data to tandem and dual-rotating configurations are given and the supersonic-type propeller is also briefly considered.

NACA TN 2969

THE CONDENSATION LINE OF AIR AND THE HEATS OF VAPORIZATION OF OXYGEN AND NITROGEN. George T. Furukawa and Robert E. McCoskey, National Bureau of Standards. June 1953. 30p. diagrs., 8 tabs. (NACA TN 2969)

The condensation pressure of air was determined over the range of temperature from 60° to 85° K. The experimental results were slightly higher than the calculated values based on the ideal solution law. Heat of vaporization of oxygen was determined at four temperatures ranging from about 68° to 91° K and of nitrogen similarly at four temperatures ranging from 62° to 78° K.

NACA TN 2970

PHYSICAL PROPERTIES OF CONCENTRATED NITRIC ACID. W. L. Sibbitt, C. R. St. Clair, T. R. Bump, P. F. Pagerey, J. P. Kern and D. W. Fyfe, Purdue University. June 1953. 19p. diagrs., 2 tabs. (NACA TN 2970)

From a review of the literature and additional experimental measurements, recommended values of the physical properties of white fuming nitric acid were determined for the temperature range of approximately -35° to 300° F. These properties included thermal conductivity, dynamic viscosity, specific heat, density, and vapor pressure. Values were determined within an accuracy of 5 percent for all physical properties except the vapor pressure.

NACA RM E53C27

COMPARISON OF SEVERAL METHODS OF CYCLIC DE-ICING OF A GAS-HEATED AIRFOIL. Vernon H. Gray and Dean T. Bowden. June 1953. 66p. diagrs., photos., 2 tabs. (NACA RM E53C27)

Several methods of cyclic de-icing of a gas-heated airfoil were investigated to determine ice-removal characteristics and heating requirements. The cyclic de-icing system with a spanwise ice-free parting strip in the stagnation region and a constant-temperature gas-supply duct gave the quickest and most reliable ice removal. Heating requirements for the several methods of cyclic de-icing are compared, and the savings over continuous ice prevention are shown. Data are presented to show the relation of surface temperature, rate of surface heating, and heating time to the removal of ice.

NACA RM E53D06

INVESTIGATION OF EFFECTS OF GRAIN SIZE UPON ENGINE LIFE OF CAST AMS 5385 GAS TURBINE BLADES. C. A. Hoffman and C. A. Gyorgak. July 1953. 21p. diagr., photos., 5 tabs. (NACA RM E53D06)

An investigation was conducted to (a) determine the effects of pouring temperature and grain size upon uniformity of lives and initial failure times of groups of experimentally cast AMS 5385 gas turbine blades aged 24 hours at 1350° F and (b) relate individual lives of these experimentally cast blades to grain size. Grain size varied from 4 to 11, 200 (A. S. T. M. 8) grains per cross section. Commercially produced AMS 5385 blades were used as a control group. The blades were operated in a small gas turbine at a temperature of 1450° F and a midspan stress of 19, 000 pounds per square inch. A correlation was found to exist between number of grains per blade cross section and blade life for the experimentally cast blades; longer life was associated with the coarser grain sizes. Initial failure time and uniformity of life was better for the experimentally cast blades poured at the higher nominal temperature than those poured at the lower nominal temperature. The experimentally cast coarse-grained blades had better uniformity, similar initial failure time, but lower mean life than a group of commercially cast coarse-grain blades.

NACA RM E53D23

PROCEDURE FOR MEASURING LIQUID-WATER CONTENT AND DROPLET SIZES IN SUPERCOOLED CLOUDS BY ROTATING MULTICYLINDER METHOD. William Lewis, Porter J. Perkins and Rinaldo J. Brun. Appendix C: ALTERNATE METHOD OF REDUCING ROTATING MULTICYLINDER DATA. Paul T. Hacker. June 1953. 48p. diagrs., photos., 4 tabs. (NACA RM E53D23)

The rotating multicylinder method for in-flight determination of liquid-water content, droplet size, and droplet-size distribution in icing clouds is described. The theory of operation, the apparatus required, the technique of obtaining data in flight, and detailed methods of calculating the results, including necessary charts and tables, are presented.

NACA RM L53E04a

PRELIMINARY INVESTIGATIONS OF STRENGTH CHARACTERISTICS OF STRUCTURAL ELEMENTS AT ELEVATED TEMPERATURES. Eldon E. Mathauser and Charles Libove. June 1953. 12p. diagrs. (NACA RM L53E04a)

Methods for predicting structural strength of columns, plates, and stiffened panels at uniform elevated temperature are surveyed. For columns and plates, the material stress-strain curve is needed in determining short-time strength where creep effects are negligible, and, for stiffened panels, an "effective" stress-strain curve is useful. A method for determining the long-time, or creep, strength of columns is given. Some data obtained from creep tests on stiffened panels are included.

Royal Aircraft Establishment (Gt. Brit.)
CABIN AIR CONDITIONING IN HIGH SPEED FLIGHT. F. V. Davies. January 1953. 31p. diagrs., 3 tabs. (RAE Tech. Note Aero 2196)

Some heat transfer problems of air conditioning at high speeds are discussed and tentative requirements given for $0.5 < M < 2.0$. A rational formulation of requirements cannot be obtained until there is a background of experimental data on heat transfer and temperature distributions within the cabin itself and for the thermal resistance of the cabin walls. Cooling requirements become more severe as speeds increase and there are indications that unless the heat flow through the walls can be considerably reduced by insulation a cooling system supplementary to the air conditioning plant may be necessary for exceptional flight conditions.

THE BURNING OF SINGLE DROPS OF FUEL. PART IV. THE FLOW OF HEAT AND CARBON RESIDUE FORMATION IN DROPS OF FUEL. G. A. E. Godsave. October 1952. 30p. diagrs., 3 tabs. (NGTE R. 125)

Investigations have been made of the flow of heat in single drops of evaporating and burning fuel. Curves are given showing the distribution of temperature with time within these single drops. Data for the density, heat capacity, and thermal conductivity of petroleum products are presented in such a manner that the generalized temperature distribution curves can be applied to drops of any petroleum product, given only the normally specified value of the specific gravity at 60° F/60°F. These investigations are of general interest in connection with the associated studies of the heat transfer to evaporating and burning single drops of fuel. They have also added significance in that calculations based on the results enable conclusions to be drawn concerning the detailed mechanism of carbon residue formation during the combustion of drops of heavy fuels.

BOUNDARY LAYER EFFECT ON THE SURFACE PRESSURE OF AN INFINITE CONE IN SUPERSONIC FLOW. T. C. Lin, S. A. Schaaf and F. S. Sherman. March 5, 1951. i, 10p. diagrs. (California U., Berkeley. HE-150-80)

The theory of Taylor and Maccoll gives the surface pressure on an infinite cone in supersonic flow as a function of the cone vertex angle and the free stream Mach number and static pressure for a gas of vanishing viscosity. When a slender conical probe is used together with an impact pressure probe to determine the static pressure and Mach number in a low density gas stream, it is desirable to have some theoretical estimate of the effect of viscous boundary layer on the probe readings. A simple approximation for a conical probe based on linearized supersonic flow and compressible boundary-layer theory is presented here.

NACA RM A6G22

A STUDY OF SEVERAL PARAMETERS CONTROLLING THE TRAJECTORIES OF A SUPERSONIC ANTIAIRCRAFT MISSILE POWERED WITH SOLID- OR LIQUID-FUEL ROCKETS. Ralph F. Huntsberger. April 24, 1947. 42p. diagrs. (NACA RM A6G22) (Declassified from Restricted, 6/5/53)

The trajectories for a supersonic antiaircraft missile were calculated by a step-by-step integration method for a number of different conditions. The effects of changing drag, initial thrust ratio, and weight ratio, which are the principal variables controlling the trajectory for a fixed launching angle, were investigated.

NACA RM A7A31

DEVELOPMENT OF NACA SUBMERGED INLETS AND A COMPARISON WITH WING LEADING-EDGE INLETS FOR A 1/4-SCALE MODEL OF A FIGHTER AIRPLANE. Emmet A. Mossman and Donald E. Gault. August 7, 1947. 41p. diagrs., photos. 11 tabs. (NACA RM A7A31) (Declassified from Restricted, 6/5/53)

Characteristics of NACA submerged duct entries and wing leading-edge inlets designed for a 1/4-scale flow model of a fighter-type airplane powered by a jet engine in the fuselage are presented. Duct total-head losses at the simulated entrance to the jet engine and pressure distributions over the duct entries are shown. A comparison of the dynamic pressure recovery and critical Mach number of the two intake systems is made. Included is a discussion of methods of ameliorating a duct-flow instability which may appear with a twin-entrance submerged duct system.

NACA RM A7D11

MEASUREMENTS OF THE DAMPING IN ROLL OF LARGE-SCALE SWEPT-FORWARD AND SWEPT-BACK WINGS. Lynn W. Hunton and Joseph K. Dew. July 30, 1947. 39p. diagrs., photos., 2 tabs. (NACA RM A7D11) (Declassified from Restricted 6/5/53)

Wind-tunnel tests of five large-scale tapered wings which had angles of sweep of 0°, $\pm 30^{\circ}$, and $\pm 45^{\circ}$ have been conducted to determine the effects of both scale and sweep on the damping-in-roll parameter C_{l_p}. Rolling moment and pressure distribution were measured for each plain wing while in steady roll for an angle-of-attack range of -1° to 29°. The effects of both Reynolds number and deflection of partial-span split flaps were determined from less comprehensive tests. Several methods of predicting both the damping-in-roll and autorotational characteristics of the swept wings have been analyzed, and predicted results have been compared with the experimental data.

NACA RM A7F06

AN INVESTIGATION AT LOW SPEED OF A LARGE-SCALE TRIANGULAR WING OF ASPECT RATIO TWO. I - CHARACTERISTICS OF A WING HAVING A DOUBLE-WEDGE AIRFOIL SECTION WITH MAXIMUM THICKNESS AT 20-PERCENT CHORD. Adrien E. Anderson. November 13, 1947. 59p. diagrs., photos., tab. (NACA RM A7F06) (Declassified from Restricted, 6/5/53)

An investigation has been made of the low-speed characteristics of a 25-foot span triangular wing having an aspect ratio of 2. The airfoil section of the wing was a symmetrical double wedge with 5-percent maximum thickness at 20-percent chord. Force and moment data were obtained at several angles of sideslip for various configurations of 18.5-percent area, constant-chord split flaps, 10-percent-chord nose flaps, and semispan split-flap-type ailerons. Lift and drag data were obtained from the plain wing through a limited angle-of-attack range for Reynolds number varying between 13 and 34 million, as based on the mean aerodynamic chord.

NACA RM A7F30

A SUGGESTED METHOD OF ANALYZING FOR TRANSONIC FLUTTER OF CONTROL SURFACES BASED ON AVAILABLE EXPERIMENTAL EVIDENCE. Albert L. Erickson and Jack D. Stephenson. December 16, 1947. 59p. diagrs., photos., 2 tabs. (NACA RM A7F30) (Declassified from Confidential, 6/5/53)

Results of a transonic flutter investigation using a three-dimensional wing with a 65_1-213, a = 0.5 airfoil section are analyzed. An empirical theory is developed and checked against the results of two additional tests of small-scale models.

NACA RM A7G18

WING-FLOW TESTS OF A TRIANGULAR WING OF ASPECT RATIO TWO. I. EFFECTIVENESS OF SEVERAL TYPES OF TRAILING-EDGE FLAPS ON FLAT-PLATE MODELS. George A. Rathert, Jr. and George E. Cooper. November 14, 1947. 61p. diagrs., photos. (NACA RM A7G18) (Declassified from Confidential, 6/5/53)

This report contains the results of an investigation conducted by the wing-flow method of the effectiveness of several different types of longitudinal control flap on a flat-plate triangular plan form of aspect ratio 2. The control effectiveness parameters $d\alpha/d\delta_f$ and $dC_m/d\delta_f$ were determined for $C_N=0$ from a Mach number of 0.50 to 1.10 at Reynolds numbers of 500,000 to 1,300,000. Neither the basic plan form nor any of the controls exhibited any critical stick-fixed characteristics in the transonic speed range.

NACA RM A7H19

CHARACTERISTICS OF A 15-PERCENT-CHORD AND A 35-PERCENT-CHORD PLAIN FLAP ON THE NACA 0006 AIRFOIL SECTION AT HIGH SUBSONIC SPEEDS. Richard J. Ilk. October 2, 1947. 33p. diagrs., tab. (NACA RM A7H19) (Declassified from Restricted, 5/6/53)

Wind-tunnel tests have been made to determine the aerodynamic characteristics of a 15-percent- and a 35-percent-chord plain trailing-edge flap on the NACA 0006 airfoil section. Simultaneous measurements of section lift, drag, and pitching moment were made over a range of Mach numbers from 0.3 to approximately 0.9 at angles of attack ranging from -8° to 12° for flap deflections of 0°, 5°, and 10°. Increments of section lift coefficient and changes in airfoil angle of attack necessary to maintain constant lift with unit changes in flap deflection are presented as a measure of the effectiveness at high subsonic speeds of a plain flap employed on a very thin profile.

NACA RM A7H28

AN INVESTIGATION AT LOW SPEED OF A LARGE-SCALE TRIANGULAR WING OF ASPECT RATIO TWO. II - THE EFFECT OF AIRFOIL SECTION MODIFICATIONS AND THE DETERMINATION OF THE WAKE DOWNWASH. Adrien E. Anderson. December 10, 1947. 78p. diagrs., photos., tab. (NACA RM A7H28) (Declassified from Restricted, 6/5/53)

This report contains force and moment data obtained throughout the angle-of-attack range for a triangular wing having a symmetrical double-wedge airfoil section and various degrees of rounding of the wing leading edge and maximum thickness. The dynamic pressure and downwash angle in the wake are also presented.

NACA RM A7I29

TESTS OF SUBMERGED DUCT INSTALLATION ON A MODIFIED FIGHTER AIRPLANE IN THE AMES 40- BY 80-FOOT WIND TUNNEL. Norman J. Martin. December 11, 1947. 25p. diagrs., photos., 2 tabs. (NACA RM A7I29) (Declassified from Confidential, 6/5/53)

An investigation of an NACA submerged intake installation on a modified fighter airplane was conducted to determine the full-scale aerodynamic characteristics of this installation. In addition, tests were conducted on the submerged inlet with revised entrance lips and deflectors to determine the configuration which would result in the best dynamic pressure recovery measured at the inlet for this installation without a major rework of the entrance.

NACA RM A7L11

LOW-SPEED INVESTIGATION OF A SMALL TRIANGULAR WING OF ASPECT RATIO 2.0. II - FLAPS. Leonard M. Rose. August 9, 1948. 17p. diagrs., photo. (NACA RM A7L11) (Declassified from Restricted, 6/11/53)

Split and plain trailing-edge flaps were tested on flat-plate models having an aspect ratio of 2.0 and 63.4° sweepback of the leading edge. A constant chord flap was found to be the most effective and a skewed wing tip flap the least effective. Some additional tests of short-span split flaps at several chordwise locations indicate the possibility of obtaining balancing moments without loss in lift or changes in lift without change in attitude or balance.

NACA RM A8C03

LOW-SPEED INVESTIGATION OF A SMALL TRIANGULAR WING OF ASPECT RATIO 2.0. III - STATIC STABILITY WITH TWIN VERTICAL FINS. Leonard M. Rose. August 24, 1948. 11p. diagrs. (NACA RM A8C03) (Declassified from Restricted, 6/11/53)

Twin vertical fins were tested on a triangular wing. It was found that these fins maintained substantially constant effectiveness throughout the angle-of-attack range. The addition of the twin fins resulted in a loss in maximum lift and a reduction in static longitudinal stability at lift coefficients above 0.4.

NACA RM A9I26

ESTIMATION OF THE FORCES AND MOMENTS ACTING ON INCLINED BODIES OF REVOLUTION OF HIGH FINENESS RATIO. H. Julian Allen. November 14, 1949. 27p. diagrs. (NACA RM A9I26) (Declassified from Restricted, 6/11/53)

An approximate theory including an allowance of the effects of viscosity on inclined bodies of revolution is developed. Calculations based on this theory are compared with experiment. Discussion of the probable effects of Reynolds and Mach number is included.

NACA RM E7B11a

COOLING OF GAS TURBINES. I - EFFECTS OF ADDITION OF FINS TO BLADE TIPS AND ROTOR, ADMISSION OF COOLING AIR THROUGH PART OF NOZZLES, AND CHANGE IN THERMAL CONDUCTIVITY OF TURBINE COMPONENTS. W. Byron Brown. February 11, 1947. 26p. diagrs. (NACA RM E7B11a) (Declassified from Restricted, 6/5/53)

An analysis was developed for calculating the radial temperature distribution in a gas turbine with only the temperatures of the gas and the cooling air and the surface heat-transfer coefficients known. This analysis was applied to determine the temperatures of a complete wheel of a conventional single-stage impulse exhaust-gas turbine. The temperatures were first calculated for the case of the turbine operating at design conditions of speed, gas flow, etc., and with only the customary cooling arising from exposure of the outer blade flange and one face of the rotor to the air. Calculations were next made for the case of fins applied to the outer blade flange and the rotor. Finally the effects of using part of the nozzles for supplying cooling air and the effects of varying the metal thermal conductivity from 12 to 260 Btu per hour per foot per °F on the wheel temperatures were determined. The gas temperatures at the nozzle box used in the calculations ranged from 1600° F to 2000° F.

NACA RM E7B11b

COOLING OF GAS TURBINES. II - EFFECTIVENESS OF RIM COOLING OF BLADES. Lincoln Wolfenstein, Gene L. Meyer and John S. McCarthy. March 18, 1947. 31p. diagrs. (NACA RM E7B11b) (Declassified from Restricted, 6/5/53)

An analysis is presented of rim cooling of gas-turbine blades; that is, reducing the temperature at the base of the blade (wheel rim), which cools the blade by conduction alone. Formulas for temperature and stress distributions along the blade are derived and, by the use of experimental stress-rupture data for a typical blade alloy, a relation is established between blade life (time for rupture), operating speed, and amount of rim cooling for several gas temperatures. The effect of a blade parameter combining the effects of blade dimensions, blade thermal conductivity, and heat-transfer coefficient is determined. The effect of radiation on the results is approximated.

NACA RM E7G23

INVESTIGATION OF THRUST AUGMENTATION OF A 1600-POUND THRUST CENTRIFUGAL-FLOW-TYPE TURBOJET ENGINE BY INJECTION OF REFRIGERANTS AT COMPRESSOR INLETS. William L. Jones and Harry W. Dowman. August 25, 1947. 44p. diagrs., photo., tab. (NACA RM E7G23) (Declassified from Restricted, 6/5/53)

The performance of a centrifugal-flow-type turbojet engine (having a normal military rating of 1600-lb thrust at a rotor speed of 16,500 rpm), has been investigated at zero flight speed with injection of refrigerants at the compressor inlets. The largest part of these investigations was devoted to the injection of water and water-alcohol mixtures; brief investigations were also conducted with the injection of kerosene and carbon dioxide.

NACA RM E7G29

FLIGHT INVESTIGATION OF THRUST AUGMENTATION OF A TURBOJET ENGINE BY WATER-ALCOHOL INJECTION. Carl Ellisman. September 29, 1947. 20p. diagrs., photos. (NACA RM E7G29) (Declassified from Restricted, 6/5/53)

Thrust augmentation by injection of water-alcohol mixtures into compressor inlets of turbojet engines was investigated in flight at sea level, 5,000 and 10,000 feet to determine water-alcohol mixture and injection rate for optimum thrust augmentation. The mixture of 20 percent alcohol by weight and an injection rate of 1.45 pounds per second produced maximum thrust augmentation at 10,000 feet. This injection rate was equivalent to a water-alcohol-to-air ratio of approximately 0.05 and gave a 21 percent increase in net thrust. Below 10,000 feet the optimum water-alcohol-to-air ratio was within the range of 0.03 to 0.05.

NACA RM E7G30

COOLING OF GAS TURBINES. VII - EFFECTIVENESS OF AIR COOLING OF HOLLOW TURBINE BLADES WITH INSERTS. Joseph R. Bressman and John N. B. Livingood. October 20, 1947. 51p. diagrs., 2 tabs. (NACA RM E7G30. Now Rept. 994) (Declassified from Restricted, 6/5/53)

Contains results of analytical investigation to determine reduction in cooling-air requirements and increase in effective gas temperature for same quantity of cooling air resulting from use of insert in cooling-air passage of hollow air-cooled turbine blade. Effects of neglecting radiation and radial heat conduction on dilution and effects of variations in blade-root, average insert, and blade-root cooling-air temperatures on blade temperature are included. Insert that reduced cooling-air mass flow to minimum hot-gas flow ratio one-half reduced air mass flow two-thirds and three-fifths for adequate cooling.

NACA RM E7I22a

COOLING OF GAS TURBINES. VIII - THEORETICAL TEMPERATURE DISTRIBUTIONS THROUGH GAS TURBINE WITH SPECIAL BLADES AND COOLING FINS ON THE RIM. W. Byron Brown and John N. B. Livingood. February 17, 1948. 21p. diagrs. (NACA RM E7I22a) (Declassified from Restricted, 6/11/53)

Presents effects on blade life and effective gas temperature of analytical investigation of addition of cooling fins on the rim. Also contains two-dimensional temperature distributions through the turbine and three-dimensional temperature distributions through a section of the rim near a blade root, both obtained by relaxation. Addition of cooling fins on the rim doubled blade life and permitted a 30° F increase in effective gas temperature. Proof was obtained that a one-dimensional distribution is sufficiently accurate for most applications.

NACA RM E7I25

A COMPARISON OF THE SIMULATED-ALTITUDE PERFORMANCE OF TWO TURBOJET COMBUSTOR TYPES. Ray E. Bolz, Thomas T. Schroeter and Eugene V. Zettle. October 7, 1948. 34p. diagrs. (NACA RM E7I25) (Declassified from Restricted, 6/11/53)

Performance of German Jumo 004 can-type combustor and of two contemporary turbojet combustors of U. S. design, annular and can type, were compared to determine whether advance stage in combustor design had been reached with Jumo 004 and to determine whether there are basic, inherent differences in performance achieved with either can or annular type. Combustors are compared with respect to altitude operational limits, combustion efficiency, and total-pressure loss across combustors. Neither of two U. S. combustor types showed basic inherent advantages or disadvantages when compared. The German combustor under given conditions of investigation resulted in performance that is generally poorer than that of U. S. combustors.

NACA RM L6H28a

INVESTIGATION OF THE CHARACTERISTICS OF A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Richard T. Whitcomb. August 28, 1946. 77p. diagrs., photos., 3 tabs. (NACA RM L6H28a) (Declassified from Restricted, 6/5/53)

An investigation of the characteristics of a wing with an aspect ratio of 9.0 and an NACA 65-210 airfoil section has been made at Mach numbers up to 0.925. The wing tested has a taper ratio of 2.5:1.0, no twist, dihedral, or sweepback, and 20-percent-chord 37.5-percent-semispan plain ailerons. Results presented include the normal-force, span-loading, pitching-moment, drag, and wake-width data for the wing alone with undeflected straight-sided ailerons.

NACA RM L6H28b

PRELIMINARY INVESTIGATION OF DOWNWASH FLUCTUATIONS OF A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Antonio Ferri. August 28, 1946. 25p. diagrs. (NACA RM L6H28b) (Declassified from Restricted, 6/5/53)

A series of tests has been made in the wake of a high-speed wing of high aspect ratio at Mach numbers up to approximately 0.90 to determine the fluctuations of the downwash in the zone of possible tail locations. Serious fluctuations occurred in the wake of the wing. The fluctuations extended beyond the wake boundaries but with decreasing amplitude. For a high angle of attack of the wing and high Mach numbers the fluctuations were very large and extended as high as approximately 0.90 chord above the chord line of the wing. For medium angles of attack important fluctuations occurred up to about 0.70 chord above the chord line of the wing.

NACA RM L6H28c

INVESTIGATION OF DIVE BRAKES AND A DIVE-RECOVERY FLAP ON A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Axel T. Mattson. August 28, 1946. 118p. diagrs., photos., tab. (NACA RM L6H28c) (Declassified from Restricted, 6/5/53)

The results of tests made to determine the aerodynamic characteristics of a solid brake, a slotted brake, and a dive-recovery flap mounted on a high-aspect-ratio wing at high Mach numbers are presented. The data were obtained in the Langley 8-foot high-speed tunnel for corrected Mach numbers up to 0.940. The results have been analyzed with regard to the suitability of dive-control devices for a proposed high-speed airplane in limiting the airplane terminal Mach number by the use of dive brakes and in achieving favorable dive-recovery characteristics by the use of a dive-recovery flap.

NACA RM L6H28d

AN INVESTIGATION OF A HIGH-ASPECT-RATIO WING HAVING 0.20-CHORD PLAIN AILERONS IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Arvo A. Luoma. August 28, 1946. 124p. diagrs., photos., 2 tabs. (NACA RM L6H28d) (Declassified from Restricted, 6/5/53)

A three-dimensional lateral-control investigation was made at high speeds of a wing of high aspect ratio having 0.20-chord straight-sided profile plain ailerons with a span 37.5-percent of the wing semispan. Spanwise loadings and moments and rolling-moment coefficients were obtained from pressure-distribution measurements, and hinge-moment data were obtained by an electrical strain gage for Mach numbers up to 0.925 at aileron deflections from -10° to 10° and at various angles of attack.

NACA RM L6J31

PRELIMINARY INVESTIGATION OF A NEW TYPE OF SUPERSONIC INLET. Antonio Ferri and Louis M. Nucci. November 27, 1946. 35p. diagrs., photos. (NACA RM L6J31. Now TN 2286) (Declassified from Restricted, 6/5/53)

A supersonic inlet with supersonic deceleration of the flow entirely outside of the inlet is considered. A particular arrangement with fixed geometry having a central body with a circular annular intake is analyzed, and it is shown theoretically that this arrangement gives high pressure recovery for a large range of Mach number and mass flow and therefore is practical for use on supersonic airplanes and missiles. For some Mach numbers the drag coefficient for this type of inlet is larger than the drag coefficient for the type of inlet with supersonic compression entirely inside, but the pressure recovery is larger for all flight conditions. The differences in drag can be eliminated for the design Mach number.

NACA RM L6L10a

AN INVESTIGATION OF THE HINGE-MOMENT FLUCTUATIONS OF 0.20-CHORD PLAIN AILERONS ON A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Arvo A. Luoma and Luke L. Liccini. January 10, 1947. 9p. diagrs. (NACA RM L6L10a) (Declassified from Restricted, 6/5/53)

Concurrently with a three-dimensional lateral-control investigation made in the Langley 8-foot high-speed tunnel of a wing of high aspect ratio having 0.20-chord, straight-sided-profile plain ailerons, a few photographic records of aileron vibrations were obtained by means of an oscillograph connected to the electrical strain gage used to measure aileron hinge moments. At supercritical Mach numbers, frequencies of the order of magnitude of 50 to 100 cycles per second were observed for the hinge-moment fluctuations of the aileron of the model. For a 104.5-foot-span airplane, full-scale hinge-moment-fluctuation frequencies (based on the model frequencies) are indicated to be of the same order of magnitude as the wing natural frequencies for an airplane of this size.

NACA RM L6L10b

INVESTIGATION AT HIGH SPEEDS OF A HORIZONTAL-TAIL MODEL IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Ralph P. Bielat. January 31, 1947. 102p. diagrs., 3 tabs. (NACA RM L6L10b)(Declassified from Restricted, 6/5/53)

Pressure-distribution measurements and elevator hinge-moment measurements were made to determine the aerodynamic characteristics of a horizontal-tail model having an NACA 65-108 airfoil section equipped with a 30-percent-chord sealed unbalanced elevator and a 10-percent-chord plain trim tab. The tests were made for various angles of attack and control-surface deflections at Mach numbers ranging from 0.40 to 0.90. Data are presented for tests made with the surfaces of the model smooth and also with boundary-layer transition fixed at the 0.10-chord station by a row of carborundum grains on each surface.

NACA RM L6L16

EFFECTS OF COMPRESSIBILITY ON THE CHARACTERISTICS OF FIVE AIRFOILS. Bernard N. Daley. April 25, 1947. 73p. diagrs., photos., tab. (NACA RM L6L16) (Declassified from Restricted, 6/5/53)

Pressure-distribution tests were made for determination of the effects of compressibility on the characteristics of the following 5-inch-chord airfoils: the NACA 66, 2-215, the NACA 66, 2-015, and the NACA 65(216)-418 sections representing the low-drag sections; the NACA 16-212 section, typical of the type designed for high critical speeds; and the NACA 23015 section, one of the older conventional airfoils. Schlieren photographs of the air flow and limited data concerning the wake characteristics were also obtained for the conventional airfoil. Data are presented for an approximate Mach number range from 0.34 to 0.75; the corresponding Reynolds number range is from 700,000 to 1,800,000.

NACA RM L7B27

INITIAL TEST IN THE TRANSONIC RANGE OF FOUR FLUTTER AIRFOILS ATTACHED TO A FREELY FALLING BODY. J. G. Barmby and S. A. Clevenson. May 5, 1947. 16p. diagrs., photo., 2 tabs. (NACA RM L7B27) (Declassified from Restricted, 6/5/53)

Results of the first test in the transonic range of four flutter airfoils attached to a freely falling body are reported. Failures of the airfoils were telemetered and recorded. These airfoils were designed in an attempt to spread the range of flutter speeds. Telemeter records show that three of the airfoils failed at Mach numbers between 0.87 and 0.90 at an altitude of 14,000 feet, and the fourth airfoil apparently failed at a Mach number of 1.025 at 1900 feet above sea level.

NACA RM L7J08

INITIAL FLIGHT TEST OF THE NACA FR-1-A, A LOW-ACCELERATION ROCKET-PROPELLED VEHICLE FOR TRANSONIC FLUTTER RESEARCH. Ellwyn E. Angle. 25p. diagrs., photos. (NACA RM L7J08) (Declassified from Restricted, 6/11/53)

The first of a series of flutter rockets, designated the NACA FR-1-A, was successfully launched and flown at the Pilotless Aircraft Research Station, Wallops Island, Va. Two identical swept wings were tested; the left wing failed at 967 feet per second (659 miles per hour, Mach number M = 0.89), and the right wing remained on the model throughout the entire flight (maximum Mach number of 1.0). The experimental value of failure speed obtained at a Mach number of 0.89 was 76.2 percent greater than the flutter speed obtained using the two-dimensional, incompressible, unswept-wing flutter theory.

NACA RM L7K17

FLUTTER INVESTIGATION IN THE TRANSONIC RANGE OF SIX AIRFOILS ATTACHED TO THREE FREELY FALLING BODIES. S. A. Clevenson and William T. Lauten, Jr. May 6, 1948. 32p. diagrs., photos., 2 tabs. (NACA RM L7K17) (Declassified from Restricted, 6/11/53)

Results of six flutter airfoils attached to three freely falling bodies are reported. Four similar airfoils, two unswept and two with 45° sweepback, fluttered at transonic Mach numbers. Flutter frequencies and phasing were recorded. One unswept airfoil reached the top Mach number of the bomb, M = 1.145, without flutter or failure. The results compare favorably with previous bomb and rocket tests.

NACA RM L8C24

FLIGHT TEST OF NACA FR-1-B, A LOW-ACCELERATION ROCKET-PROPELLED VEHICLE FOR TRANSONIC FLUTTER RESEARCH. Ellwyn E. Angle, Sherman A. Clevenson and Reginald R. Lundstrom. July 20, 1948. 22p. diagrs., photos., 3 tabs. (NACA RM L8C24) (Declassified from Restricted, 6/11/53)

A technique has been developed using a low acceleration rocket with strain-gage-type telemeter for determining the quantitative flutter characteristics of wings in a free air stream. Two 45° swept wings similar to those tested on the NACA FR-1-A rocket fluttered in a symmetrical mode at a frequency of 37 cycles per second at a Mach number of 0.65.

NACA RM L9L09

THE EFFECT OF CHANGES IN THE LEADING-EDGE RADIUS ON THE AERODYNAMIC CHARACTERISTICS OF A SYMMETRICAL, 9-PERCENT-THICK AIRFOIL AT HIGH-SUBSONIC MACH NUMBERS. Milton D. Humphreys and Raymond A. Robinson. August 7, 1950. 48p. diagrs., photos., tab. (NACA RM L9L09) (Declassified from Confidential, 5/25/53)

Wind-tunnel tests of the NACA 0009-64, 0009-54, and 0009-44 airfoils indicated that their leading-edge radii did not greatly influence their high-speed aerodynamic characteristics for Mach numbers up to 0.825. At a Mach number of 0.85 the drag of the NACA 0009-54 airfoil, having a leading-edge radius of 0.620 percent chord, appeared to be 12 to 25 percent lower than that of the other airfoils for normal-force coefficients in the range 0 to 0.3.

NACA RM L53B18

A METHOD FOR CALCULATING THE AERODYNAMIC LOADING ON WING-TIP-TANK COMBINATIONS IN SUBSONIC FLOW. Samuel W. Robinson, Jr. and Martin Zlotnick. April 7, 1953. 43p. diagrs. (NACA RM L53B18) (Declassified from Restricted, 4/9/53)

An analytical method for calculating the aerodynamic loading on wing-tip-tank combinations in subsonic flow is developed using a simple horseshoe vortex-image system for the case of the tank axis in the plane of the wing. An illustrative example is given in the appendix, in which wing and tip-tank loadings are calculated for three configurations. The calculated results are shown to be in good agreement with experimental data.

CURRENT NACA REPORTS

NACA Rept. 1095

TRANSONIC FLOW PAST A WEDGE PROFILE WITH DETACHED BOW WAVE. Walter G. Vincenti and Cleo B. Wagoner. 1952. ii, 30p. diagrs., tab. (NACA Rept. 1095. Formerly TN 2339; TN 2588)

A theoretical study has been made of the aerodynamic characteristics at zero angle of attack of a thin, doubly symmetrical double-wedge profile in the range of supersonic flight speed in which the bow wave is detached. The analysis utilizes the equations of the transonic small-disturbance theory and involves no assumptions beyond those implicit in this theory. The mixed flow about the front half of the profile is calculated by relaxation solution of a boundary-value problem for the transonic small-distrubance equation in the hodograph plane (that is, the Tricomi equation). The methods follow established lines except for the somewhat novel treatment of the boundary conditions along the shock polar and sonic line. The purely supersonic flow about the rear of the profile is found by means of the method of characteristics specialized to the transonic small-disturbance theory. Complete calculations were made for four values of the transonic similarity parameter. These were found sufficient to bridge the gap between the previous results of Guderley and Yoshihara at a Mach number of 1 and the results which are readily obtained when the bow wave is attached and the flow is completely supersonic.

NACA TN 2966

PROPELLER-PERFORMANCE CHARTS FOR TRANSPORT AIRPLANES. Jean Gilman, Jr. July 1953. 70p. diagrs. (NACA TN 2966)

The preliminary selection of a propeller on the basis of cruising and take-off performance for application to transport airplanes at flight Mach numbers up to 0.8 can be accomplished by the use of the charts and methods presented. The charts are of sufficient scope to permit a fairly rapid evaluation of the propeller performance for engine power ratings of 1,000 to 10,000 horsepower. The method is presented primarily in the interest of propeller-noise abatement.

NACA TN 2971

IMPINGEMENT OF WATER DROPLETS ON WEDGES AND DIAMOND AIRFOILS AT SUPERSONIC SPEEDS. John S. Serafini. July 1953. 62p. diagrs. (NACA TN 2971)

An analytical solution has been obtained for the equations of motion of water droplets impinging on a wedge in a two-dimensional supersonic flow field with a shock wave attached to the wedge. The closed-form solution yields analytical expressions for the equation of the droplet trajectory, the local rate of impingement and the impingement velocity at any point on the wedge surface, and the total rate of impingement. The analytical expressions are utilized to determine the impingement on the forward surfaces of diamond airfoils in supersonic flow fields with attached shock waves. The results presented include the following conditions: droplet diameters from 2 to 100 microns, pressure altitudes from sea level to 30,000 feet, free-stream static temperatures from 420° to 460° R, free-stream Mach numbers from 1.1 to 2.0, semi-apex angles for the wedge from 1.14° to 7.97°, thickness-to-chord ratios for the diamond airfoil from 0.02 to 0.14, chord lengths from 1 to 20 feet, and angles of attack from zero to the inverse tangent of the airfoil thickness-to-chord ratio.

NACA TN 2972

THEORETICAL PRESSURE DISTRIBUTIONS AND WAVE DRAGS FOR CONICAL BOATTAILS. John R. Jack. July 1953. 14p. diagrs. (NACA TN 2972)

Afterbody pressure distributions and wave drags were calculated using a second-order theory for a variety of conical boattails at zero angle of attack. Results are presented for Mach numbers from 1.5 to 4.5, area ratios from 0.200 to 0.800, and boattail angles from 3° to 11°. The results indicate that for a given boattail angle, the wave drag decreases with increasing Mach number and area ratio. The wave drag, for a constant area ratio, increases with increasing boattail angle. For a specific Mach number, area ratio, and fineness ratio, a comparison of the wave-drag coefficients for conical, tangent-parabolic, and secant-parabolic boattails showed the conical boattail to have the smallest wave drag.

NACA TN 2973

EFFECT OF PRESTRAINING ON RECRYSTALLIZATION TEMPERATURE AND MECHANICAL PROPERTIES OF COMMERCIAL, SINTERED, WROUGHT MOLYBDENUM. Kenneth C. Dike and Roger A. Long. July 1953. 25p. diagrs., photos., 3 tabs. (NACA TN 2973)

Given three presumably identical lots of commercial, sintered, wrought molybdenum, the 1-hour recrystallization temperature of one lot remained above

2900° F by limiting the amount of effective prestraining to 35 percent or less. Different recrystallization temperatures were obtained in various atmospheres, the highest in argon and the lowest in hydrogen. Metal thus fabricated and then stress-relieved possessed an ultimate tensile strength at room temperature within 10 percent of metal swaged 99 percent and also possessed equivalent ductility. At 1800° F, equivalent strength and ductility was obtained irrespective of the amount of swaging over the range of 10 to 99 percent. The amount of swaging greatly influenced the recrystallized grain size but the difference in grain size is not the major controlling factor which determines whether recrystallized molybdenum is ductile or brittle at room temperature.

NACA TN 2974

EXPERIMENTS ON MIXED-FREE- AND -FORCED-CONVECTIVE HEAT TRANSFER CONNECTED WITH TURBULENT FLOW THROUGH A SHORT TUBE. E. R. G. Eckert, Anthony J. Diaguila and Arthur N. Curren. July 1953. 59p. diagrs., photo. (NACA TN 2974)

Convective heat-transfer experiments were conducted for turbulent, mixed-free- and -forced-convection flow through a vertical heated tube with a length-to-diameter ratio of 5. Studies were made with forced air flowing parallel or opposite to the free convection flow. The Grashof numbers ranged from 10^9 to 10^{13} and the Reynolds numbers, from 36×10^3 to 377×10^3. These experiments together with results obtained by other investigators revealed that the total flow regime characterized by the Reynolds and Grashof numbers can be divided into a forced-flow regime, a free-flow regime, and a mixed-free- and -forced-convection regime. The limits for the different regimes were established.

NACA TN 2975

STRUCTURAL EFFICIENCIES OF VARIOUS ALUMINUM, TITANIUM, AND STEEL ALLOYS AT ELEVATED TEMPERATURES. George J. Heimerl and Philip J. Hughes. July 1953. 16p. diagrs., tab. (NACA TN 2975)

Efficient temperature ranges are indicated for two high-strength aluminum alloys, two titanium alloys, and three steels for some short-time compression-loading applications at elevated temperatures. Only the effects of constant temperatures and short exposure to temperature are considered, and creep is assumed not to be a factor. The structural efficiency analysis is based upon preliminary results of short-time elevated-temperature compressive stress-strain tests of the materials. The analysis covers strength under uniaxial compression, elastic stiffness, column buckling, and the buckling of long plates in compression or in shear.

NACA TN 2977

TECHNIQUES FOR CALCULATING PARAMETERS OF NONLINEAR DYNAMIC SYSTEMS FROM RESPONSE DATA. Benjamin R. Briggs and Arthur L. Jones. July 1953. ii, 67p. diagrs., 4 tabs. (NACA TN 2977)

A study has been made of the problem of determining parameters of dynamic systems, such as aircraft or servomechanisms, whose measured responses are nonlinear. The parameters studied were functions of displacement or velocity. The problem of determining such parameters involves both the recognition of the degree of nonlinearity of the data and the development of techniques of evaluation of the parameters.

NACA TN 2981

THE HIGH-SPEED PLANING CHARACTERISTICS OF A RECTANGULAR FLAT PLATE OVER A WIDE RANGE OF TRIM AND WETTED LENGTH. Irving Weinstein and Walter J. Kapryan. July 1953. 29p. diagrs., photo., 2 tabs. (NACA TN 2981)

The principal high-speed planing characteristics for a prismatic surface having an angle of dead rise of 0° (flat bottom) have been determined over a wide range of planing variables. Wetted length, resistance, center-of-pressure location, and draft were determined at speed coefficients ranging up to 25.0, beam loadings up to 87.3, and trims up to 30°. Mean wetted lengths up to 7.0 beams were obtained wherever possible.

NACA RM E53E04

MEASUREMENTS OF HEAT-TRANSFER AND FRICTION COEFFICIENTS FOR AIR FLOWING IN A TUBE OF LENGTH-DIAMETER RATIO OF 15 AT HIGH SURFACE TEMPERATURES. Walter F. Weiland and Warren H. Lowdermilk. July 1953. 19p. diagrs. (NACA RM E53E04)

Measurements of average heat-transfer and friction factors were obtained for air flowing through a smooth, electrically heated tube with a bellmouth entrance and a length-to-diameter ratio of 15 for a range of average surface temperature from 875° to 1735° R and corresponding surface-to-bulk temperature ratio from 1.6 to 2.8, Reynolds number from 2200 to 300,000, and heat fluxes up to 230,000 Btu/hr/ft^2 of heat-transfer area. The data of this investigation correlated with data obtained in previous investigations with longer tubes on the basis that the heat-transfer coefficient varies as the -0.1 power of the length-to-diameter ratio. No effect of the length-to-diameter ratio was observed on the average friction factor.

NACA RM E53E07

INVESTIGATION OF AERODYNAMIC AND ICING CHARACTERISTICS OF A FLUSH ALTERNATE-INLET INDUCTION-SYSTEM AIR SCOOP. James P. Lewis. July 1953. 42p. diagrs., photos. (NACA RM E53E07)

An investigation of the aerodynamic and icing characteristics of a full-scale induction-system air-scoop assembly incorporating a flush-type alternate inlet was conducted in the NACA Lewis icing research tunnel. The investigation was made over a range of mass-air-flow ratios, angles of attack, airspeeds, air temperatures, liquid-water content, and droplet sizes. The ram inlet gave good pressure recovery

in both clear air and icing, but rapid blocking of the carburetor screen occurred in icing. The alternate inlet had poor pressure recovery in both clear air and icing, but no serious screen icing was obtained. The investigation included the use of preheat air alone and in combination with ram- and alternate-inlet air.

NACA RM L52L29b

AN EXPERIMENTAL STUDY OF THE RELATION BETWEEN AIRPLANE AND WIND-VANE MEASUREMENTS OF ATMOSPHERIC TURBULENCE. H. B. Tolefson, K. G. Pratt and J. K. Thompson. July 1953. 20p. diagrs., photos., 3 tabs. (NACA RM L52L29b)

Analysis of simultaneous measurements of atmospheric turbulence by wind vanes mounted on a tower and by an airplane flying in the immediate vicinity of the tower indicates good correlation between the gust data for both sets of measurements. This correlation indicates that surface and airplane measurements of turbulence might be used interchangeably for engineering and meteorological purposes.

NACA RM L53E05a

SOME MEASUREMENTS OF LANDING CONTACT CONDITIONS OF TRANSPORT AIRPLANES IN ROUTINE OPERATIONS. Norman S. Silsby, Emanuel Rind and Garland J. Morris. July 1953. 8p. diagrs., photos. (NACA RM L53E05a)

Measurements have been obtained by means of a specially built motion-picture camera of 126 landings of current transport airplanes during routine operations at the Washington National Airport in clear-air daytime conditions. From these measurements, sinking speeds, roll attitude angles, and rolling velocities have been evaluated and a brief statistical analysis of the results has been made.

NACA TM 1357

AIR ADMIXTURE TO EXHAUST JETS. (Luftzumischung zu Abgasstrahlen). E. Sänger. July 1953. 35p. diagrs. (NACA TM 1357. Trans. from Ingenieur-Archiv, v. 18, no. 5, 1950, p. 310-323).

The problem of thrust increase by air admixture to exhaust jets of rockets, turbojet, ram- and pulse-jet engines is investigated theoretically. The optimum ratio of mixing chamber pressure to ambient pressure and speed range for thrust increase due to air admixture is determined for each type of jet engine.

NACA TM 1359

AIR-WATER ANALOGY AND THE STUDY OF HYDRAULIC MODELS. (La Similitudine Aria-Acqua e lo Studio dei Modelli Idraulici). Giulio Supino. July 1953. 22p. diagrs. (NACA TM 1359. Trans. from Energia Elettrica, v. 28, no. 11, Nov. 1951).

The author first sets forth some observations about the theory of models. Then he establishes certain general criteria for the construction of dynamically similar models in water and in air, through reference to the perfect fluid equations and to the ones pertaining to viscous flow. It is, in addition, pointed out that there are more cases in which the analogy is possible than is commonly supposed.

Royal Aircraft Establishment (Gt. Brit.) SOME ELECTRONIC MULTIPLIERS BASED ON DIODE FUNCTION SHAPERS. O. H. Lange and G. J. Herring. April 1953. 35p. diagrs., photos. (RAE Tech. Note GW 245)

Various types of analogue multipliers using electronic diodes are described in this report. They are either of the indirect type based on the relation $xy = \sin\alpha \sin\beta = \frac{\cos(\alpha - \beta) - \cos(\alpha + \beta)}{2}$ or on the parabolic law $4xy = (x + y)^2 - (x - y)^2$ or direct multipliers of a more general application. The design procedure is given, and as examples some indirect square law multipliers have been built, experimental results being presented. Figures obtained from two different circuits showed an error of less than 1 percent of the maximum value.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) DIFFERENTIAL PERFORMANCE REDUCTION METHODS FOR TURBO-PROPELLER AIRCRAFT. K. J. Lush. May 6, 1953. 16p. 2 tabs. (AAEE/Res/275)

Reduction methods for level speed, climb, and fuel consumption tests have been derived, which are, in the absence of compressibility effects, suitable for use with turbopropeller aircraft at the present stage. The methods require individual treatment of the particular engine installation, as they deal only with the reduction equation which would result from any given engine behavior. Numerical generalization about engine behavior did not seem worth while at the present stage, but simplifying generalizations are briefly discussed, which might become possible when experience is gained, and the simplifying assumptions are indicated.

N-23831*

Royal Aircraft Establishment (Gt. Brit.)
PILOT ESCAPE FROM SPINNING AIRCRAFT. T. H. Kerr. December 1952. 24p. photos. (RAE Tech. Note Aero 2199)

A series of pilot escape tests from models of elementary and advanced trainers, and fighter aircraft in the spin are presented. Escapes were made from varying points relative to the wing chord, on the inboard and outboard sides of the spin. The analyzed results show that if the pilot requires to bail out from a spinning aircraft, it is best to leave on the outboard side of the aircraft and in the crouching attitude. In this condition, it is most probable that he will clear the aircraft cleanly and be outside the spiral flight path within a half turn of the spin. If he bails out on the inboard side, his flight path will probably be through or very near the propeller disk and it will probably take at least two turns of the spin for him to clear the helical flight path of the aircraft.

Massachusetts Inst. of Tech.
A RADIATION THERMOMETER FOR METEOROLOGICAL USE. J. C. Johnson. March 15, 1953. 43p. diagrs., photos., 3 tabs. (Massachusetts Inst. of Tech.)

The theory, design, and construction of an infrared pyrometer calibrated as a thermometer is described. The instrument is termed a radiation thermometer. The radiation thermometer utilizes the 14.7μ band of radiation from the carbon dioxide always present in air as an indicator of free air temperature. The principle, though successful, averages the radiation over a path of the order of 2 miles. Because of this, the temperature measurement obtained will have limited significance. The same instrument will measure the temperature in the interior of clouds, averaging over a path whose length is of the order of the visual range. It is in this capacity that the radiation thermometer may be most useful.

DECLASSIFIED NACA REPORTS

NACA RM A7K03

LOW-SPEED INVESTIGATION OF A SMALL TRIANGULAR WING OF ASPECT RATIO 2.0. I - THE EFFECT OF COMBINATION WITH A BODY OF REVOLUTION AND HEIGHT ABOVE A GROUND PLANE. Leonard M. Rose. August 27, 1948. 41p. diagrs., photos., 7 tabs. (NACA RM A7K03) (Declassified from Restricted, 6/11/53)

Tests were made of triangular wing of aspect ratio 2.0 with a symmetrical double-wedge section with a maximum thickness of 5 percent of the chord. Results are presented for the wing alone and in two locations on a body of fineness ratio 12.5. Further data are also presented for the wing at several heights above a ground plane.

NACA RM A7K05

TESTS OF A TRIANGULAR WING OF ASPECT RATIO 2 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. I - THE EFFECT OF REYNOLDS NUMBER AND MACH NUMBER ON THE AERODYNAMIC CHARACTERISTICS OF THE WING WITH FLAP UNDEFLECTED. George G. Edwards and Jack D. Stephenson. January 22, 1948. 42p. diagrs., photos. (NACA RM A7K05) (Declassified from Restricted, 6/11/53)

This report presents results of tests of a semispan model of a wing having a triangular plan form, an aspect ratio of 2, and a double-wedge uncambered airfoil section with the maximum thickness at 20 percent of the chord. The effects of the addition of a fuselage and of minor modifications to the airfoil section were investigated. Aerodynamic characteristics of the model are presented for a range of Reynolds numbers from 5,000,000 to 27,500,000 at 0.18 Mach number and for a range of Mach number from 0.18 to 0.95 at 5,300,000 Reynolds number. Change in Reynolds number had little effect, and increasing the Mach number to the highest obtainable in the tunnel did not introduce sudden or abrupt changes in the wing characteristics.

NACA RM A7L05

AN INVESTIGATION OF THE DOWNWASH AND WAKE BEHIND LARGE-SCALE SWEPT AND UNSWEPT WINGS. William H. Tolhurst, Jr. February 2, 1948. 25p. diagrs., photo. (NACA RM A7L05) (Declassified from Restricted, 6/11/53)

This report contains the results of an investigation to determine, at large scale, the downwash and wake behind wings of 0°, $\pm 30^{\circ}$, and $\pm 45^{\circ}$ of sweep. The results include contour maps of downwash angle in a vertical plane located at a distance behind the wing approximating a normal tail position, and the spanwise variation of wake limits and pressure losses in the wake for several angles of attack.

NACA RM A8D02

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63° - INVESTIGATION OF A LARGE-SCALE MODEL AT LOW SPEED. Gerald M. McCormack and Walter C. Walling. January 21, 1949. 20p. diagrs., photos. (NACA RM A8D02) (Declassified from Restricted, 6/29/53)

Aerodynamic characteristics are presented for the wing alone and for the wing-fuselage combination. Experimental results are compared with characteristics predicted theoretically. The relationships between the aerodynamic characteristics and flow conditions existing over the wing are discussed.

NACA RM A8D27

WIND-TUNNEL INVESTIGATION OF TRANSONIC AILERON FLUTTER OF A SEMISPAN WING MODEL WITH AN NACA 23013 SECTION. Angelo Perone and Albert L. Erickson. July 12, 1948. 23p. diagrs., photos., tab. (NACA RM A8D27) (Declassified from Confidential, 6/11/53)

An investigation of aileron flutter with one degree of freedom up to 0.822 Mach number on a wing with an NACA 23013 section and the effect of wing-tip relief in alleviating aileron flutter are discussed. The beneficial effect of a low aileron-span-to-wing-span ratio is considered. The agreement that existed between the predicted and the actual flutter frequency was sufficient to indicate that sections of the type tested will not alter the existing recommendations for flutter analysis.

NACA RM A8E03

TESTS OF A TRIANGULAR WING OF ASPECT RATIO 2 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. II - THE EFFECTIVENESS AND HINGE MOMENTS OF A CONSTANT-CHORD PLAIN FLAP. Jack D. Stephenson and Arthur R. Amuendo. September 21, 1948. 82p. diagrs., photos., 9 tabs. (NACA RM A8E03) (Declassified from Restricted, 6/11/53)

This report presents the results of tests of a semispan model of a triangular wing having an aspect ratio of 2. The effects of deflecting a constant-chord plain flap were investigated for a Mach number range from 0.18 to 0.95 at a Reynolds number of 5,300,000 and at low speed for a Reynolds number range from 5,300,000 to 15,000,000. The data have been used in the calculation of some longitudinal characteristics of a triangular-wing tailless airplane. Increasing the Mach number from 0.18 to 0.95 caused systematic increases in longitudinal stability, lift, and control effectiveness, and algebraic decreases in the hinge-moment coefficients. Little effect due to variation in Reynolds number or to minor modifications of the airfoil section was noted.

NACA RM A8H03

SOME PRELIMINARY RESULTS IN THE DETERMINATION OF AERODYNAMIC DERIVATIVES OF CONTROL SURFACES IN THE TRANSONIC SPEED RANGE BY MEANS OF A FLUSH-TYPE ELECTRICAL PRESSURE CELL. Albert L. Erickson and Robert C. Robinson. October 8, 1948. 40p. diagrs., photos., 3 tabs. (NACA RM A8H03) (Declassified from Confidential, 6/11/53)

A method of measuring fluctuating aerodynamic forces by using electrical pressure cells is presented along with the analysis of one cycle of motion of a control surface during transonic flutter with one degree of freedom. The report shows the differences between upper- and lower-surface hinge moments and explains these differences to some extent.

NACA RM A9B17

CHORDWISE AND SPANWISE LOADINGS MEASURED AT LOW SPEED ON LARGE TRIANGULAR WINGS. Adrien E. Anderson. April 19, 1949. 78p. diagrs., photos., 2 tabs. (NACA RM A9B17) (Declassified from Restricted, 6/11/53)

Pressure distributions have been obtained from three triangular wing models: a wing-alone model having an aspect ratio of 2.04 and a modified double-wedge airfoil section; the same wing combined with a body of fineness ratio 12.5; and a mock-up of a triangular wing airplane which had an aspect ratio of 2.31 and an NACA 65-006.5 airfoil section. Pressure data were obtained through an angle-of-attack range at zero angle of sideslip. Chordwise pressure distribution, section lift characteristics, section centers of pressure, and span load distribution are presented.

NACA RM A9D04

FLIGHT INVESTIGATION OF THE EFFECT OF BOUNDARY-LAYER SUCTION ON PROFILE-DRAG COEFFICIENT AT SUPERCRITICAL MACH NUMBERS. Richard B. Skoog. September 20, 1949. 30p. diagrs., photos. (NACA RM A9D04) (Declassified from Confidential, 6/29/53)

Results of flight tests to study at high Reynolds number the effect of boundary-layer removal aft of the shock wave on airfoil drag at supercritical Mach numbers showed that no measurable effect of the suction existed for the available suction coefficient even though separation was present. The drag increase with Mach number was due primarily to pressure changes associated with supersonic flow on upper and lower surfaces which resulted in increased pressure drag.

NACA RM A9G13

TESTS OF A MODEL HORIZONTAL TAIL OF ASPECT RATIO 4.5 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. I - QUARTER-CHORD LINE SWEPT BACK 35°. Bruce E. Tinling and Jerald K. Dickson. September 9, 1949. 118p. diagrs., photo., tab. (NACA RM A9G13) (Declassified from Restricted, 6/11/53)

This report presents results of tests of a semispan model of a horizontal tail of aspect ratio 4.5 with the quarter-chord line swept back 35°; the NACA 64A010 airfoil section; and a plain, sealed elevator with tab. The Reynolds number was varied from 2,000,000 to 11,000,000 at a Mach number of 0.21 and Mach number was varied from 0.21 to 0.94 at a Reynolds number of 2,000,000. Lift, drag, pitching moment, elevator hinge moment, streamwise distribution of static pressure at the mid-semispan, tab effectiveness, tab hinge moment, and pressure difference across the elevator-nose seal were measured.

NACA RM A9G18

EFFECTS OF SYSTEMATIC CHANGES OF TRAILING-EDGE ANGLE AND LEADING-EDGE RADIUS ON THE VARIATION WITH MACH NUMBER OF THE AERODYNAMIC CHARACTERISTICS OF A 10-PERCENT-CHORD-THICK NACA AIRFOIL SECTION. James L. Summers and Donald J. Graham. September 26, 1949. 81p. diagrs., photos., 9 tabs. (NACA RM A9G18) (Declassified from Restricted, 6/11/53)

The effects of systematic changes in trailing-edge angle and leading-edge radius on the variation with Mach number of the aerodynamic characteristics of a 10-percent-chord-thick symmetrical NACA airfoil section are evaluated from wind-tunnel tests at Mach numbers from 0.3 to 0.9. Reductions in both parameters are shown to be beneficial to the section lift-curve slope at Mach numbers below that for the lift break, and to the maximum section lift coefficient at Mach numbers above 0.7 and detrimental to the drag-divergence Mach number at low section lift coefficients.

NACA RM A9H04

AN INVESTIGATION AT LOW SPEED OF A LARGE-SCALE TRIANGULAR WING OF ASPECT RATIO TWO. III. CHARACTERISTICS OF WING WITH BODY AND VERTICAL TAIL. Adrien E. Anderson. October 14, 1949. 96p. diagrs., photos., 3 tabs. (NACA RM A9H04) (Declassified from Restricted, 6/11/53)

An investigation has been made to determine the aerodynamic characteristics in sideslip of a triangular wing of aspect ratio 2.04 in combination with a body of fineness ratio 12.5 and a vertical tail surface. Force and moment data were obtained at several angles of sideslip for various configurations of constant-chord split flaps, semispan split-flap-type ailerons and a constant-chord rudder. The Reynolds number was 15.4×10^6 and the Mach number 0.13.

NACA RM A9H11a

TESTS OF A MODEL HORIZONTAL TAIL OF ASPECT RATIO 4.5 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. II - ELEVATOR HINGE LINE NORMAL TO THE PLANE OF SYMMETRY. Bruce E. Tinling and Jerald K. Dickson. October 17, 1949. 106p. diagrs., photo., tabs. (NACA RM A9H11a) (Declassified from Restricted, 6/11/53)

This report presents results of tests of a semispan model of a horizontal tail of aspect ratio 4.5 with the hinge line normal to the plane of symmetry; the NACA 64A010 airfoil section; and a plain, sealed elevator with tab. The Reynolds number was varied from 2,000,000 to 11,000,000 at a Mach number of 0.21 and the Mach number was varied from 0.21 to 0.88 at a Reynolds number of 2,000,000. Lift, drag, pitching moment, elevator hinge moment, chordwise distribution of static pressure at the mid-semispan, tab effectiveness, tab hinge moment, and pressure difference across the elevator-nose seal were measured. Results are compared to those of a previous investigation of a model which differed primarily in that its quarter-chord line had 35° of sweepback.

NACA RM A9K02a

EFFECTS OF BOUNDARY-LAYER CONTROL ON THE LONGITUDINAL CHARACTERISTICS OF A 45° SWEPT-FORWARD WING-FUSELAGE COMBINATION. Gerald M. McCormack and Woodrow L. Cook. February 2, 1950. 73p. diagrs., photo., 2 tabs. (NACA RM A9K02a) (Declassified from Restricted, 6/29/53)

An investigation has been conducted to determine the benefits obtainable by applying boundary-layer control to a 45° sweptforward wing-fuselage combination. Force and pressure-distribution data are presented for the model with and without boundary-layer control with leading-edge and trailing-edge flaps. The results showed that with suction applied through a slot at the wing-fuselage juncture separation could be postponed from a lift coefficient between 30 and 50 percent of the maximum to a lift coefficient between 78 and 93 percent of the maximum.

NACA RM A9K02b

A DESIGN STUDY OF LEADING-EDGE INLETS FOR UNSWEPT WINGS. Robert E. Dannenberg. June 30, 1950. 56p. diagrs., photos., 3 tabs. (NACA RM A9K02b) (Declassified from Restricted, 6/11/53)

A method is presented for calculating the profile coordinates for an inlet to be placed in the leading edge of an airfoil from formulas. The method includes an application of the principles of thin-airfoil theory which permits the change in velocity distribution caused by a variation in inlet profile to be calculated. Wind-tunnel tests of leading-edge inlets in an airfoil having the NACA 63_1-012 section were made to evaluate the effects of the inlets on the aerodynamic characteristics of the airfoil. The results indicated that the airfoil with an inlet devised by the design method had satisfactory aerodynamic characteristics.

NACA RM A50D04

EFFECTS OF LEADING-EDGE RADIUS AND MAXIMUM THICKNESS-CHORD RATIO ON THE VARIATION WITH MACH NUMBER OF THE AERODYNAMIC CHARACTERISTICS OF SEVERAL THIN NACA AIRFOIL SECTIONS. Robert E. Berggren and Donald J. Graham. July 3, 1950. 65p. diagrs., 7 tabs. (NACA RM A50D04) (Declassified from Restricted, 6/11/53)

The results of a wind-tunnel investigation at Mach numbers to approximately 0.9 and Reynolds numbers from 1×10^6 to 2×10^6 indicate no significant effects of leading-edge-radius variation on the variation with Mach number of the aerodynamic characteristics of 4- and 6-percent-chord-thick NACA 4-digit-series airfoil sections. The results indicate beneficial effects of maximum thickness reduction on lift and drag characteristics and no important effects on moment characteristics.

NACA RM A50E02

PRESSURE-DISTRIBUTION AND RAM-RECOVERY CHARACTERISTICS OF NACA SUBMERGED INLETS AT HIGH SUBSONIC SPEEDS. Joseph L. Frank. July 7, 1950. 41p. diagrs., photo. (NACA RM A50E02) (Declassified from Confidential, 6/11/53)

Presented are results of tests of NACA submerged inlets at four fuselage stations on a model of a hypothetical fighter airplane. Ram-recovery ratios were generally maximum for mass-flow ratios between 0.60 and 0.80. The inlet in the most forward position provided the highest ram recovery for almost all test conditions. Inlets in the region of high-velocity flow induced by the wing had compressibility losses beginning at 0.70 Mach number.

NACA RM E7K19

PRELIMINARY INVESTIGATION OF CONE-TYPE DIFFUSERS DESIGNED FOR MINIMUM SPILLAGE AT INLET. Roger W. Luidens and Henry Hunczak. May 3, 1948. 31p. photos., diagrs. (NACA RM E7K19) (Declassified from Confidential, 6/11/53)

Presents an investigation at a Mach number of 1.85 of cone-type diffuser designed for minimum spillage at the inlet. Pressure recoveries of stationary-cone configurations are presented as functions of cone angle, outlet-inlet area ratio, throat length, and angle of attack. Pressure recoveries of a 30° movable-cone configuration are presented as functions of contraction ratio and outlet-inlet area ratio. Stabilization of the normal shock within the diffuser by use of perforations is experimentally verified.

NACA RM E7L05

ANALYTICAL INVESTIGATION OF DISTRIBUTION OF CENTRIFUGAL STRESSES AND THEIR RELATION TO LIMITING OPERATING TEMPERATURES IN GAS-TURBINE BLADES. Richard H. Kemp and William C. Morgan. April 12, 1948. 25p. photo., diagrs. (NACA RM E7L05) (Declassified from Restricted, 6/11/53)

The distribution of centrifugal stresses at maximum operating conditions are presented for six turbine-blade designs and the limitation imposed on the permissible centrifugal stresses by the operating temperatures is discussed. It was found that this temperature limitation was important. In the case of one blade, several recorded surface failures have occurred in the region indicated as critical by this analysis.

NACA RM E8A26

FREE-FLIGHT INVESTIGATION OF 16-INCH-DIAMETER SUPERSONIC RAM-JET UNIT. George F. Kinghorn and John H. Disher. May 28, 1948. 20p. diagrs., photos. (NACA RM E8A26) (Declassified from Confidential, 6/11/53)

In order to determine the performance of ram-jet units in flight at supersonic speeds and to study methods for improving the performance, an investigation of a series of 16-inch-diameter ram-jet engines is being conducted in free flight. Supersonic flight speeds are obtained by releasing the unit from an airplane at an altitude of approximately 30,000 feet and allowing the engine thrust and the force of gravity to accelerate the unit.

NACA RM E8H03

COOLING OF GAS TURBINES. IX - COOLING EFFECTS FROM USE OF CERAMIC COATINGS ON WATER-COOLED TURBINE BLADES. W. Byron Brown and John N. B. Livingood. October 13, 1948. 26p. diagrs. (NACA RM E8H03) (Declassified from Restricted, 6/11/53)

Calculations of the effect of a ceramic coating on blade-metal and gas temperatures are prepared and comparisons of these effects with the changes produced by moving the cooling passages nearer the trailing edge are made. Results indicate that very low-conductivity ceramics, such as mica and porcelain, or material with similar conductivities, must be used to secure practical results.

NACA RM E8K05

PRESSURE DISTRIBUTIONS ON THIN CONICAL BODY OF ELLIPTIC CROSS SECTION AT MACH NUMBER 1.89. Stephen H. Maslen. January 20, 1949. 18p. diagrs., photo. (NACA RM E8K05) (Declassified from Confidential, 6/11/53)

Experimental pressure distributions at Mach number 1.89 are presented for a conical body of elliptic cross section. Data are presented for range of angles of yaw from -16° to 16° and angles of attack from -10° to 10°. Over the entire range of calculations, linearized theory checked closely with experiment.

NACA RM E50B02

CHARACTERISTICS OF PERFORATED DIFFUSERS AT FREE-STREAM MACH NUMBER 1.90. Henry R. Hunczak and Emil J. Kremzier. May 8, 1950. 69p. diagrs., photos. (NACA RM E50B02) (Declassified from Confidential, 6/11/53)

An investigation was conducted at Mach number 1.90 to determine pressure recovery and mass-flow characteristics of series of perforated convergent-divergent supersonic diffusers. Pressure recoveries as high as 96 percent were obtained, but at reduced mass flows through the diffuser. Theoretical considerations of effect of perforation distribution on shock stability in converging section of diffuser are presented and correlated with experimental data. A method of estimating relative importance of pressure recovery and mass flow on internal thrust coefficient basis is given and a comparison of various diffusers investigated is made.

NACA RM E50H22

EFFECT OF RAM-JET PRESSURE PULSATIONS ON SUPERSONIC-DIFFUSER PERFORMANCE. James F. Connors. November 20, 1950. 29p. photos., diagrs. (NACA RM E50H22) (Declassified from Confidential, 6/11/53)

Experimental study of effects of combustion roughness and controlled mechanical oscillations on diffuser operation was conducted on an 8-inch ram jet at Mach number 1.87. Within experimental accuracy, the optimum mean combustion-chamber static pressure occurred when the maximum instantaneous static pressure equalled the optimum steady-flow value and the corresponding decrement in optimum mean static pressure was equal to one-half the total amplitude of the pressure pulsations. A marked attenuation of amplitude of cold-buzz pressure fluctuations was effected over limited range of subcritical diffuser operation by means of properly tuned rotating disk located in combustion chamber.

NACA RM E50K07

AN INVESTIGATION OF CONVERGENT-DIVERGENT DIFFUSERS AT MACH NUMBER 1.85. DeMarquis D. Wyatt and Henry R. Hunczak. February 2, 1951. 60p. diagrs., photos., tab. (NACA RM E50K07) (Declassified from Restricted, 6/11/53)

Total-pressure recoveries and internal static-pressure distributions for a series of convergent-divergent supersonic diffusers operating at a Mach number of 1.85 are presented. The effect of inserting a cylindrical section between the supersonic inlet and the subsonic diffuser on shock stability is experimentally determined.

NACA RM E51B10

THE USE OF PERFORATED INLETS FOR EFFICIENT SUPERSONIC DIFFUSION. John C. Evvard and John W. Blakey. (Revised) April 13, 1951. 36p. diagrs., photo. (NACA RM E51B10) (Declassified from Restricted, 6/11/53)

The use of wall perforations on supersonic diffusers to avoid the internal contraction-ratio limitation is described. Experimental results at a Mach number of 1.85 on a preliminary model of a perforated diffuser having a geometric internal contraction ratio of 1.49 (the isentropic value) are presented. A theoretical discussion of the flow coefficients as well as the size and the spacing of the perforations is also included. At angles of attack of 0°, 3°, and 5°, total-pressure recoveries of 0.931, 0.920, and 0.906, respectively, were obtained.

NACA RM E51B13

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF ADDITIVE DRAG. Merwin Sibulkin. May 21, 1951. 33p. diagrs. (NACA RM E51B13) (Declassified from Confidential, 6/11/53)

The significance of additive drag is discussed and equations for determining its approximate value are derived. Charts are presented giving values of additive drag for open-nose inlets and for annular-nose inlets with conical flow at the inlet. The effects of variable inlet total-pressure recovery and static pressures on the center body are investigated, and an analytical method of predicting the variation of pressure on the center body with mass-flow ratio is given. Experimental values of additive drag are compared with values predicted by the methods presented.

NACA RM L7G09

INVESTIGATION OF HIGH-LIFT AND STALL-CONTROL DEVICES ON AN NACA 64-SERIES 42° SWEPTBACK WING WITH AND WITHOUT FUSELAGE. Robert R. Graham and D. William Conner. October 14, 1947. 47p. diagrs., photos., 2 tabs. (NACA RM L7G09) (Declassified from Restricted, 6/25/53)

Contains low speed, high Reynolds number characteristics of a 42° sweptback wing with aspect ratio 4 and NACA 64-series sections tested with various combinations of high-lift and stall-control devices and a fuselage. Combinations of outboard leading-edge flaps or slats with inboard split flaps substantially increased the maximum lift coefficient while maintaining longitudinally stable characteristics at the stall. Neither upper-surface fences nor outboard upper-surface split flaps were effective in improving longitudinal stability for those combinations where sizeable positive pitching-moment increases occurred beyond the stall.

NACA RM L7J20

INITIAL FLIGHT TESTS OF THE NACA FR-2, A HIGH-VELOCITY ROCKET-PROPELLED VEHICLE FOR TRANSONIC FLUTTER RESEARCH. J. G. Barmby and J. M. Teitelbaum. March 4, 1948. 21p. diagrs., photos. (NACA RM L7J20) (Declassified from Restricted, 6/11/53)

The initial flight tests of two simplified flutter vehicles, which were launched at the Langley Pilotless Aircraft Research Station at Wallops Island, Va., are described in this report. The results of the tests are in agreement with the results of the freely-falling-body test in that the wing failures in the transonic range occurred at velocities greater than the flutter velocity calculated from the two-dimensional, incompressible theory. Although the simple bread-wire system seems satisfactory for exploratory tests, the scope of the investigation could be ex-

tended by use of a frequency-recording telemeter. The use of high-velocity-rocket test vehicles of this type offers promise for flutter testing in the transonic and the supersonic regions.

NACA RM L7K06

TWO-DIMENSIONAL WIND-TUNNEL INVESTIGATION AT HIGH REYNOLDS NUMBERS OF AN NACA 65A006 AIRFOIL WITH HIGH-LIFT DEVICES. Robert J. Nuber and Stanley M. Gottlieb. February 4, 1948. 28p. diagrs., photos., tab. (NACA RM L7K06) (Declassified from Restricted, 6/29/53)

An investigation was made of an NACA 65A006 airfoil equipped with high-lift devices consisting of a 0.15-chord drooped-nose flap and a 0.20-chord plain trailing-edge flap. The airfoil section lift, pitching-moment, and drag characteristics, obtained at high Reynolds numbers and low Mach numbers ($M \leq 0.14$) with the flaps deflected individually and simultaneously, are presented.

NACA RM L8D29

WIND-TUNNEL INVESTIGATION OF HIGH-LIFT AND STALL-CONTROL DEVICES ON A 37° SWEPTBACK WING OF ASPECT RATIO 6 AT HIGH REYNOLDS NUMBERS. William Koven and Robert R. Graham. September 2, 1948. 70p. diagrs., photos., tab. (NACA RM L8D29) (Declassified from Restricted, 6/29/53)

Stall-control devices including an extensible round-nose leading-edge flap, a leading-edge slat, and a drooped leading edge were investigated; half- and full-span trailing-edge split and double slotted flaps were also investigated on the plain wing and in combination with the leading-edge devices. Force and moment data and stall studies are presented for all configurations; downwash and dynamic-pressure measurements are given for one combination of slat and double slotted flap. Typical plots of variation of spanwise position of load centroid with lift coefficient are included.

NACA RM L8E18

THE EFFECT OF BOUNDARY-LAYER CONTROL BY SUCTION AND SEVERAL HIGH-LIFT DEVICES ON THE LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A 47.5° SWEPTBACK WING-FUSELAGE COMBINATION. Jerome Pasamanick and Anthony J. Proterra. November 4, 1948. 44p. diagrs., photo., 2 tabs. (NACA RM L8E18) (Declassified from Restricted, 6/29/53)

An investigation has been made in the Langley full-scale tunnel of a 47.5° sweptback wing-fuselage combination equipped for boundary-layer control by suction. The wing aspect ratio was 3.5, the taper ratio was 0.5, and the airfoil sections normal to the quarter-chord line were NACA 64_1-A112. The wing configurations tested included the wing with various combinations of extensible leading-edge and split flaps. The effect of Reynolds number, suction-slot location, and suction flow coefficient on the aerodynamic characteristics was determined for the model at zero yaw over a range of angle of attack.

NACA RM L8E21

THE EFFECT OF BOUNDARY-LAYER CONTROL BY SUCTION AND OF SEVERAL HIGH-LIFT DEVICES ON THE AERODYNAMIC CHARACTERISTICS IN YAW OF A 47.5° SWEPTBACK WING-FUSELAGE COMBINATION. Jerome Pasamanick. October 28, 1948. 36p. diagrs., photo. (NACA RM L8E21) (Declassified from Restricted, 6/29/53)

An investigation has been made in the Langley full-scale tunnel of a 47.5° sweptback wing-fuselage combination equipped for boundary-layer control by suction. The wing aspect ratio was 3.5, the taper ratio was 0.5, and the airfoil sections normal to the quarter-chord line were NACA 64_1-A112. Tests included the plain wing and the wing with various combinations of extensible leading-edge and split flaps. The investigation was made to determine the effect of boundary-layer control by suction on the aerodynamic characteristics in yaw and on the effectiveness of a split-flap-type aileron for a range of angle of attack and suction-flow coefficient at a Reynolds number of 4.2×10^6 corresponding to a Mach number of approximately 0.07.

NACA RM L8J29

PRESENT STATUS OF RESEARCH ON BOUNDARY-LAYER CONTROL. Albert E. von Doenhoff and Laurence K. Loftin, Jr. January 12, 1949. 40p. diagrs. (NACA RM L8J29) (Declassified from Confidential, 6/29/53)

A survey has been made of the present status of boundary-layer control and its applications in aeronautics. The possible improvements in airplane characteristics resulting from boundary-layer control are discussed and the general lines of future research are indicated.

NACA RM L9B04

HYDRODYNAMIC CHARACTERISTICS OF AERODYNAMICALLY REFINED PLANING-TAIL HULLS. Robert McKann and Claude W. Coffee. March 28, 1949. 41p. diagrs., photos. (NACA RM L9B04) (Declassified from Confidential, 6/11/53)

The hydrodynamic characteristics of two aerodynamically refined planing-tail hulls were determined from dynamic model tests in Langley tank no. 2. Stable take-offs could be made for a wide range of location of the center of gravity. The lower porpoising limit was high but no upper limit was encountered. The hump load-resistance ratios were low. Stable landings were made at the center-of-gravity locations tested for a wide range of contact trim.

NACA RM L9D15

HYDRODYNAMIC CHARACTERISTICS OF A SWEPT PLANING-TAIL HULL. Robert E. McKann, Claude W. Coffee and Donald D. Arabian. September 12, 1949. 34p. diagrs., photos., tab. (NACA RM L9D15) (Declassified from Confidential, 6/11/53)

The hydrodynamic characteristics of an aerodynamically refined swept planing-tail hull were determined from dynamic model tests in Langley tank no. 2. Acceptable propeller spray characteristics were obtained by the use of vertical spray strips. Stable take-offs could be made with a large range of elevator deflections and center-of-gravity location. Stable landings were made for a wide range of center-of-gravity location and contact trim. The hump load-resistance ratio was low.

NACA RM L9F08

AERODYNAMIC CHARACTERISTICS OF AN AIRFOIL-FOREBODY SWEPT FLYING-BOAT HULL WITH A WING AND TAIL SWEPT BACK 51.3° AT THE LEADING EDGE. Rodger L. Naeseth and Richard G. MacLeod. September 9, 1949. 27p. diagrs., photo., tab. (NACA RM L9F08) (Declassified from Confidential, 6/11/53)

Results of tests in the Langley 300 MPH 7- by 10-foot tunnel of an airfoil-forebody swept flying-boat hull mounted on a wing swept back 51.3° at the leading edge are presented. Aerodynamic characteristics of the hull (including wing interference) and longitudinal and lateral stability characteristics of the complete configuration (hull, wing, 51.3° sweptback tail) with stall-control devices and lift flaps are presented.

NACA RM L9G15

INVESTIGATION AT LARGE SCALE OF THE PRESSURE DISTRIBUTION AND FLOW PHENOMENA OVER A WING WITH THE LEADING EDGE SWEPT BACK 47.5° HAVING CIRCULAR-ARC AIRFOIL SECTIONS AND EQUIPPED WITH DROOPED-NOSE AND PLAIN FLAPS. Roy H. Lange, Edward F. Whittle, Jr. and Marvin P. Fink. September 8, 1949. 72p. diagrs., 3 tabs. (NACA RM L9G15) (Declassified from Restricted, 6/29/53)

The results of an investigation of the effects of drooped-nose-flap and plain-flap deflection on the pressure distribution over a wing with the leading edge swept back 47.5° and having symmetrical circular-arc airfoil sections conducted in the Langley full-scale tunnel at a Reynolds number of 4.3×10^6 and a Mach number of 0.07 are included in this paper. The configurations tested include the basic wing, the wing with a full-span drooped-nose flap, an inboard semispan plain flap, and a combination of these two flap configurations.

NACA RM L9H10

INVESTIGATION OF HIGH-SUBSONIC PERFORMANCE CHARACTERISTICS OF A 12° 21-INCH CONICAL DIFFUSER, INCLUDING THE EFFECTS OF CHANGE IN INLET-BOUNDARY-LAYER THICKNESS. Martin R. Copp and Paul L. Klevatt. March 24, 1950. 51p. diagrs., photos. (NACA RM L9H10) (Declassified from Restricted, 6/11/53)

An investigation of performance characteristics and boundary-layer growth of a 12° 21-inch conical diffuser over a Reynolds number range of 1.45×10^6 to 7.45×10^6 and a Mach number range of 0.11 to approximately choking are presented for two thicknesses of inlet boundary layer. The mean value, over the entire range of inlet velocities, of the displacement thickness of the thinner inlet boundary layer was approximately 0.035 inch and that of the thicker inlet boundary layer was approximately six times this value. Performance parameters, static-pressure distributions, and boundary-layer measurements are presented for both thicknesses of inlet boundary layer.

NACA RM L9K10

THE EFFECT OF THE INLET MACH NUMBER AND INLET-BOUNDARY-LAYER THICKNESS ON THE PERFORMANCE OF A 23° CONICAL-DIFFUSER - TAIL-PIPE COMBINATION. Jerome Persh. March 21, 1950. 53p. diagrs. (NACA RM L9K10) (Declassified from Restricted, 6/11/53)

An investigation was made of the effect of the inlet Mach number and entrance-boundary-layer thickness on the performance of a 23° 21-inch conical-diffuser - tail-pipe combination with a 2:1 area ratio over an inlet Mach number range of 0.17 to 0.89 and corresponding Reynolds numbers of 1,700,000 to 7,070,000. Performance coefficients, longitudinal static-pressure distributions, and the results of boundary-layer surveys made at six stations along the diffuser wall are presented.

NACA RM L50B15

FULL-SCALE INVESTIGATION OF BOUNDARY-LAYER CONTROL BY SUCTION THROUGH LEADING-EDGE SLOTS ON A WING-FUSELAGE CONFIGURATION HAVING 47.5° LEADING-EDGE SWEEP WITH AND WITHOUT FLAPS. Jerome Pasamanick and Thomas B. Sellers. April 5, 1950. 55p. diagrs., photo., 2 tabs. (NACA RM L50B15) (Declassified from Restricted, 6/29/53)

Presents results of the investigation in the Langley full-scale tunnel of leading-edge boundary-layer control by suction in combination with high-lift devices on a wing-fuselage configuration having 47.5° leading-edge sweep. The wing aspect ratio was 3.4, the taper ratio was 0.51, and the airfoil sections normal to the quarter-chord line were NACA 64_1A112. The data include the effects of suction-slot location and suction-flow quantities on the force measurements, visual-flow studies, and surface-pressure-distribution measurements at zero yaw over a range of angle of attack. Reynolds number effects were determined from 3.0×10^6 to 7.5×10^6 for the wing in the sealed and faired condition.

NACA RM L50C02a

HIGH-SUBSONIC PERFORMANCE CHARACTERISTICS AND BOUNDARY-LAYER INVESTIGATIONS OF A 12° 10-INCH-INLET-DIAMETER CONICAL DIFFUSER. B. H. Little, Jr. and Stafford W. Wilbur. May 11, 1950. 62p. diagrs., photos. (NACA RM L50C02a) (Declassified from Restricted, 6/11/53)

An investigation was made of the effect of inlet-boundary-layer thickness and Mach number on the performance of a 12° 10-inch-inlet-diameter conical diffuser of 2:1 area ratio. Inlet Mach number was varied from 0.2 to choking and Reynolds number (based on inlet diameter) from 1×10^6 to 3.9×10^6. Performance coefficients, static-pressure distributions, boundary-layer profiles at seven stations in the diffuser, and boundary-layer parameters are presented.

NACA RM L52G31

CALIBRATION OF STRAIN-GAGE INSTALLATIONS IN AIRCRAFT STRUCTURES FOR THE MEASUREMENT OF FLIGHT LOADS. T. H. Skopinski, William S. Aiken, Jr. and Wilber B. Huston. October 8, 1952. 71p. diagrs., 10 tabs. (NACA RM L52G31) (Declassified from Confidential, 6/29/53)

A general procedure is developed for calibrating strain-gage installations in aircraft structures for application to flight measurements of loads. The basic procedure can be modified as necessary to suit the requirements of any particular structure. The application of the procedure is illustrated by results for two typical structures.

CURRENT NACA REPORTS

NACA TN 2955

ESTIMATION OF FORCES AND MOMENTS DUE TO ROLLING FOR SEVERAL SLENDER-TAIL CONFIGURATIONS AT SUPERSONIC SPEEDS. Percy J. Bobbitt and Frank S. Malvestuto, Jr. July 1953. 71p. diagrs. (NACA TN 2955)

A method, based on conformal-transformation techniques, for solving two-dimensional boundary-value problems has been used to evaluate the velocity potentials, span loadings, pressure distributions, and associated stability derivatives for several slender-tail arrangements performing a steady rolling motion. Illustrative variations of the rolling stability derivatives for several series of tail shapes, as well as sample span loadings and pressure distributions, are included.

NACA TN 2967

AN ANALYSIS OF THE POWER-OFF LANDING MANEUVER IN TERMS OF THE CAPABILITIES OF THE PILOT AND THE AERODYNAMIC CHARACTERISTICS OF THE AIRPLANE. Albert E. von Doenhoff and George W. Jones, Jr. August 1953. 42p. diagrs. (NACA TN 2967)

A theoretical analysis of the power-off landing maneuver is presented in which an attempt is made to consider both the aerodynamic characteristics of the airplane and the human capabilities of the pilot. Certain factors are derived which allow for the variations in pilot judgment in a manner which is directly connected to pilot capabilities; however, future research is needed for the actual numerical evaluation of the factors. An analysis including these factors is set up by means of which the minimum length of landing field required for landing an airplane safely could be found.

NACA TN 2976

A STUDY OF THE STABILITY OF THE INCOMPRESSIBLE LAMINAR BOUNDARY LAYER ON INFINITE WEDGES. Neal Tetervin. August 1953. 41p. diagrs., 4 tabs. (NACA TN 2976)

Hartree's numerical solutions of the boundary-layer equations for the flow over infinite wedges are used to confirm a result previously obtained by the use of Schlichting's approximate method for the calculation of the laminar boundary layer; namely, that in a region of falling pressure a thick velocity profile can be more stable than a thin profile although the velocity at the edge of the boundary layer and the pressure gradient are the same for both profiles. The investigation also leads to the inference that the calculated effects of a change in boundary-layer thickness on the stability and on the local roughness Reynolds number should be essentially unchanged by replacing the Schlichting single-parameter family of velocity profiles by the Hartree single-parameter family of velocity profiles.

NACA TN 2980

THE AERODYNAMIC CHARACTERISTICS OF AN ASPECT-RATIO-20 WING HAVING THICK AIRFOIL SECTIONS AND EMPLOYING BOUNDARY-LAYER CONTROL BY SUCTION. Bennie W. Cocke, Jr., Marvin P. Fink and Stanley M. Gottlieb. August 1953. 63p. diagrs., photos., 2 tabs. (NACA TN 2980)

An investigation has been conducted to study the aerodynamic characteristics of an aspect-ratio-20 wing employing thick airfoil sections and boundary-layer control by suction. Data from models tested in the Langley full-scale tunnel and the Langley low-turbulence pressure tunnel are included in this report. The results indicate the effects of varying suction flow rate, suction-slot configuration, wing surface condition, flap deflection, and Mach number.

NACA TN 2982

SUPERSONIC FLOW PAST OSCILLATING AIRFOILS INCLUDING NONLINEAR THICKNESS EFFECTS. Milton D. Van Dyke. July 1953. 41p. diagrs. (NACA TN 2982)

A solution to second order in thickness is derived for harmonically oscillating two-dimensional airfoils in supersonic flow. For slow oscillations of an arbitrary profile, the result is found as a series including the third power of frequency. For arbitrary frequencies, the method of solution for any specific profile is indicated, and the explicit solution derived for a single wedge. Nonlinear thickness effects are found generally to reduce the torsional damping, and so enlarge the range of Mach numbers within which torsional instability is possible.

NACA TN 2985

A FLIGHT INVESTIGATION OF THE EFFECT OF STEADY ROLLING ON THE NATURAL FREQUENCIES OF A BODY-TAIL COMBINATION. Norman R. Bergrun and Paul A. Nickel. August 1953. 27p. diagrs., photo., 2 tabs. (NACA TN 2985)

Flight data have been obtained with a freely falling body-tail combination to show the effects of steady

rolling on the response in the pitching and yawing motions. Observed effects are compared with those predicted by theory, and reasonably good agreement is obtained. Charts are also presented to provide a rapid means for estimating the effective values of the stability derivatives C_{m_α} and C_{n_β} under steady rolling conditions.

NACA TN 2988

TEMPERATURES, THERMAL STRESS, AND SHOCK IN HEAT-GENERATING PLATES OF CONSTANT CONDUCTIVITY AND OF CONDUCTIVITY THAT VARIES LINEARLY WITH TEMPERATURE. S. V. Manson. July 1953. 62p. diagrs. (NACA TN 2988)

Working formulas are presented for the steady-state temperatures and thermal stress in heat-generating infinite plates of constant conductivity, and of conductivity that decreases linearly with temperature as the temperature increases, for the case in which the heat is generated uniformly throughout the plate thickness and both faces of the plate are equally cooled. A criterion is indicated for determining the surface cooling conditions under which the thermal shocks at the surface and midplane will be smaller than, equal to, or greater than the steady-state thermal stresses at those planes. The dimensionless parameters governing the transient temperatures and thermal stresses in materials of linearly varying conductivity are derived by a similarity study of the conduction equation and boundary conditions of the transient state. A numerical technique for solving the transient-state equations is indicated in detail.

NACA TN 2989

COMPARISON OF SECONDARY FLOWS AND BOUNDARY-LAYER ACCUMULATIONS IN SEVERAL TURBINE NOZZLES. Milton G. Kofskey, Hubert W. Allen and Howard Z. Herzig. August 1953. 58p. diagrs., photos., 3 tabs. (NACA TN 2989)

An investigation was made of losses and secondary flows in three different turbine nozzle configurations in annular cascades. Appreciable outer shroud loss cores (passage vortices) were found to exist at the discharge of blades which had thickened suction surface boundary layers near the outer shroud. Blade designs having thinner boundary layers did not show such outer shroud loss cores, but indicated greater inward radial flow of low momentum air in the blade wake which resulted in greater contribution to inner shroud loss regions. The blade wake was a combination of profile loss and low momentum air from the outer shroud, and the magnitude of the wake loss is to this extent an indication of the presence or absence of radial flow. At a higher Mach number, shock-boundary-layer thickening on the blade suction surfaces provided an additional radial flow path for low momentum air, which resulted in large inner shroud loss regions accompanied by large deviations from design values of discharge angle.

NACA TN 2992

APPLICATION OF A CHARACTERISTIC BLADE-TO-BLADE SOLUTION TO FLOW IN A SUPERSONIC ROTOR WITH VARYING STREAM-FILAMENT THICKNESS. Eleanor L. Costilow. August 1953. 36p. diagrs., 5 tabs. (NACA TN 2992)

An analysis of the circumferential blade-to-blade flow properties in a supersonic impeller has been made using the method of characteristics on an arbitrary stream surface of revolution. The method takes into account variable stream-filament thickness and curvature along the flow surface. The results of an example considering stream-filament-thickness variation alone indicate an appreciable difference between the flow properties calculated with the plane-flow characteristic equations and those determined with the characteristics method demonstrated here. The effect of a stream-filament-thickness reduction from blade-passage inlet to exit was to reduce the relative velocity and the absolute value of the flow angle in the blade passage.

NACA TN 2993

CALIBRATION OF STRAIN-GAGE INSTALLATIONS IN AIRCRAFT STRUCTURES FOR THE MEASUREMENT OF FLIGHT LOADS. T. H. Skopinski, William S. Aiken, Jr. and Wilber B. Huston. August 1953. 70p. diagrs., 10 tabs. NACA TN 2993. Formerly RM L52G31)

A general procedure is developed for calibrating strain-gage installations in aircraft structures for application to flight measurements of loads. The basic procedure can be modified as necessary to suit the requirements of any particular structure. The application of the procedure is illustrated by results for two typical structures.

NACA RM E53E28

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF SUPPORT INTERFERENCE ON THE PRESSURE DISTRIBUTION OF A BODY OF REVOLUTION AT A MACH NUMBER OF 3.12 AND REYNOLDS NUMBERS FROM 2×10^6 to 14×10^6. L. Eugene Baughman and John R. Jack. August 1953. 18p. diagrs., photo., tab. (NACA RM E53E28)

An experimental investigation was performed to determine the effect on base and forebody pressures of using a sting modified with varying length splitter plates and fins instead of a conventional sting to support a cone-cylinder body of revolution. The investigation was conducted at a Mach number of 3.12 for a Reynolds number range of 2×10^6 to 14×10^6 and for an angle of attack range of 0° to 9°. For Reynolds numbers of 8×10^6 and 14×10^6 there was a negligible effect of the splitter plate modification on the base pressure, and at a Reynolds number of 2×10^6 there was a small effect. Positioning the leading edge of the splitter plate at or ahead of the base made no appreciable change in the influence of the modifications on base pressure at a Reynolds number of 14×10^6. With the fin-type modification there was a small increase in base pressure.

NACA RM E53F02

PRELIMINARY RESULTS OF HEAT TRANSFER FROM A STATIONARY AND ROTATING ELLIPSOIDAL SPINNER. U. von Glahn. August 1953. 35p. diagrs., photo., 2 tabs. (NACA RM E53F02)

The convective heat-transfer coefficients were determined for an ellipsoidal spinner of 30-inch maximum diameter for both stationary and rotating operation. The range of conditions studied included airspeeds up to 275 miles per hour, rotational speeds up to 1200 rpm, and angles of attack of zero and 4°. The results indicate that a higher heat transfer occurred with rotation of the spinner. Transition from laminar to turbulent flow occurred over a large range of Reynolds numbers primarily because of surface roughness of the spinner.

FUNCTION GENERATORS BASED ON LINEAR INTERPOLATION, WITH APPLICATIONS TO ANALOGUE COMPUTING. E. G. C. Burt and O. H. Lange. April 1953. 27p. diagrs. (RAE Tech. Note GW 244)

The use of function generators in electronic analogue computing and simulation greatly extends the range of problems which can be solved by these methods. This paper presents a technique in which diode units are used to approximate to the functions by linear interpolation. It is shown that the method can be extended to deal with a wide class of functions, including multivariate functions. Analogue multiplication and division are discussed as particular cases of function generators, and formulas for the general function are developed. The results are presented of an experimental generator for $\sin x$ in the range $-\pi \leq x \pi \leq$, in which the error is about 1 percent of the maximum output.

MOVING PARTIAL RANGE SMOOTHING WITH CENTRAL-DIFFERENCES USING A NATIONAL ACCOUNTING MACHINE. J. D. Downes. April 1953. 33p. diagrs., 12 tabs. (RAE Tech. Note GW 250)

Based on a suggestion by Dr. Th. W. Schmidt of G. W. Trials Division, a method of partial range smoothing of experimental data by central-differences which greatly reduces the normal amount of labor and permits simple checking, is described. The method is particularly suited for use where a National Accounting Machine as well as a desk calculator is available. The observed quantities are converted to linear combinations of their differences and used in an adaptation of the "least-squares" method of curve-fitting. Additional, relevant applications of the National Machine are included in numerical example.

THE APPLICATION OF THE POLYGON METHOD TO THE CALCULATION OF THE COMPRESSIBLE SUBSONIC FLOW ROUND TWO-DIMENSIONAL PROFILES. L. C. Woods. 1953. 31p. diagrs., 7 tabs. (ARC CP 115)

This paper describes the method now used by the author of applying the polygon method to the calculation of the compressible subsonic flow round two-dimensional airfoils. Tables have been constructed which can be used for all airfoil shapes, putting the polygon method on the same footing numerically with Goldstein's "Approximation III" for incompressible flow. A method of calculating lift and moment coefficients, and their rates of change with incidence is also given in the paper.

WAKE SURVEY AND STRAIN-GAUGE MEASUREMENTS ON AN INCLINED PROPELLER IN THE R. A. E. 24-FT. TUNNEL. PART I. WAKE SURVEY. J. G. Russell. 1953. 61p. diagrs., photos., 4 tabs. (ARC CP 117)

This report describes tests carried out in the RAE 24-foot wind tunnel with a 16 foot diameter, 4 bladed propeller, during October and November 1949. Wake survey and blade strain-gage measurements were made at tunnel speeds of 100 and 170 fps with the propeller axis inclined at angles of 0°, 5°, 10°, and 15° to the air flow. The blade angles and propeller rotational speeds were also varied within the limits imposed by the 1,500 hp electric motor. The lift grading curves at the points of maximum and minimum loading, derived from total head measurements made in the slipstream by means of a pilot comb, have been compared with estimated values, and estimated power absorption figures compared with measured values.

A COMPARISON OF CALCULATED AND MEASURED BASE PRESSURES OF CYLINDRICALLY BASED PROJECTILES. W. F. Cope. Appendix: CALCULATION OF REYNOLDS NUMBER EFFECT ON PROJECTILES AT SUPERSONIC SPEEDS. W. F. Cope. 1953. 12p. diagrs., photo. (ARC CP 118)

In 1946 at the VI International Congress for Applied Mechanics a paper was read on a method of calculating the base pressure of a cylindrically based projectile. At that time there were few written base pressure determinations and therefore it was not possible to check completely the theory put forward. Since that time measurements have been made. In this report these measurements are compared with results of calculations according to the theory. The original report, "Calculation of Reynolds Number Effect on Projectiles at Supersonic Speeds," is included as an appendix.

EFFECT OF MEAN STRESS ON THE FATIGUE STRENGTH OF D.T.D. 364 ROUND BARS WITH AND WITHOUT TRANSVERSE HOLES. G. M. Norris. 1953. 15p. photos., diagrs., 3 tabs. (ARC CP 120)

Endurance curves for zero mean stress and for tensile mean stresses of 5 tons/in^2 and 10 tons/in^2 were determined for round specimens machined from extruded D.T.D. 364 bar. Endurance curves were determined also for similar specimens with a transverse hole. Variations in surface roughness caused some scatter in results and an attempt is made to correlate degree of surface finish with fatigue strength.

Aeronautical Research Council (Gt. Brit.)
THE LOW SPEED PERFORMANCE OF A HELICOPTER. A. L. Oliver. 1953. 12p. diagrs. (ARC CP 122)

The analysis and estimation of helicopter performance is dependent upon the accurate assessment of rotor induced velocity. An empirical curve relating the flow through the rotor to the flight speed is used for vertical flight and the momentum theory is sufficiently accurate for a tip speed ratio greater than about 0.1, but no simple method has been generally available for the intermediary speed range. Sets of empirical curves covering this speed range and based on the analysis of low-speed flight performance are given in this report. The charts give values of the rotor induced velocity varying smoothly from the vertical flight state to the forward flight region in which the momentum theory becomes accurate. The charts are presented in forms suitable for determining steady flight performance and also for estimating rotor thrust during accelerated motion in, for example, take-off flight.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF CURVATURE OF SURFACE AND THICKNESS OF TRAILING EDGE ON AILERON HINGE MOMENTS. Part I. MODIFICATION TO AILERON ON UPPER SURFACE. A. S. Batson, C. H. Burge and J. R. Greening. Part II. MODIFICATION TO AILERON ON LOWER SURFACE. A. S. Batson, C. H. Burge and W. C. Skelton. Part III. MODIFICATION TO AILERON ON BOTH SURFACES. A. S. Batson, C. H. Burge and W. C. Skelton. 1953. 48p. diagrs., photo., 13 tabs. (ARC R & M 2506. Formerly ARC 5310; S & C 1257; ARC 5490; S & C 1290; ARC 6188; S & C 1426)

This investigation was made to provide additional data on the effect on hinge moment of rounding the upper surface and of thickening the trailing edge of an aileron. Hinge moments were measured on an aileron (24.6 percent balance), and on an aileron (27-1/2 percent balance) with various modifications to the upper surface, lower surface, and both surfaces. Strips (approximately 1 percent of aileron chord) were also fitted for a few cases near the trailing edges.

Aeronautical Research Council (Gt. Brit.)
THE THEORETICAL ESTIMATION OF POWER REQUIREMENTS FOR SLOT-SUCTION AEROFOILS, WITH NUMERICAL RESULTS FOR TWO THICK GRIFFITH TYPE SECTIONS. J. H. Preston, N. Gregory and A. G. Rawcliffe. 1953. 27p. diagrs. (ARC R & M 2577. Formerly ARC 10,280; Perf. 276; FM 1052; ARC 11,610; Perf. 466; FM 1263)

This report describes a method for assessing the performance of slot-suction airfoils in terms of an effective drag coefficient, which takes into account the power requirements of the suction pump neglecting slot entry and duct losses. When the suction-slot is located at a velocity discontinuity the suction flow

required to prevent separation can be calculated, using the elementary theory suggested by Sir Geoffrey Taylor. The method is applied to two Griffith type airfoils and the drags are compared with those of normal thin airfoils 20 percent thick.

ELECTRONICS APPLIED TO THE MEASUREMENT OF PHYSICAL QUANTITIES. G. E. Bennett, G. R. Richards and E. C. Voss. 1952. 124p. diagrs., photos. (ARC R & M 2627. Formerly RAE Instn. 1)

The report describes the application of electro-mechanical and electronic principles to the design of instruments for the measurement of physical quantities such as movement, strain, pressure, acceleration, and vibratory motion, with particular reference to the special requirements of aeronautical engineering. The dynamic characteristics of pick-ups are considered, and subdivided on an electrical basis into electromagnetic, capacitance and resistance types, a detailed description of each type being given. An account is given of the circuits used for the conversion of the electrical variation produced in each type of pick-up into a corresponding voltage or current, particular mention being made of bridge circuits and resonance circuit methods. The special requirements of amplifiers, and the best basic circuits for satisfying them, are considered and illustrated by detailed reference to a number of particular amplifier designs; in particular, direct-coupled and carrier amplifiers are considered. The requirements of recording equipment and the various recording methods are discussed, and a detailed account given of photographic recording and various oscillograph cameras, their optical arrangements, components and timing devices.

THE THERMODYNAMICS OF FRICTIONAL RESISTED ADIABATIC FLOW OF GASES THROUGH DUCTS OF CONSTANT AND VARYING CROSS SECTION. W. R. Thomson. September 1952. 45p. diagrs. (NGTE R.119)

The report presents an analytical study dealing with the adiabatic flow of gases with frictional losses through ducts of constant and varying cross section. The thermodynamic treatment is along lines published by other workers such as Bailey and Fabri and is essentially one-dimensional in character insofar that frictional effects are assumed to be uniformly distributed over the total cross-sectional area of flow. With this simplifying assumption, relationships are deduced connecting the pressure, temperature, velocity and flow area of the gas at any one plane with those at any other plane in a duct. The main relationships are unusable for quantitative estimation except through graphs and the main value of the report lies in the presentation of these graphs, the use of which should facilitate the solution of duct flow problems.

ON BOUNDARY LAYERS AND UPSTREAM INFLUENCE. I. A COMPARISON BETWEEN SUBSONIC AND SUPERSONIC FLOWS. M. J. Lighthill. October 23, 1952. 17p. diagrs., 3 tabs. (ARC 15,297; FM 1805)

It is pointed out that there are two separate mechanisms for upstream influence through the boundary layer in supersonic flow, and that one of these (that involving separation) operates also in subsonic flow. A quantitative theory of subsonic flow up a step is given to illustrate this. The main differences between the subsonic and supersonic flows are as follows. (1) The boundaries of dead air regions are nearly straight in supersonic flow but are usually highly curved in subsonic flow. (2) Separation (whether of the laminar or turbulent layer) occurs at a much lower pressure coefficient in supersonic flow; this is only slightly due to the fact that the fluid nearest the wall is then lighter and so more easily brought to rest; it is due much more to the relative suddenness of the pressue rise ahead of the dead air region. (3) However, for a given pressure coefficient in the dead air region, the distance of upstream influence is somewhat greater in the subsonic flow, except at the higher pressures.

A METHOD FOR MEASURING THE REACTION FORCE OF A HIGH PRESSURE GAS STREAM. P. J. Fletcher. March 1953. 9p. diagrs. (NGTE Memo. M. 184)

A method has been developed for measuring the reaction force produced by a high pressure gas stream. Briefly the method is to utilize the jet reaction to produce a bending moment in the gas supply pipe by arranging for the jet to discharge in a direction at right angles to that of the entering air. The strain due to bending is indicated by resistance strain gages and the reaction force deduced from direct calibration. The method thus obviates the need for flexible joints and hence eliminates the problem of ensuring flexibility and sensitivity at high pressure. A detailed description of the method of installing the gages is given as well as the precautions necessary

to separate the required bending strain from that due to pressure forces. With the particular apparatus described a thrust of up to 150 lb produced by a gas stream at 10 atm pressure can be measured to within $\pm$ 0.2 lb.

NACA TN 2965

AN ANALYSIS OF NORMAL-ACCELERATION AND AIRSPEED DATA FROM A FOUR-ENGINE TYPE OF TRANSPORT AIRPLANE IN COMMERCIAL OPERATION ON AN EASTERN UNITED STATES ROUTE FROM NOVEMBER 1947 TO FEBRUARY 1950. Thomas L. Coleman and Paul W. J. Schumacher. August 1953. 27p. diagrs., 5 tabs. (NACA TN 2965)

Normal acceleration and airspeed data covering about 50,000 hours of flight of one type of four-engine transport airplane flown in commercial operations at altitudes to 20,000 feet on a north-south route in the eastern United States are analyzed to determine the gusts encountered and the accelerations experienced. Comparisons are made between the present results and the results previously obtained from other operations. Effects of airpseed and of seasons on the gusts and accelerations are indicated.

NACA TN 2984

STUDIES OF THE LATERAL-DIRECTIONAL FLYING QUALITIES OF A TANDEM HELICOPTER IN FORWARD FLIGHT. Kenneth B. Amer and Robert J. Tapscott. August 1953. 42p. diagrs., photos., tab. (NACA TN 2984)

Results of flight measurements and pilots' opinions of the forward-flight lateral-directional flying qualities of a tandem helicopter in several different configurations are compared and analyzed. The conclusions are presented in the form of desirable flying-qualities goals applicable to all types of helicopters. Comparison between theoretical analyses and experimental results indicates theory to be a useful tool for studying means of achieving these goals. On the basis of theoretical analyses, possible practical methods of achieving these goals in the tandem helicopter are suggested.

NACA TN 2986

EFFECT OF BLADE-THICKNESS TAPER ON AXIAL-VELOCITY DISTRIBUTION AT THE LEADING EDGE OF AN ENTRANCE ROTOR-BLADE ROW WITH AXIAL INLET, AND THE INFLUENCE OF THIS DISTRIBUTION ON ALINEMENT OF THE ROTOR BLADE FOR ZERO ANGLE OF ATTACK. John D. Stanitz. August 1953. 33p. diagrs. (NACA TN 2986)

A method is developed for estimating the effect of blade-thickness taper on the inlet axial-velocity distribution of an entrance rotor-blade row with axial inlet, and the influence of this velocity distribution on the alinement of the rotor blade for zero effective angle of attack (that is, zero blade loading at the nose). This alinement of the blade requires a deviation between the angle of the blade camber line direction at the inlet and the upstream relative flow direction. The method is developed for compressible and incompressible nonviscous fluids, and results are presented for incompressible flow into a plane, two-dimensional cascade and for compressible flow into an entrance rotor-blade row with tapered blades. It is concluded that, for the entrance rotor-blade row investigated, blade taper has a large effect on the inlet deviation angle; whereas compressibility has a small effect, except perhaps at the hub, and the upstream relative flow direction also has a small effect.

NACA TN 2987

CHARTS RELATING THE COMPRESSIVE BUCKLING STRESS OF LONGITUDINALLY SUPPORTED PLATES TO THE EFFECTIVE DEFLECTIONAL AND ROTATIONAL STIFFNESS OF THE SUPPORTS. Roger A. Anderson and Joseph W. Semonian. August 1953. 53p. diagrs., 4 tabs. (NACA TN 2987)

The stability of a plate under edge compressive stress is analyzed in terms of the deflectional and rotational stiffnesses of one or more longitudinal lines of support between the plate side edges. The results are presented in the form of charts which make possible the determination of the compressive buckling stress of plates supported by members whose stiffness may or may not be defined by elementary beam bending and twisting theory but yet whose effective restraint is amenable to evaluation. The deflectional and rotational restraint provided by longitudinal stiffeners and full-depth webs is discussed, and numerical examples illustrate the application of the charts to the design of wing structures.

NACA TN 2990

FLIGHT MEASUREMENTS AND ANALYSIS OF HELICOPTER NORMAL LOAD FACTORS IN MANEUVERS. F. B. Gustafson and Almer D. Crim. August 1953. 29p. diagrs., photos., 2 tabs. (NACA TN 2990)

Flight tests have been conducted in two single-rotor helicopters to determine the load factors due to various maneuvers. A simple theoretical method of estimating for new designs the maximum load factor that can be attained for any given flight condition is also presented, and the results compared with those obtained from the flight tests.

ACCELERATIONS AND PASSENGER HARNESS LOADS MEASURED IN FULL-SCALE LIGHT-AIRPLANE CRASHES. A. Martin Eiband, Scott H. Simpkinson and Dugald O. Black. August 1953. 67p. diagrs., photos. (NACA TN 2991)

Full-scale light-airplane crashes simulating stall-spin accidents were conducted to determine the decelerations to which occupants are exposed and the resulting harness forces encountered in this type of accident. Crashes at impact speeds from 42 to 60 miles per hour were studied. The airplanes used were of the familiar steel-tube, fabric-covered, tandem, two-seat type. In crashes up to an impact speed of 60 miles per hour, crumpling of the forward fuselage structure prevented the maximum deceleration at the rear-seat location from exceeding 26 to 33g. This maximum g value appeared independent of the impact speed. Restraining forces in the seat-belt - shoulder-harness combination reached 5800 pounds. The rear-seat occupant can survive crashes of the type studied at impact speeds up to 60 miles per hour, if body movement is restrained by an adequate seat-belt - shoulder-harness combination, so as to prevent injurious contact with obstacles normally present in the cabin. Inwardly collapsing cabin structure, however, is a potential hazard in the higher-speed crashes.

NACA TN 3000

STUDIES OF THE USE OF FREON-12 AS A WIND-TUNNEL TESTING MEDIUM. Albert E. von Doenhoff, Albert L. Braslow and Milton A. Schwartzberg. August 1953. 57p. diagrs. (NACA TN 3000)

A number of studies relating to the use of Freon-12 as a substitute medium for air in aerodynamic testing have been made. The use of Freon-12 instead of air makes possible large savings in wind-tunnel drive power. Because of the fact that the ratio of specific heats is approximately 1.13 for Freon-12 as compared with 1.4 for air, some differences exist between data obtained in Freon-12 and in air. Methods for predicting aerodynamic characteristics of bodies in air from data obtained in Freon-12, however, have been developed, which provide substantial agreement in all cases for which comparative data are available. The Freon charging and recovery system used for the Langley low-turbulence pressure tunnel is described.

NACA RM E53F19

MEASUREMENT AND ANALYSIS OF TURBULENT FLOW CONTAINING PERIODIC FLOW FLUCTUATIONS. William R. Mickelsen and James C. Laurence. August 1953. 45p. diagrs. (NACA RM E53F19)

Techniques are presented for the measurement of the energy spectrum of flow fluctuations in both axial and lateral flow directions. A simple spectrum analysis is presented by which quantitative distinction may be made between turbulence and the flow disturbances associated with sound waves in ducts. Experimental data are presented which indicate that the energy spectrum of the turbulence is not affected by periodic and random sound disturbances outside the frequency ranges containing the disturbances. Preliminary measurements are presented that illustrate the effect of combustion on the approach-stream velocity-fluctuation spectra in a ram-jet combustor.

NACA RM L53F16

SOME INFORMATION ON THE STRENGTH OF THICK-SKIN WINGS WITH MULTIWEB AND MULTIPOST STABILIZATION. Roger A. Anderson, Richard A. Pride and Aldie E. Johnson, Jr. August 1953. 19p. diagrs., 3 tabs. (NACA RM L53F16)

The preliminary results of strength tests on thick-skin wing structures are described. Some of the factors which have a major influence on the buckling behavior and strength of multiweb and multipost stiffened construction are illustrated by the data presented, and the conditions under which a combination of multiweb and multipost construction may be used are discussed. Also given are the results of bending tests on hollow circular-arc airfoils.

NACA TM 1335

MOTION OF A CYLINDER UNDER THE SURFACE OF A HEAVY FLUID. (Dvizhenie tsilindra pod poverkhnostyu tyazheloi zhidkosti). L. N. Sretensky. August 1953. 36p. (NACA TM 1335. Trans. from Central Aero-Hydrodynamical Institute, Transactions, Rept. 346, 1938, p. 3-27).

General equations are derived for the approximate solution of the flow of a heavy infinite depth about a submerged circular cylinder where the center of the cylinder is submerged 1.5 diameter or greater. Then by replacing the cylinder by a dipole of a certain strength an equation is derived for the wave resistance of a circular cylinder moving in a fluid of finite depth.

Aeronautical Research Council (Gt. Brit.) THEORETICAL CONSIDERATIONS ON FREE CONVECTION IN TUBES. M. J. Lighthill. July 21, 1952. 44p. diagrs. (ARC 15,074; FM 1758)

Methods are developed for predicting the flow and heat transfer due to free convection in heated vertical tubes, closed at the bottom and opening into a reservoir of cool fluid at the top. These include methods of predicting whether the flow is laminar or turbulent, and whether the boundary layer of heated fluid fills or does not fill the tube, or fills it with a stagnant region near the closed end. The theory is extended to apply to a tube closed at both ends, part heated and part cooled. There is some discussion of a mechanical engineering application in which the external force is not gravity but centrifugal.

THE DESIGN OF THIN FINITE WINGS IN INCOMPRESSIBLE FLOW. G. J. Hancock. September 2, 1952. 17p. diagrs. (ARC 15,185; FM 1788)

A method is developed for designing thin finite wings with prescribed lift distributions. Particular attention is given to wings which, at a certain optimum angle of incidence, have zero loading along the whole leading edge. It is suggested that such a wing will have greater range of lift coefficeint for low drag than other wings with the same plan form. On the basis of the linearized theory a formula, relating the wing surface to the pressure distribution over the surface, is deduced which differs from the usual potential relationship by avoiding the difficulty of the nonuniform convergence with respect to the normal distance away from the wing surface singularities. The surface integral which is developed includes a regular singularity and a definite limiting process. Three examples have been worked out in which the condition of smooth flow at the leading edge is satisfied.

Aeronautical Research Council (Gt. Brit.)
ON EDGE TONES AND ASSOCIATED PHENOMENA. Alan Powell. October 7, 1952. 17p. diagr., photos., tab. (ARC 15,333; FM 1809)

The edge-tone phenomena occurring at high jet speeds have been photographed by the Schlieren method and the sound waves produced are clearly visible. They are of opposite phase on each side of the stream, and microphone traverses have shown this to be the case at low speeds also. This observation makes possible an explanation of the mechanism by virtue of the "sensitivity" of the jet, which is particularly susceptible to this form of acoustic disturbance whereby the sound waves give rise to stream disturbances at the jet orifice. Two basic relationships are given, one connecting the relative phases of the motion and the other dealing with the effective efficiencies of each of the component processes.

SOME REMARKS ON THE CHOICE AND PRESENTATION OF FORMULAE FOR TURBULENT SKIN FRICTION IN COMPRESSIBLE FLOW. R. J. Monaghan. May 1953. 13p. (RAE Tech. Note Aero 2246)

A review of the various formulas which have been developed for estimating turbulent skin friction in compressible flow has already been given and is mainly concerned with the theoretical aspects of the problem. The object of the present note is to examine briefly the practical application of the results obtained. It is suggested that there is now sufficient evidence to justify changing the compressibility parameter from Mach number to the ratio (surface temperature)/(local ambient temperature). The merits of various formulas are discussed and some brief remarks are made on the effects of pressure gradients and on the present state of knowledge concerning transition.

THE MEASUREMENT OF TRUE MEAN PRESSURES AND MACH NUMBERS IN OSCILLATORY FLOW. M. V. Nesbitt. March 1953. 37p. diagrs. (NGTE Memo. M. 180)

In this paper, the problem of measuring mean pressures and Mach numbers under regular oscillating flow conditions is considered. Firstly, a parameter is developed which enables the damping orifice and instrument volume to be designed to give any required variation in pressure in the measuring section. Next the relationship between the measured mean pressure and true mean pressure is determined for rectangular, sine, and sawtooth wave forms and finally the relation between true mean Mach numbers and Mach numbers as computed from true mean pressures is determined for rectangular, sine and sawtooth waves traveling up and downstream.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) THE FORWARD TAKE-OFF OF A HELICOPTER. F. O'Hara. June 26, 1953. 21p. diagrs. (AAEE/Res/276)

A theoretical analysis is given of the accelerated motion of a single rotor helicopter for estimation of the forward take-off performance. The motion is considered in stages during which either the disk attitude to the horizontal or the flight speed is constant. Equations are derived for the motion along and normal to the flight path and solutions are given assuming constant mean values for the aerodynamic forces on the rotor and fuselage. The equations of motion for constant disk attitude have a simple solution for motion from rest (and for special initial conditions) giving a straight flight path, and a general solution giving a curved flight path. The performance at constant speed is considered for a general climb away case and also for climb away approaching steady flight conditions with the thrust approximately equal to the aircraft weight. For application of the theory, charts of the various solutions are given covering a representative range of the variables.

N-26335 *

Royal Aircraft Establishment (Gt. Brit.) DESIGN CRITERION FOR FATIGUE OF WINGS. P. B. Walker. May 1953. 16p. diagr., tab. (RAE Structures 146)

Design criteria for wings are postulated from a study of past and present knowledge of aircraft structural fatigue. Earlier criteria are considered first, and are then followed by new criteria that are believed to be more appropriated to modern conditions. The main general conclusions are, first, that design must be based on a fatigue test of critical components and, secondly, that the conditions for this test must be derived from a typical gust case specially devised for fatigue life, followed by suggested adjustments when statistical information is available concerning the particular operational conditions.

NACA Rept. 1091

EFFECT OF ASPECT RATIO ON THE LOW-SPEED LATERAL CONTROL CHARACTERISTICS OF UNTAPERED LOW-ASPECT-RATIO WINGS EQUIPPED WITH FLAP AND WITH RETRACTABLE AILERONS. Jack Fischel, Rodger L. Naeseth, John R. Hagerman and William M. O'Hare. 1952. ii, 47p. diagrs., 3 tabs. (NACA Rept. 1091. Formerly TN 2347; TN 2348)

A low-speed wind-tunnel investigation was made to determine the lateral control characteristics of a series of untapered low-aspect-ratio wings. Sealed flap ailerons of various spans and spanwise locations were investigated on unswept wings of aspect ratios 1.13, 2.13, 4.13, and 6.13; and various projections of 0.60-semispan retractable ailerons were investigated on the unswept wings of aspect ratios 1.13, 2.13, and 4.13 and on a 45° sweptback wing. The retractable ailerons investigated on the unswept wings spanned the outboard stations of each wing; whereas the plain and stepped retractable ailerons investigated on the sweptback wing were located at various spanwise stations. Design charts based on experimental results are presented for estimating the flap aileron effectiveness for low-aspect-ratio, untapered, unswept wings.

NACA TN 2994

COLUMN STRENGTH OF H-SECTIONS AND SQUARE TUBES IN POSTBUCKLING RANGE OF COMPONENT PLATES. P. P. Bijlaard and G. P. Fisher. August 1953. 106p. diagrs., photos., 6 tabs. (NACA TN 2994)

The column buckling stress in the range where the component plates have buckled is calculated by the method of split rigidities. For the elastic range simple formulas are derived which express the column buckling stress in terms of the Euler buckling stress of the column, the plate or local buckling stress, and the local buckling stress for a higher mode of buckling. For the plastic range a Johnson parabola is proposed which in the buckling-stress - slenderness diagram is tangent to the curve for the elastic column buckling stress in the post-buckling range. Also the case of initially crooked columns is considered. Tests were carried out for a considerable range of slenderness ratios on three H-sections and two square tube sections. The experimental ultimate buckling stresses are in excellent agreement with those predicted by the theory.

NEW EXPERIMENTS ON IMPACT-PRESSURE INTERPRETATION IN SUPERSONIC AND SUBSONIC RAREFIED AIR STREAMS. F. S. Sherman. University of California. September 1953. 73p. diagrs., photos., 2 tabs. (NACA TN 2995)

Results are presented of an experimental investigation of impact-pressure interpretation in supersonic and subsonic rarefied air streams at Mach numbers from 0.1 to 0.7 and 1.7 to 3.4 and in the Reynolds number range from 2 to 800. A study of the effects of impact-probe size on the accuracy of pressure measurements indicated that corrections for viscous effects are less than 1 percent for probes in supersonic flows at Reynolds numbers above 200, where the Reynolds number is based on the velocity, density, and viscosity of the free stream, the reference dimension being the outer diameter of the probe. Viscous-effect corrections are presented for interpretation of pressure measurements at lower Reynolds numbers.

NACA TN 2996

APPRAISAL OF HAZARDS TO HUMAN SURVIVAL IN AIRPLANE CRASH FIRES. Gerard J. Pesman. September 1953. 98p. diagrs., photos., 4 tabs. (NACA TN 2996)

The factors which affect the survival of human beings in airplane accidents followed by fire were studied by conducting full-scale crashes of transport- and cargo-type airplanes. Studies of burning airplane hulks supplemented the information obtained from the crash fires. The time interval during which occupants could escape from a burning airplane was determined by using the time histories of cabin temperatures and toxic gas concentrations in conjunction with data that define the environmental conditions which can be tolerated by human beings. Other hazardous factors, such as flying detached airplane parts, explosions, and crushing of the airplane structure, were also studied.

NACA TN 2998

THE EFFECTS OF CAMBER ON THE VARIATION WITH MACH NUMBER OF THE AERODYNAMIC CHARACTERISTICS OF A 10-PERCENT-THICK MODIFIED NACA FOUR-DIGIT-SERIES AIRFOIL SECTION. Albert D. Hemenover. September 1953. 34p. diagrs., tab. (NACA TN 2998)

The effects of camber on the variation with Mach number of the aerodynamic characteristics of a 10-percent-chord-thick modified NACA four-digit-series airfoil section are determined from tests in the Ames 1- by 3-1/2-foot high-speed wind tunnel

at Mach numbers from 0.3 to 0.9 and corresponding Reynolds numbers from 1×10^6 to 2×10^6. Lift, drag, and pitching-moment characteristics of airfoils cambered for design lift coefficients of 0.2 and 0.4 on an NACA a = 0.8 mean line are compared with those of the corresponding uncambered profile.

NACA TN 3001

Studies of four experimental outer-race-riding cage-type bearings with inner-race-guided rollers, a conventional inner-race-riding cage-type bearing, and a conventional outer-race-riding cage-type bearing with outer-race-guided rollers are reported. All cages were made of nodular iron. The experimental bearings operated at lower temperatures and to higher limiting DN values than did the conventional bearings. The conventional inner-race-riding cage-type bearing had the lowest heat dissipation to the oil, but only at the expense of higher operating temperatures. The conventional outer-race-riding cage-type bearing operated at high temperatures at high oil flows and high speeds because of its tendency to trap oil and create churning losses.

NACA TN 3002

EFFECT OF BRONZE AND NODULAR IRON CAGE MATERIALS ON CAGE SLIP AND OTHER PERFORMANCE CHARACTERISTICS OF 75-MILLIMETER-BORE CYLINDRICAL-ROLLER BEARINGS AT DN VALUES TO 2×10^6. William J. Anderson, E. Fred Macks and Zolton N. Nemeth. September 1953. 24p. diagrs., 6 tabs. (NACA TN 3002)

In an investigation of four outer-race-riding cage-type bearings (two with bronze and two with nodular iron cages) heavy wear was found to accompany cage slip. Nodular iron seemed to promote cage slip at DN values in excess of 1.2×10^6; consequently, bearings with bronze cages showed less wear than did bearings with nodular iron cages at very high speeds. There was little difference in performance between the bronze and nodular iron at DN values to 1.2×10^6

NACA TN 3003

INVESTIGATION OF 75-MILLIMETER-BORE DEEP-GROOVE BALL BEARINGS UNDER RADIAL LOAD AT HIGH SPEEDS. II - OIL INLET TEMPERATURE, VISCOSITY, AND GENERALIZED COOLING CORRELATION. Zolton N. Nemeth, E. Fred Macks and William J. Anderson. September 1953. 33p. diagrs., photos., 2 tabs. (NACA TN 3003)

The extent of the effects of oil inlet temperature and viscosity on bearing inner- and outer-race temperatures is shown. In this investigation, 75-millimeter-bore ball bearings were operated at DN values (bore times speed) from 0.3×10^6 to 2.4×10^6, radial loads from 7 to 1113 pounds, and oil flows from 1.6 to 8 pounds per minute. The cooling correlation previously developed for cylindrical-roller-bearing temperatures was extended and applied to ball bearing temperatures and to the power rejected to the oil by the test bearing. It is possible to predict either the inner- or outer-race bearing temperature or the power rejected to the oil from single curves regardless of whether speed, load, oil flow, oil inlet temperature, oil inlet viscosity or any combination of these parameters is varied. Bearing failure due to breakage of the cage occurred at a DN of 2.4×10^6 (32,000 rpm) when the bearing was lubricated with a medium viscosity oil at an oil inlet temperature of 100° F.

NACA TN 3004

THEORETICAL PERFORMANCE CHARACTERISTICS OF SHARP-LIP INLETS AT SUBSONIC SPEEDS. Evan A. Fradenburgh and DeMarquis D. Wyatt. September 1953. 21p. diagrs. (NACA TN 3004)

A method is presented for the estimation of the subsonic-flight-speed characteristics of sharp-lip inlets applicable to supersonic aircraft. The analysis, based on a simple momentum balance consideration, permits the computation of inlet pressure recovery - mass-flow relations and additive-drag coefficients for forward velocities from zero to the speed of sound. Operation of a sharp-lip inlet at velocity ratios less than 1.0 results in an additive drag that is not cancelled by lip suction, while at velocity ratios greater than 1.0, losses in inlet total pressures result. In particular, at the take-off condition, the total pressure and the mass flow for a choked inlet are only 79 percent of the values ideally attainable with a rounded lip.

NACA TN 3006

CORRELATION OF CALCULATION AND FLIGHT STUDIES OF THE EFFECT OF WING FLEXIBILITY ON STRUCTURAL RESPONSE DUE TO GUSTS. John C. Houbolt. August 1953. 14p. diagrs., tab. (NACA TN 3006)

Flight and calculation studies of two twin-engine transports and one four-engine bomber are presented to show how wing bending flexibility influences the structural response due to gusts. It is shown that an analysis approach based upon single-gust encounter reveals the general nature of the flexibility effects and leads to qualitative correlation with flight results. It is shown further, however, that quantitative correlation can be obtained with an approach that considers continuous-turbulence encounter and is based on generalized harmonic analysis. This approach allows for a greater degree of resolution of the flexibility effects and appears to now provide a suitable means for evaluating these effects.

NACA RM A53G09

TESTS OF THE NACA 0010-1.50 40/1.051 AIRFOIL SECTION AT HIGH SUBSONIC MACH NUMBERS. Albert D. Hemenover. September 1953. 18p. diagrs., tab. (NACA RM A53G09)

Aerodynamic characteristics of the NACA 0010-1.50 40/1.051 airfoil section are compared with those for the same basic airfoil section with leading-edge radii of 1.10, 0.70, and 0.27 percent of the chord at Mach numbers from 0.3 to 0.9. The corresponding Reynolds number variation is from 1×10^6 to 2×10^6.

NACA RM E53F29

PRELIMINARY INVESTIGATION OF THE EFFECTS OF CASCADING ON THE OSCILLATING LIFT FORCE OF AN AIRFOIL VIBRATED IN BENDING. Donald F. Johnson and Alexander Mendelson. September 1953. 15p. diagrs., photos. (NACA RM E53F29)

Measurements were made of the oscillatory lift force acting on an airfoil vibrated in bending. Results were obtained for an isolated airfoil and for the same airfoil oscillated in a cascade, at low and high angles of attack. It was found that at high angles of attack and at low values of the reduced frequency, the damping for the isolated airfoil can become negative. The oscillating lift force changes little, for the case considered, by placing this blade in a stationary cascade. It is indicated that for this case the effect of the cascade is generally to increase the damping by a slight amount.

CURRENT NACA REPORTS

NACA Rept. 1073

AN ITERATIVE TRANSFORMATION PROCEDURE FOR NUMERICAL SOLUTION OF FLUTTER AND SIMILAR CHARACTERISTIC-VALUE PROBLEMS. Myron L. Gossard. 1952. ii, 45p. diagrs., 9 tabs. (NACA Rept. 1073. Formerly TN 2346)

The idea of the iterative transformation procedure suggested by H. Wielandt is explained. Application of the procedure to ordinary natural-vibration problems and to flutter problems is shown in numerical examples. Comparisons of computed results with experimental values and with results obtained by other methods of analysis are made.

NACA Rept. 1077

TWO- AND THREE-DIMENSIONAL UNSTEADY LIFT PROBLEMS IN HIGH-SPEED FLIGHT. Harvard Lomax, Max A. Heaslet, Franklyn B. Fuller and Loma Sluder. 1952. ii, 55p. diagrs., 3 tabs. (NACA Rept. 1077. Formerly TN 2403; TN 2387)

The problem of transient lift on two- and three-dimensional wings flying at high speeds is discussed as a boundary-value problem for the classical wave equation. Kirchhoff's formula is applied so that the analysis is reduced, just as in the steady state, to an investigation of sources and doublets. The applications include the evaluation of indicial lift and pitching-moment curves for two-dimensional sinking and pitching wings flying at Mach numbers equal to 0, 0.8, 1.0, 1.2, and 2.0. Results for the sinking case are also given for a Mach number of 0.5. In addition, the indicial functions for supersonic-edged triangular wings in both forward and reversed flow are presented and compared with the two-dimensional values.

NACA Rept. 1080

A THEORETICAL ANALYSIS OF THE EFFECTS OF FUEL MOTION ON AIRPLANE DYNAMICS. Albert A. Schy. 1952. ii, 22p. diagrs., 2 tabs. (NACA Rept. 1080. Formerly TN 2280)

The general equations of motion for an airplane with a number of spherical fuel tanks are derived. These equations are applied to two cases with two fuel tanks located in the plane of symmetry. The calculated motions show that the airplane motion may be greatly changed by considering the motion of the fuel and, in particular, that small-amplitude residual oscillations may result. The same type of analysis may be applied to arbitrarily shaped tanks; therefore, the most general conclusions as to the effects of the fuel motion on airplane dynamics also apply for arbitrarily shaped tanks.

NACA Rept. 1090

METHOD FOR CALCULATING LIFT DISTRIBUTIONS FOR UNSWEPT WINGS WITH FLAPS OR AILERONS BY USE OF NONLINEAR SECTION LIFT DATA. James C. Sivells and Gertrude C. Westrick. 1952. ii, 25p. diagrs., 13 tabs. (NACA Rept. 1090. Formerly TN 2283)

A method is presented for calculating lift distributions for unswept wings with flaps or ailerons using nonlinear section lift data. This method is based upon lifting-line theory and is an extension to the method described in NACA Rep. 865. Simplified computing forms containing detailed examples are given for both symmetrical and asymmetrical lift distributions. A few comparisons of experimental and calculated characteristics are also presented.

NACA Rept. 1101

FLIGHT INVESTIGATION OF A MECHANICAL FEEL DEVICE IN AN IRREVERSIBLE ELEVATOR CONTROL SYSTEM OF A LARGE AIRPLANE. B. Porter Brown, Robert G. Chilton and James B. Whitten. 1952. ii, 14p. diagrs. (NACA Rept. 1101. Formerly TN 2496)

Data are presented showing the flight characteristics of a large airplane having a control-surface booster and mechanical feel device in the elevator-control system. The tests were made with various force gradients provided by the adjustable feel device. The booster was set to operate at a very high boost ratio throughout the tests so that the measured or apparent stick-free stability would be influenced only slightly by the aerodynamic hinge moments. The results show the effect of the feel device on the handling qualities of the test airplane and also the design features which should be incorporated in such feel devices.

NACA Rept. 1105

CHORDWISE AND COMPRESSIBILITY CORRECTIONS TO SLENDER-WING THEORY. Harvard Lomax and Loma Sluder. 1952. ii, 19p. diagrs., 4 tabs. (NACA Rept. 1105. Formerly TN 2295)

Corrections to slender-wing theory are obtained by assuming a spanwise distribution of loading and determining the chordwise variation which satisfies the appropriate integral equation. Such integral equations are set up in terms of the given vertical induced velocity on the center line or, depending on the

type of wing plan form, its average value across the span at a given chord station. The chordwise distribution is then obtained by solving these integral equations. Results are shown for flat-plate, rectangular, and triangular wings.

NACA Rept. 1107

AN EMPIRICALLY DERIVED BASIS FOR CALCULATING THE AREA, RATE, AND DISTRIBUTION OF WATER-DROP IMPINGEMENT ON AIRFOILS. Norman R. Bergrun. 1952. ii, 21p. diagrs., 6 tabs. (NACA Rept. 1107)

An empirically derived basis for predicting the area, rate, and distribution of water-drop impingement on airfoils of arbitrary section is presented. The concepts involved represent an initial step toward the development of a calculation technique which is generally applicable in the design of thermal ice-prevention equipment for airplane wing and tail surfaces. The calculation technique presented is based on results of extensive water-drop trajectory computations for five airfoil cases which consisted of 15-percent-thick airfoils encompassing a moderate lift-coefficient range. The differential equations pertaining to the paths of the drops were solved by a differential analyzer.

NACA Rept. 1109

EXPERIMENTAL INVESTIGATION OF BASE PRESSURE ON BLUNT-TRAILING-EDGE WINGS AT SUPERSONIC VELOCITIES. Dean R. Chapman, William R. Wimbrow and Robert H. Kester. 1952. ii, 19p. diagrs., photos., tab. (NACA Rept. 1109. Formerly TN 2611)

The pressures acting on the base of blunt-trailing-edge airfoils have been measured at Mach numbers of 1.25, 1.5, 2.0, and 3.1 and at Reynolds numbers from 0.2 to 3.8 million. Data are presented for 29 profiles both with laminar and with turbulent boundary layers approaching the trailing edges of the wings. The base pressure is found to be a function primarily of Mach number and the ratio of the boundary layer thickness at the trailing edge to the trailing-edge thickness.

NACA Rept. 1111

AN ANALYSIS OF LAMINAR FREE-CONVECTION FLOW AND HEAT TRANSFER ABOUT A FLAT PLATE PARALLEL TO THE DIRECTION OF THE GENERATING BODY FORCE. Simon Ostrach. APPENDIX B: NUMERICAL SOLUTION OF SIMPLIFIED BOUNDARY-VALUE PROBLEM. Lynn U. Albers. 1953. ii, 17p. diagrs., tab. (NACA Rept. 1111. Formerly TN 2635)

A formal and general analysis of the free-convection flow about a flat plate parallel to the direction of the generating body force is made, and velocity and temperature distributions for Prandtl numbers of 0.01, 0.72, 0.733, 1, 2, 10, 100, 1000, and large Grashof numbers are computed. The distributions for Prandtl number of 0.72 compare favorably with experimental values. It is shown that velocities and Nusselt numbers of the same order of magnitude as those associated with forced-convection flows can be obtained under free-convection conditions. A flow and a heat-transfer parameter are derived from which the important physical quantities can be computed. Reasonable agreement is obtained among values of the heat-transfer parameter obtained from an approximate theoretical development, experiments, and the present development.

NACA TN 2979

EFFECTS OF SYMMETRIC AND ASYMMETRIC THRUST REVERSAL ON THE AERODYNAMIC CHARACTERISTICS OF A MODEL OF A TWIN-ENGINE AIRPLANE. Kenneth W. Goodson and John W. Draper. September 1953. 67p. diagrs., photo., tab. (NACA TN 2979)

An investigation was made to determine the magnitude and degree of changes in static forces and moments caused by variations of symmetric and asymmetric thrust reversal on a twin-engine airplane. The effects of both positive and negative thrust coefficients were investigated on the individual propellers and covered a thrust-coefficient range of 0.167 to -0.150.

NACA TN 2983

LINEARIZED POTENTIAL THEORY OF PROPELLER INDUCTION IN A COMPRESSIBLE FLOW. Robert E. Davidson. September 1953. 47p. diagrs., 5 tabs. (NACA TN 2983)

This paper gives the potential-theory representation of the wave-equation flow about a lifting-line propeller of finite number of blades and arbitrary circulation distribution. From the velocity potential, the compressible inflow velocities at the blade became known. The induced velocities are known also at any point in the flow because the velocity potential is determined for the whole field.

NACA TN 2997

APPLICATION OF SEVERAL METHODS FOR DETERMINING TRANSFER FUNCTIONS AND FREQUENCY RESPONSE OF AIRCRAFT FROM FLIGHT DATA. John M. Eggleston and Charles W. Mathews. September 1953. 74p. diagrs., 2 tabs. (NACA TN 2997)

A study is presented of several methods for determining the transfer functions and frequency response of aircraft from flight tests. Results obtained from experience in the use of these methods are compared as to time required for application, comparative accuracy, and means for facilitating their use. The studies cover three categories of methods: sinusoidal response, Fourier analysis of transients, and curve-fitting analysis of transients. Three general types of aircraft are used to illustrate the application of these methods.

NACA TN 2999

IMPINGEMENT OF DROPLETS IN 90° ELBOWS WITH POTENTIAL FLOW. Paul T. Hacker, Rinaldo J. Brun and Bemrose Boyd. September 1953. 58p. diagrs., 2 tabs. (NACA TN 2999)

Trajectories were determined for droplets in air flowing through 90° elbows especially designed for two-dimensional potential motion with low pressure losses. The elbows were established by selecting as walls of each elbow two streamlines of the flow field produced by a complex potential function that establishes a two-dimensional flow around a 90° bend. An unlimited number of elbows with slightly different shapes can be established by selecting different pairs of streamlines as walls. The elbows produced by the complex potential function selected are suitable for use in aircraft air-intake ducts. The droplet impingement data derived from the trajectories are presented along with equations in such a manner that the collection efficiency, the area, the rate, and the distribution of droplet impingement can be determined for any elbow defined by any pair of streamlines within a portion of the flow field established by the complex potential function. Coordinates for some typical streamlines of the flow field and velocity components for several points along these streamlines are presented in tabular form.

NACA TN 3005

HEAT TRANSFER AND SKIN FRICTION BY AN INTEGRAL METHOD IN THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH A STREAMWISE PRESSURE GRADIENT. Ivan E. Beckwith. September 1953. 55p. diagrs., tab. (NACA TN 3005)

A simplified method has been developed for the calculation of heat transfer and skin friction in the compressible laminar boundary layer with an arbitrary Prandtl number near unity and an arbitrary streamwise pressure gradient and wall temperature distribution. The use of a fifth-degree polynomial for the stagnation enthalpy profile gives results of good accuracy for the case of boundary-layer cooling. The method has been extended to the calculation of heat transfer under conditions of equilibrium dissociation in the boundary layer. By means of a suitable transformation the method is also applied to a body of revolution with a boundary-layer thickness of the order of the body radius.

NACA TN 3007

LIFT AND PITCHING MOMENT AT LOW SPEEDS OF THE NACA 64A010 AIRFOIL SECTION EQUIPPED WITH VARIOUS COMBINATIONS OF A LEADING-EDGE SLAT, LEADING-EDGE FLAP, SPLIT FLAP, AND DOUBLE-SLOTTED FLAP. John A. Kelly and Nora-Lee F. Hayter. September 1953. 45p. diagrs., photos., 2 tabs. (NACA TN 3007)

Results of a two-dimensional wind-tunnel investigation of an NACA 64A010 airfoil equipped with a leading-edge flap, a leading-edge slat, a split flap, and a double-slotted flap are presented. The results include determination of optimum slat positions and effects of varying Reynolds number on the lift and pitching-moment characteristics of the model with the various high-lift devices.

NACA TN 3008

EFFECTS OF FINITE SPAN ON THE SECTION CHARACTERISTICS OF TWO 45° SWEPTBACK WINGS OF ASPECT RATIO 6. Lynn W. Hunton. September 1953. 32p. diagrs. (NACA TN 3008. Formerly RM A52A10)

A study has been made of the finite-span effects on the local loading characteristics of two sweptback wings at low speed with a view toward providing some insight into the usefulness of two-dimensional section data and span-loading theory for determining the section characteristics of a swept wing. The two wings considered were identical in plan form having 45° of sweepback of the quarter-chord line, an aspect ratio of 6, and a taper ratio of 0.5 but differed in twist and in sections, the latter being the NACA 64A010 and NACA 64A810. The analysis is based on comparisons of local pressure distributions and local lift characteristics on the wings with comparable two-dimensional section data, all of which were available at large scale.

NACA TN 3009

VELOCITY POTENTIAL AND AIR FORCES ASSOCIATED WITH A TRIANGULAR WING IN SUPERSONIC FLOW, WITH SUBSONIC LEADING EDGES, AND DEFORMING HARMONICALLY ACCORDING TO A GENERAL QUADRATIC EQUATION. Charles E. Watkins and Julian H. Berman. September 1953. 61p. diagrs., tab. (NACA TN 3009)

The velocity potential for a triangular wing with subsonic leading edges experiencing harmonic deformations in supersonic flow is treated herein. The oscillations considered are such that the amplitude of distortion of the wing can be represented by a general quadratic equation. The velocity potential is derived in the form of a power series in terms of the frequency of oscillation. Although only the first four terms of the series expansion are presented, additional terms may be obtained if desired. The material constitutes an extension of the work given in NACA Report 1099.

NACA TN 3011

COEFFICIENT OF FRICTION AND DAMAGE TO CONTACT AREA DURING THE EARLY STAGES OF FRETTING. I - GLASS, COPPER, OR STEEL AGAINST COPPER. Douglas Godfrey and John M. Bailey. September 1953. 23p. diagrs., photos., 2 tabs. (NACA TN 3011)

Experiments were conducted to measure the coefficient of friction μ and to determine the damage to the contact area during early stages of fretting of copper at a frequency of 5 cycles per minute. Specimen combinations of copper against glass, copper against copper, and copper against steel, as well as various copper oxide films and powder compacts, were used. The results lead to the conclusion that fretting of copper starts with the same mechanical damage that occurs during unidirectional sliding. Fretting of copper against glass, copper against copper, and copper against steel starts with adhesion and metal transfer (galling) with accompanying high μ values (>1.0) the same as those obtained during unidirectional sliding. After the ini-

tial high values of μ, a reduction in μ was observed, associated with reduced plowing and an increasing concentration of debris in and around the contact area. After approximately 100 cycles of fretting, μ reached a constant value (0.5-0.6) approximately the same as that obtained with compacts of either cuprous or cupric oxide. The presence of preformed cuprous or cupric oxide films on copper does not delay the occurrence of fretting but only lowers the initial coefficient of friction.

NACA TN 3012

AN ANALYSIS OF TURBOJET-ENGINE-INLET MATCHING. DeMarquis D. Wyatt. September 1953. 19p. diagrs. (NACA TN 3012)

A method of presenting turbojet-engine air-flow requirements and inlet-system air-flow capacities in identical though independent parametric terms is developed. The application of the air-flow representation technique to the analysis of engine-inlet matching conditions is demonstrated. Several examples are presented to illustrate the application of the method to the explicit determination of inlet geometric variations required to improve the powerplant performance of supersonic airplanes.

NACA TN 3014

CALCULATED SPANWISE LIFT DISTRIBUTIONS AND AERODYNAMIC INFLUENCE COEFFICIENTS FOR UNSWEPT WINGS IN SUBSONIC FLOW. Franklin W. Diederich and Martin Zlotnick. September 1953. 120p. diagrs., 11 tabs. (Tables of F matrices to be used with TN 3014 are published separately) (NACA TN 3014)

Spanwise lift distributions have been calculated for nineteen unswept wings with various aspect ratios and taper ratios and with a variety of angle-of-attack or twist distributions, including flap and aileron deflections, by means of the Weissinger method with eight control points on the semispan. Also calculated were aerodynamic influence coefficients which pertain to a certain definite set of stations along the span, and several methods are presented for calculating aerodynamic influence coefficients for stations other than those stipulated.

NACA TN 3015

AN EXPERIMENTAL INVESTIGATION OF SECONDARY FLOW IN AN ACCELERATING, RECTANGULAR ELBOW WITH 90° OF TURNING. John D. Stanitz, Walter M. Osborn and John Mizisin. October 1953. 60p. diagrs., photos., 2 tabs. (NACA TN 3015)

Secondary flow tests were conducted on an accelerating elbow with 90° of turning designed for prescribed velocities that eliminate boundary-layer separation by avoiding local decelerations along the walls. Secondary flows were investigated for six boundary-layer thicknesses generated on the plane walls of the elbow by spoilers upstream of the elbow inlet. The passage vortex associated with secondary flows appears to be near the suction surface and away from the plane wall of the elbow at the exit and does not have appreciable spanwise motion as it moves downstream from the elbow exit. As the spoiler size increases, the boundary-layer form changes and a rather sudden difference in the secondary flow occurs, perhaps associated with the reduced importance of viscous effects in thick boundary layers. It is suggested that the strength of the secondary vortices is small and that the energy of secondary flows is small.

NACA TN 3016

ANALYSIS OF TURBULENT HEAT TRANSFER AND FLOW IN THE ENTRANCE REGIONS OF SMOOTH PASSAGES. Robert G. Deissler. October 1953. 88p. diagrs. (NACA TN 3016)

A previous analysis for fully developed turbulent heat transfer and flow with variable fluid properties is extended and applied to the entrance regions of smooth tubes and parallel flat plates. Integral heat-transfer and momentum equations are used for calculating the thicknesses of the thermal and flow boundary layers. The effect of variable properties is determined for the case of uniform heat flux, uniform initial temperature distribution, and fully developed velocity distribution. A number of other cases in which the fluid properties are constant are analyzed. The predicted Nusselt numbers for air with a uniform wall temperature and uniform initial temperature and velocity distributions agree closely with experimentally determined values.

NACA TN 3017

AXIAL-LOAD FATIGUE TESTS ON NOTCHED AND UNNOTCHED SHEET SPECIMENS OF 61S-T6 ALUMINUM ALLOY, ANNEALED 347 STAINLESS STEEL, AND HEAT-TREATED 403 STAINLESS STEEL. Herbert F. Hardrath, Charles B. Landers and Elmer C. Utley, Jr. October 1953. 28p. diagrs., 4 tabs. (NACA TN 3017)

Axial-load fatigue tests at a stress ratio of zero were performed on notched and unnotched sheet specimens of 61S-T6 aluminum alloy and 347 and 403 stainless steels. Special emphasis was placed on tests at high stress levels producing failures in small numbers of cycles. It was found that the stress-concentration factors effective in fatigue of notched specimens were somewhat less than the theoretical elastic values at low stresses and were approximately equal to one at the ultimate strength. The mimimum life to failure at stresses near the ultimate strength was drastically reduced with increasing stress-concentration factor.

NACA TN 3019

INVESTIGATION OF THE STATISTICAL NATURE OF THE FATIGUE OF METALS. G. E. Dieter and R. F. Mehl. Carnegie Institute of Technology. September 1953. 25p. diagrs., 5 tabs. (NACA TN 3019)

Results are presented of an investigation of the statistical nature of the fatigue of metals utilizing statistical methods developed previously. The investigation included a study of the fatigue properties and their statistical variation of a plain carbon eutectoid steel heat-treated to coarse pearlitic and spheroidized structures of the same tensile strength and of commercially pure aluminum (2S) and 24S alloy heat-treated to two different structures. Calcula-

tion of data from the literature provided statistics for 75S aluminum alloy for comparison with the data of the present investigation.

NACA RM E53E05

EFFECT OF PRESSURE ON THE SMOKING TENDENCY OF DIFFUSION FLAMES. Rose L. Schalla and Glen E. McDonald. September 1953. 13p. diagrs., 2 tabs. (NACA RM E53E05)

The effect of pressure on smoke formation was investigated by burning nine hydrocarbon fuels as diffusion flames from a modified wick lamp in an enclosed chamber. The maximum relative rate at which each fuel could be burned without smoking was determined over a pressure range of about 1/2 to 4 atmospheres, and up to 12 atmospheres in the case of one fuel. The results indicate that over this pressure range the maximum smoke-free fuel flow was inversely proportional to the pressure. The relative variation in smoking tendency among the different fuel types was approximately constant at all pressures. From an analysis of the data it has been tentatively proposed that the variations in smoke formation with pressure result from changes in the rate of diffusion and mixing of the fuel and air.

NACA RM E53G08

VAPOR PRESSURES OF CONCENTRATED NITRIC ACID SOLUTIONS IN THE COMPOSITION RANGE 83 TO 97 PERCENT NITRIC ACID, 0 TO 6 PERCENT NITROGEN DIOXIDE, 0 TO 15 PERCENT WATER, AND IN THE TEMPERATURE RANGE 20° TO 80° C. A. B. McKeown and Frank E. Belles. September 1953. 22p. diagrs., tab. (NACA RM E53G08)

Total vapor pressures were measured for 28 acid mixtures of the ternary system nitric acid, nitrogen dioxide, and water within the temperature range 20° to 80° C and within the composition range 83 to 97 percent nitric acid, 0 to 6 percent nitrogen dioxide, and 0 to 15 percent water. The ullage of the apparatus used for the measurements was 0.65. Ternary diagrams showing isobars as a function of composition of the system NO_2-H_2O-HNO_3 were constructed from experimental and interpolated data for the temperatures 25°, 40°, and 60° C and are presented herein.

NACA RM L53G24a

MODEL DITCHING INVESTIGATIONS OF THREE AIRPLANES EQUIPPED WITH HYDRO-SKIS. (Revised) Lloyd J. Fisher. September 1953. 8p. photos. (NACA RM L53G24a)

Calm-water tests were made to determine possible arrangements of hydro-ski ditching gear on typical multiengine airplanes. The tests showed that hydro-skis would afford very satisfactory water landings as compared with landings without skis. The best landings were made in a near-level (slightly nose-up) landing attitude although any normal landing attitude was satisfactory. It is possible that critical damage could be eliminated from ditchings by using a hydro-ski landing gear.

Aeronautical Research Council (Gt. Brit.)
THE DISTURBED MOTION OF ARTICULATED BLADES. H. Roberts. October 1949. 77p. diagrs. (ARC 12,688; H. 127)

The general theory of motion for articulated helicopter blades is presented and allowance is made for for: (a) arbitrary motion of the hub, (b) offset blade hinges, (c) inclined flapping hinges, and (d) cambered blades. The method employed is the simple one of giving the hub prescribed horizontal, vertical, and angular velocities, the motion being two-dimensional. It is shown that the flapping stability equation arises when considering disturbed motion or response phenomena. It is also shown that disturbances in the pitching plane lead in general to a lateral tilt of the rotor disk, thereby inducing a coupling between the longitudinal and lateral stability equations.

THE DETERMINATION OF SKIN TEMPERATURES ATTAINED IN HIGH SPEED FLIGHT. F. V. Davies and R. J. Monaghan. 1953. 65p. diagrs., 8 tabs. (ARC CP 123)

This report discussed the factors affecting skin temperatures attained by high-speed missiles and presents some methods of solution. These have been reduced to graphical or tabular form and are set out in order of complexity. Graphical or algebraic solutions may be quickly obtained if steady conditions are assumed, and for some flight cases these are reasonable approximations to corresponding transient solutions. If the temperature time variation is required, then longer numerical integration processes have to be performed. Account may be taken of external radiation and heat loss to the interior if their effects are considered significant.

Aeronautical Research Council (Gt. Brit.)
THE DEFINITIONS OF THE ANGLES OF INCIDENCE AND OF SIDESLIP. C. H. E. Warren. 1953. 11p. diagrs. (ARC CP 124)

The use of large angles of incidence and of sideslip in missile work, and recent changes in wind-tunnel testing techniques, have shown the need for clear and precise definitions of the angles of incidence and of sideslip. The suitability of different definitions for both experimental and theoretical work in both the aircraft and missile field is considered, and it is concluded that, as no single definition is universally acceptable, care should be taken in theoretical and experimental reports to define precisely the angles used.

N-26522*

Aeronautical Research Council (Gt. Brit.)
PRESSURE ERROR MEASUREMENT USING THE FORMATION METHOD. K. C. Levon. 1953. 15p. diagrs. (ARC CP 126)

Measurements of pressure error at altitude have been made by flying several aircraft in formation with a reference aircraft whose airspeed system had previously been calibrated by radar. Tests made show that analysis by comparison of indicated airspeeds (comparison of differences between static and total head pressures) gives more consistent and reliable results than pressure altitude comparison (comparison of direct measurement of static pressure).

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF COMPRESSIBILITY ON THE PERFORMANCE OF A GRIFFITH AEROFOIL. H. H. Pearcey and E. W. E. Rogers. 1953. 30p. diagrs., photos., 4 tabs. (ARC R & M 2511. Formerly ARC 10,096; FM 1017; Perf. 250)

Experiments were made in the 20-inch by 8-inch high-speed tunnel at the NPL on a 9-inch chord, 22 percent thick, symmetrical Griffith section at 0° incidence. Drag was determined by the pitot traverse method. Information on the flow was obtained from the pitot tube traverses, from direct shadow photographs, and from normal pressure measurements. Three Mach numbers of the undisturbed stream were covered, namely 0.4, 0.6, and 0.7. Estimates of the power absorbed by the compressor, ignoring duct losses are made from measurements of the mass of air sucked and the static pressure in the slots. Additional information was obtained on the adverse effect of a large radius of the forward lip of the slot, on the effect at $M_o = 0.4$ of an increase in slot width, and on the choke quantities for the slots.

THE MEASUREMENT OF THE OVERALL DRAG OF AN AIRCRAFT AT HIGH MACH NUMBERS. D. J. Higton, R. H. Plascott and D. A. Clarke. 1953. 22p. diagrs., photo., tab. (ARC R & M 2748; ARC 11,429; ARC 12,237. Formerly RAE Aero 2241; RAE Aero 2309)

This report describes the technique which has been developed to measure the over-all drag of an aircraft at high Mach numbers in both level flight and dives. It shows how improvements have been made both in flight and tunnel technique so that comparisons between full-scale and model tests have now become possible. Flight results from Meteor IV aircraft show close agreement between drag measured in level flight and in dives and later tests compare well with high-speed wind-tunnel measurements on a 1/12th scale model.

THE THEORETICAL PRESSURE DISTRIBUTIONS AROUND SOME CONVENTIONAL TURBINE BLADES IN CASCADE. T. J. Hargest. 1953. 10p. diagrs. (ARC R & M 2765; ARC 13,360. Formerly NGTE R. 67)

By means of Relf's analogy between aerodynamic streamline flow and electric potential flow, the theoretical pressure distributions around a series of conventional turbine blades in cascade have been determined over a range of incidence covered in some previously reported aerodynamic tests. The theoretical pressure distributions and their variation with incidence provide the basis of an explanation of the observed aerodynamic performance.

Aeronautical Research Council (Gt. Brit.)
A CALCULATION OF THE COMPLETE DOWNWASH IN THREE DIMENSIONS DUE TO A RECTANGULAR VORTEX. Doris E. Lehrian. 1953. 45p. diagrs., 15 tabs. (ARC R & M 2771. Formerly ARC 11,786; S & C 2252; Perf. 487; ARC 12,221; S & C 2294; Perf. 537)

A calculation of the complete downwash in three dimensions due to a rectangular vortex, is given for the limited range $Z = \pm 4$. The downwash is computed at selected positions, in planes normal to the plane of the vortex; these planes are spaced at even integral multiples of the semiwidth of the vortex, measured from the line of symmetry. Values are tabulated for Z in the range (0, 4) and a set of graphs is also included for $0 \leqslant Z \leqslant 2$; they are to be used in conjunction with the "Tables of Complete Downwash due to a Rectangular Vortex" (R. & M. 2461).

REVIEW OF PUBLISHED DATA ON THE EFFECT OF ROUGHNESS ON TRANSITION FROM LAMINAR TO TURBULENT FLOW. Hugh L. Dryden. 6p. diagrs. (Reprint from Journal of the Aeronautical Sciences, v. 20, no. 7, July 1953, p. 477-482).

A review is presented of the published data on the effect of roughness, especially single roughness elements, on transition from laminar to turbulent flow, in which an attempt is made to reanalyze and correlate the available information. The paper also discusses available data on the effect of distributed roughness on transition on a flat plate, as well as some of the published data on roughness effects on transition on airfoils.

CURRENT NACA REPORTS

NACA Rept. 1108

EXPERIMENTAL AERODYNAMIC DERIVATIVES OF A SINUSOIDALLY OSCILLATING AIRFOIL IN TWO-DIMENSIONAL FLOW. Robert L. Halfman, Massachusetts Institute of Technology. 1952. ii, 44p. diagrs., photo., 19 tabs. (NACA Rept. 1108. Formerly TN 2465)

Experimental measurements of the aerodynamic reactions on a symmetrical airfoil oscillating harmonically in a two-dimensional flow are presented and analyzed. Harmonic motions include pure pitch and pure translation, for several amplitudes and superimposed on an initial angle of attack, as well as combined pitch and translation. Considerable consistent data for pure pitch were obtained from a search of available reference material, and several definite Reynolds number effects are evident.

NACA Rept. 1120

RELATIVE IMPORTANCE OF VARIOUS SOURCES OF DEFECT-PRODUCING HYDROGEN INTRODUCED INTO STEEL DURING APPLICATION OF VITREOUS COATINGS. Dwight G. Moore, Mary A. Mason and William N. Harrison. 1953. 12p. photos., diagrs., 5 tabs. (NACA Rept. 1120. Formerly TN 2617)

The purpose of this investigation was to study and to determine experimentally the relative importance of various sources of defect-producing hydrogen introduced into steel during the application of vitreous-type ceramic coatings. Under the conditions investigated, the principal source of defect-producing hydrogen was the dissolved water present in the enamel frit of the coating. Acid pickling, milling water, chemically combined water in the clay, and quenching water were all minor sources. Test results indicate that fishscaling, reboil, and possibly primary boil may be eliminated by using a coating prepared with a water-free frit.

NACA TN 2978

AN APPROXIMATE METHOD OF CALCULATING THE DEFORMATIONS OF WINGS HAVING SWEPT, M OR W, Λ, AND SWEPT-TIP PLAN FORMS. George W. Zender and William A. Brooks, Jr. October 1953. 28p. diagrs., photo. (NACA TN 2978)

An approximate method of calculating the deformations of wings of uniform thickness having swept, M or W, Λ, and swept-tip plan forms is presented. The method employs an adjustment to the elementary beam theory to account for the effect of the triangular root portion of a swept wing on the deformation of the outboard section of the wing. It is shown that, for calculating angles of attack due to loading, the unmodified elementary theory alone suffices.

NACA TN 3010

COMPARISON OF EFFECTIVENESS OF CONVECTION-, TRANSPIRATION-, AND FILM-COOLING METHODS WITH AIR AS COOLANT. E. R. G. Eckert and John N. B. Livingood. October 1953. 52p. diagrs. (NACA TN 3010)

Material necessary for a comparison of the cooling requirements of film and transpiration cooling with conventional convection cooling is presented. Both laminar and turbulent flow, with and without radiation, are considered for a flat plate. The superiority of transpiration cooling is clearly shown for both laminar and turbulent flow.

NACA TN 3013

A NOTE ON SECONDARY FLOW IN ROTATING RADIAL CHANNELS. James J. Kramer and John D. Stanitz. October 1953. 33p. diagrs. (NACA TN 3013)

A general vector differential equation for the vorticity component parallel to a streamline is derived for steady, nonviscous and incompressible flow in a rotating system. This equation is then simplified by restricting it to rotating radial channels and by making further simplifying assumptions. This simplified equation is used to solve for the secondary vorticity, the vorticity component parallel to the streamline, in three special cases involving different streamtube geometries; the results are presented in a series of figures. The secondary vorticity is shown to decrease with decreased absolute angular velocity of the fluid, decreased inlet total-pressure gradient, decreased length of relative flow path, and increased relative velocity.

NACA TN 3018

A THEORETICAL STUDY OF THE EFFECT OF FORWARD SPEED ON THE FREE-SPACE SOUND-PRESSURE FIELD AROUND PROPELLERS. I. E. Garrick and C. E. Watkins. October 1953. 39p. diagrs., tab. (NACA TN 3018)

The sound-pressure field due to thrust and torque of a propeller in flight at uniform subsonic speed is analyzed by use of a distribution of acoustic doublets located at the propeller disk. The results can be regarded as an extension of the work for the static

propeller given by Gutin (NACA TM 1195) for the far pressure field and given by Hubbard and Regier (NACA Rep. 996) for the field near the tips of the rotating propeller. The extended formulas are used to calculate the sound field for a specific two-blade propeller operating at constant torque for various forward-speed Mach numbers.

NACA TN 3020

DETERMINATION OF BOUNDARY-LAYER TRANSITION REYNOLDS NUMBERS BY SURFACE-TEMPERATURE MEASUREMENT OF A 10° CONE IN VARIOUS NACA SUPERSONIC WIND TUNNELS. Albert O. Ross. October 1953. 26p. diagrs., tab. (NACA TN 3020)

An investigation was conducted in the Ames and Lewis supersonic tunnels to determine transition Reynolds numbers on a 10° cone at zero angle of attack. Measurements of surface temperature at known increments along the cone were made for the case of negligible heat transfer and negligible wind-tunnel pressure gradients. The trends of transition Reynolds number with stream Reynolds number and with Mach number are not consistent for the various tunnels. The inconsistencies are attributed to effects of free-stream turbulence, flow irregularities introduced by the compressor systems, and other air-stream disturbances.

NACA TN 3021

A METHOD OF DERIVING FREQUENCY-RESPONSE DATA FOR MOTION OF THE CENTER OF GRAVITY FROM DATA MEASURED ON AN AIRCRAFT AT LOCATIONS OTHER THAN THE CENTER OF GRAVITY. John M. Eggleston. October 1953. 25p. diagrs. (NACA TN 3021)

A method is given for deriving time-response and frequency-response data for angle of attack and normal acceleration of the center of gravity of an aircraft when these data are measured at locations on the aircraft other than the center of gravity and when the pitching velocity is not recorded. The method may be applied to aircraft in which limited recording channels and space limitations restrict the number and location of recording instruments. The application of this method is illustrated with data obtained from drop tests of a freely falling model.

NACA TN 3024

MAXIMUM EVAPORATION RATES OF WATER DROPLETS APPROACHING OBSTACLES IN THE ATMOSPHERE UNDER ICING CONDITIONS. Herman H. Lowell. October 1953. 56p. diagrs., 3 tabs. (NACA TN 3024)

Maximum possible evaporation rates of water droplets approaching obstacles in the atmosphere along stagnation lines or moving within intake ducts of airplanes under icing conditions were calculated for a wide variety of ambient conditions, flight Mach numbers, degrees of stagnation of the incident relative air stream, and droplet diameters. Droplet diameter, body size, and flight Mach number effects were found to predominate, whereas wide variation in ambient conditions had little effect on evaporative losses. It was concluded that little or no evaporative loss occurs from droplets approaching small obstacles such as liquid-water-content measurement cylinders, whereas losses may be as high as several percent in the case of larger obstacles such as wings, or 50 percent in the case of ducts at high ram pressure. Losses in ducts in general, however, will usually be about 10 to 20 percent.

NACA TN 3025

AN INVESTIGATION UTILIZING AN ELECTRICAL ANALOGUE OF CYCLIC DE-ICING OF HOLLOW STEEL PROPELLERS WITH INTERNAL ELECTRIC HEATERS. Carr B. Neel, Jr. October 1953. 31p. diagrs., photo., 3 tabs. (NACA TN 3025)

An analytical study, utilizing an electrical analogue, of the heat requirements for cyclic de-icing of hollow steel propellers fitted with two types of internal electric heaters showed the impracticability of using an internal tubular heater, and illustrated the advantages of employing an internal shoe-type heater to distribute the heat more evenly to the blade surface. The importance of minimizing the thermal inertia of the system was demonstrated, and the magnitude of reductions in the total energy requirement made possible through reductions in heating period was indicated.

NACA TN 3031

PRELIMINARY EXPERIMENTAL INVESTIGATION OF LOW-SPEED TURBULENT BOUNDARY LAYERS IN ADVERSE PRESSURE GRADIENTS. Virgil A. Sandborn. October 1953. 37p. diagrs., photos. (NACA TN 3031)

Measurements of velocity profiles and skin friction in subsonic turbulent boundary layers with adverse pressure gradients are presented. The skin friction was measured by using a local heat-transfer instrument and employing a calibrated relation between heat transfer and skin friction. The skin friction in an adverse pressure gradient was found to decrease steadily with distance to a value approaching zero for the region of separation. The measured values of skin friction were related to the form factor and momentum thickness of the measured velocity profiles substantially in accordance with the equation of Ludwieg and Tillmann. Momentum thickness θ and mean velocity-profile-form parameters H computed according to the semiempirical method of Maskell have been compared with the measured quantities. From the agreement it is concluded that the method (which exploits the Ludwieg-Tillman formula for skin friction) gives results, for the flows investigated, well within a range of engineering accuracy for the predictions of profile parameters, local skin friction, and the point of flow separation; required data for the calculation are the profile parameters at a starting point and the pressure distribution.

NACA TN 3033

APPLICATION OF AN ELECTRO-OPTICAL TWO-COLOR PYROMETER TO MEASUREMENT OF FLAME TEMPERATURE FOR LIQUID OXYGEN - HYDROCARBON PROPELLANT COMBINATION. M. F. Heidmann and R. J. Priem. October 1953. 39p. diagrs., photos. (NACA TN 3033)

The development of an electro-optical two-color pyrometer and its application to the measurement of temperature and emissivity in the exhaust gases of an open-tube combustor during normal and oscillatory combustion are described. Temperature variations up to 1000° R and emissivity variations of 10 to 1 were measured; the variations were sporadic and periodic during normal and oscillatory operation, respectively. The results of simultaneous measurements of sound intensity and temperature by the two-color method and by a microwave absorption technique are also presented.

Aeronautical Research Council (Gt. Brit.)
EXPERIMENTS ON CONICAL DIFFUSERS. H. B. Squire. 1953. 18p. diagrs., tab. (ARC R & M 2751; ARC 12,838. Formerly RAE Aero 2216; ARC 13,499; TP 320)

Measurements of the characteristics of conical diffusers of area ratio 4 between entry and exit and of total cone angle 4°, 5°, 6°, 8°, and 10° were made to determine the effect of Reynolds number on efficiency for uniform entry flow. A range of entry Reynolds number between 5×10^4 and 10^6 was covered. The pressure distributions along the walls and the velocity distributions at the end of the conical sections were measured. Further measurements of velocity distribution were made with conical diffusers of area ratio 16 between entry and exit and with pipe flow at the entry, to determine the velocity distributions which finally develop.

SOME NOTES ON IRREVERSIBLE MACHINES. D. Rendel and J. Rudman. May 1953. 27p. diagrs., photo., tab. (RAE Tech. Note Mech. Eng. 144)

A mathematical analysis has been made of the simple type of irreversible machine without lost motion in which the internal frictional forces can be expressed in terms of the external loading. The analysis emphasises that the most efficient type of machine would be one in which, when operating against an opposing load, the input force gradually releases a brake which holds the output load. A model machine of this type, which can theoretically be made over 50-percent efficient, has been tested and found to be usable and irreversible up to an efficiency of 80 percent. A description of this machine and the tests

made on it is given in the appendix which may be read without reference to the main text. Other forms of irreversible machines are more generally surveyed and their probable defects pointed out.

Royal Aircraft Establishment (Gt. Brit.)
ESTIMATION OF THE FATIGUE LIFE OF A TRANSPORT AIRCRAFT. P. B. Walker. July 1953. 9p. (RAE Structures 149)

A simple formula is presented for the safe life of an aircraft under reasonably good operating conditions from the standpoint of wing fatigue. Gusts are treated as the main factor in determination of fatigue life, though other factors are allowed for as being secondary. Before the formula can be used a simple fatigue test is required on critical components, and repeated several times to establish variation of nominally identical specimens. The loading cycle for this test corresponds to a sequence of up and down gusts of 8 ft/sec equivalent velocity. The life obtained is termed the "Standard Life" and corresponds to normal operating conditions on European Air Lines. Reservations in the use of the formula and correction for other operating conditions are discussed in general terms.

LEAKAGE TESTS ON SOLID AND INFLATABLE RUBBER SEALS DESIGNED FOR USE IN WIND TUNNELS. D. I. T. P. Llewelyn-Davies and M. T. Caiger. January 1953. 24p. diagrs., tab. (RAE Tech. Note Aero 2219)

Tests have been made on two types of rubber seals designed for use in a variable pressure wind tunnel. A solid seal was designed which would satisfactorily seal gaps of up to 0.04 inch against pressure differences of $\pm$1 atmosphere from atmospheric pressure and which required a minimum sealing force of 5 lb/inch run of seal. It is essential to keep to a minimum the number of joints in the seal and also it is important that the seal should be a loose fit in its groove. A minimum inflation pressure of 30 lb/sq in. gage was required to ensure satisfactory sealing when an inflatable seal was used to seal gaps of up to 0.128 inch against the same range of pressure differences. When sealing against pressures higher than atmospheric, the performance deteriorated rapidly due to the decrease of the effective seal pressure. Care was necessary to ensure that the seal did not roll out of its groove when the joint surfaces were slid apart.

THE CALCULATION OF BOUNDARY LAYER STABILITY ON A FLAT SURFACE WITH HEAT TRANSFER USING AN INTEGRAL SOLUTION FOR THE MEAN FLOW. Martin Bloom. June 1951. 35p. diagrs., 2 tabs. (Polytechnic Inst. of Brooklyn. PIBAL Rept. 179)

The compressible laminar boundary layer over a flat surface with heat transfer at the surface, a unit Prandtl number, and a linear temperature viscosity relation, is considered. The one-parameter Karman Pohlhausen integral method is applied with a sixth-degree polynomial assumed for the velocity profile. The method is shown to predict accurately the velocity profile slopes and curvatures. It is also shown to give good stability estimates as compared with mathematically exact solutions. The procedure for estimating the minimum critical Reynolds number for instability is modified to extend its applicability somewhat for extreme amounts of heat transfer and high Mach numbers.

CURRENT NACA REPORTS

NACA Rept. 1094

AN EXPERIMENTAL INVESTIGATION OF TRANSONIC FLOW PAST TWO-DIMENSIONAL WEDGE AND CIRCULAR-ARC SECTIONS USING A MACH-ZEHNDER INTERFEROMETER. Arthur Earl Bryson, Jr., California Institute of Technology. 1952. ii, 33p. diagrs., photos. (NACA Rept. 1094. Formerly TN 2560)

Interferometer measurements are given of the flow fields near two-dimensional wedge and circular-arc sections at zero angle of attack. Pressure distributions and drag coefficients as functions of Mach number were obtained and the wedge data are compared with theory. It is shown that the local Mach number at any point on the surface of a finite three dimensional body or an unswept two-dimensional body, moving through an infinite fluid, has a stationary value at Mach number 1 and, in fact, remains nearly constant for a range of speeds below and above Mach number 1. On the basis of this concept and the experimental data, pressure distributions and drag coefficients for the wedge and circular-arc sections are presented throughout the entire transonic range of velocities.

NACA Rept. 1097

STRESSES IN A TWO-BAY NONCIRCULAR CYLINDER UNDER TRANSVERSE LOADS. George E. Griffith. 1952. ii, 12p. diagrs., 3 tabs. (NACA Rept. 1097. Formerly TN 2512)

A method, taking into account the effects of flexibility and based on a general eighth-order differential equation, is presented for finding the stresses in a two-bay, noncircular cylinder the cross section of which can be composed of circular arcs. Numerical examples are given for two cases of ring flexibility for a cylinder of doubly symmetrical (essentially elliptic) cross section, subjected to concentrated radial, moment, and tangential loads. The results parallel those already obtained for shells with circular rings.

NACA Rept. 1112

HYDROCARBON AND NONHYDROCARBON DERIVATIVES OF CYCLOPROPANE. Vernon A. Slabey, Paul H. Wise and Louis C. Gibbons. 1953. ii, 18p. diagrs., 4 tabs. (NACA Rept. 1112)

The methods used to prepare and purify 19 hydrocarbon derivatives of cyclopropane are discussed. Of these hydrocarbons, 13 were synthesized for the first time. In addition to the hydrocarbons, six cyclopropylcarbinols, five alkyl cyclopropyl ketones, three cyclopropyl chlorides, and one cyclopropanedicarboxylate were prepared as synthesis intermediates. The melting points, boiling points, refractive indices, densities, and, in some instances, heats of combustion of both the hydrocarbon and nonhydrocarbon derivatives of cyclopropane were determined. These data and the infrared spectrum of each of the 34 cyclopropane compounds are presented herein. The infrared absorption bands characteristic of the cyclopropyl ring are discussed, and some observations are made on the contribution of the cyclopropyl ring to the molecular refractions of cyclopropane compounds.

NACA Rept. 1113

SPECTRUM OF TURBULENCE IN A CONTRACTING STREAM. H. S. Ribner and M. Tucker. 1953. ii, 17p. diagrs., tab. (NACA Rept. 1113. Formerly TN 2606)

Spectrum concepts are employed to study the selective effect of a stream contraction on longitudinal and lateral turbulent velocity fluctuations. By consideration of the effect of stream contraction on a single plane wave, the effect on spectrum and correlation tensors of the turbulence is determined. Weak turbulence and an inviscid fluid are postulated; compressibility of mean flow only is taken into account. For axisymmetric contraction and isotropic initial turbulence, explicit results are obtained. The one dimensional longitudinal spectrum is found to be markedly distorted. The selective effect of contraction on longitudinal and lateral components of turbulence is found to be given uniquely, regardless of details of the isotropic spectrum; comparison with experiment is made.

NACA TN 3022

METHOD FOR STUDYING HELICOPTER LONGITUDINAL MANEUVER STABILITY. Kenneth B. Amer. October 1953. ii, 52p. diagrs., photos., 2 tabs. (NACA TN 3022)

A theoretical analysis of helicopter maneuver stability is made and the results are compared with experimental results for both a single- and a tandem-rotor helicopter. Techniques are described for measuring in flight the significant stability derivatives for use with the theory to aid in design studies of means for achieving marginal maneuver stability for a prototype helicopter.

trostatic sparks, generated when detached airplane parts fly through clouds of dust and fuel mist, was investigated. Within the limits of variables studied, the rates with which airplane wreckage collected a charge were directly proportional to the rate that clay dust or fuel mist was intercepted. Maximum rates of experimental electrification were used to relate energy accumulation to wreckage sizes and trajectories and to estimate minimum hazardous wreckage sizes and trajectories. Comparison of sizes and trajectories of wreckage shown in motion pictures of airplane crashes with these estimated sizes and trajectories indicated that the hazard is small. Of the remedial measures considered, polyethylene coatings were found to offer promise of protection against electrostatic spark ignition.

NACA TN 3027

INFLUENCE OF ROTOR-ENGINE TORSIONAL OSCILLATION ON CONTROL OF GAS-TURBINE ENGINE GEARED TO HELICOPTER ROTORS. John C. Sanders. October 1953. 40p. diagrs., photos., 2 tabs. (NACA TN 3027)

Equations were developed for the torsional motion of a gas-turbine engine geared to a helicopter rotor in which the rotor blades were hinged to the rotor shaft. The rotor system was simplified to yield simple third-order equations that can be used in the analysis of engine control. Comparison of the system response calculated from these equations with the experimentally observed frequency response of a rotor from a 2500-pound helicopter showed satisfactory agreement. Calculations showed that the torsional motion arising from the hinged construction of the blades contributed to instability of the engine-speed and engine-torque controls. Trends in stability and response of controls with increasing weight of helicopters were investigated.

NACA TN 3028

THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER AND SMALL PRESSURE GRADIENT. George M. Low. APPENDIX B. NUMERICAL SOLUTION OF DIFFERENTIAL EQUATIONS. Lynn U. Albers. October 1953. 68p. diagrs., 7 tabs. (NACA TN 3028)

A perturbation method for the calculation of velocity and temperature profiles, skin-friction and heat-transfer characteristics for two-dimensional compressible laminar boundary layers with heat transfer and small arbitrary gradient is presented. The permissible pressure gradients include those of a form and magnitude usually encountered over slender aerodynamic shapes in supersonic flight. The combined effects of heat transfer and pressure gradient on boundary-layer characteristics are demonstrated by applying the results of the analysis to two representative wings.

NACA TN 3032

AN ANALYTICAL STUDY OF THE EFFECT OF AIRPLANE WAKE ON THE LATERAL DISPERSION OF AERIAL SPRAYS. Wilmer H. Reed, III. October 1953. 46p. diagrs., 3 tabs. (NACA TN 3032)

An analysis is made to determine the trajectories and deposit of aerial spray droplets which are issued into the air disturbances generated by an agricultural airplane. Various nozzle arrangements and droplet-size spectra are considered with a view to improving the uniformity and effective width of the deposit.

NACA TN 3034

GRAPHICAL SOLUTION OF SOME AUTOMATIC-CONTROL PROBLEMS INVOLVING SATURATION EFFECTS WITH APPLICATION TO YAW DAMPERS FOR AIRCRAFT. William H. Phillips. October 1953. 41p. diagrs. (NACA TN 3034)

A graphical method is presented for determining the motion of a freely oscillating system of one degree of freedom stabilized by a controlling device which applies control force in proportion to the displacement of the system, to its rate of change of displacement, or both. The controlling member is assumed to have limitations on its maximum deflection and on its maximum rate of movement. Several examples concerned with the application of yaw dampers to aircraft are presented to illustrate the method, and some conclusions regarding the variation of the stability of the motion with amplitude are obtained.

NACA TN 3035

A PRELIMINARY STUDY OF THE PROBLEM OF DESIGNING HIGH-SPEED AIRPLANES WITH SATISFACTORY INHERENT DAMPING OF THE DUTCH ROLL OSCILLATION. John P. Campbell and Marion O. McKinney, Jr. October 1953. 40p. diagrs., 4 tabs. (NACA TN 3035)

This paper presents some preliminary results of a theoretical investigation to determine what design features appear most important in designing modern high-performance airplanes to have the greatest possible inherent stability of the Dutch roll oscillation in order that the need for artificial stabilizing devices can be minimized. These preliminary results cover the case of fighter airplanes at subsonic speeds.

NACA TN 3036

THE FLOW ABOUT A SECTION OF A FINITE-ASPECT-RATIO NACA 0015 AIRFOIL ON A TRANSONIC BUMP. Jack A. Mellenthin. October 1953. 30p. diagrs., photos., tab. (NACA TN 3036)

Pressure distributions were measured at one spanwise station on a semispan rectangular wing model having an NACA 0015 airfoil section and a moderate aspect ratio. The tests were conducted on a transonic bump at Mach numbers from 0.4 to 1.06. Pressure-distribution plots were integrated to obtain the section lift, drag, and pitching-moment coefficients. At a fixed angle, a region developed over the airfoil surface wherein the local Mach number remained nearly constant as the free-stream Mach number was increased above the critical value. This region covered essentially the whole chord of the airfoil at free-stream Mach numbers near unity.

COUNTING METHODS AND EQUIPMENT FOR MEAN-VALUE MEASUREMENTS IN TURBULENCE RESEARCH. H. W. Liepmann and M. S. Robinson, California Institute of Technology. October 1953. 49p. diagrs., photos. (NACA TN 3037)

Methods of measuring the probability distributions and mean values of random functions as encountered in turbulence research were studied. Applications to the measurement of probability distributions of the axial velocity fluctuation u(t) and its derivative du/dt in isotropic turbulence are shown. The assumption of independent probabilities of u(t) and du/dt was investigated and the results indicate that the assumption is satisfied within a few percent and that there is no evidence that the systematic difference between the microscale of turbulence measured from zero counts and measured independently can be traced entirely to the statistical dependence of u and du/dt. The chronological development of apparatus is described, concluding with the 10-channel statistical analyzer.

NACA TN 3042

HIGH-FREQUENCY PRESSURE INDICATORS FOR AERODYNAMIC PROBLEMS. Y. T. Li, Massachusetts Institute of Technology. November 1953. 52p. diagrs., photos., 4 tabs. (NACA TN 3042)

Three different types of pressure indicators are discussed. Each of these indicators has a unique feature, but all are designed with an attempt to combine both high-frequency response and high resolving power into one instrument. Of the mechanical-electrical-transducer type of pressure indicator, the wire strain gage leads in simplicity. The capacitance type is more versatile because it permits the use of very high frequency carrier systems and thereby cuts down the effective interference in the electronic system. The system utilizing the stretching of a barium-titanate disk produces large signals and results in compact design, but it can only be used for dynamic measurements when temperature variations are slight. Five different types of pressure receivers were tested. The flat-diaphragm type leads the others in simplicity, the spherical-diaphragm type exceeds in dynamic performance, and the catenary-diaphragm type is the one least affected by temperature change.

NACA TN 3045

ANALOGY BETWEEN MASS AND HEAT TRANSFER WITH TURBULENT FLOW. Edmund E. Callaghan. October 1953. 19p. diagrs. (NACA TN 3045)

An analysis of combined heat and mass transfer from a flat plate has been made in terms of Prandtl's simplified physical concept of the turbulent boundary layer. The results of the analysis show that for conditions of reasonably small heat and mass transfer, the ratio of the mass- and heat-transfer coefficients is dependent on the Reynolds number of the boundary layer, the Prandtl number of the medium of diffusion, and the Schmidt number of the diffusing fluid in the medium of diffusion. For the particular case of water evaporating into air, the ratio of mass-transfer coefficient to heat-transfer coefficient is found to be slightly greater than unity.

NACA TM 1360

CONCERNING THE FLOW ABOUT RING-SHAPED COWLINGS. PART XII. TWO NEW CLASSES OF CIRCULAR COWLS. (Uber die Stromung an ringförmigen Verkleidungen. XII Mitteilung: Zwei neue Klassen von Ringhauben). Dietrich Küchemann and Johanna Weber. October 1953. 72p. diagrs., 3 tabs. (NACA TM 1360. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin. UM 3111)

For application in practice for annular radiator fairings and similar arrangements, two new classes of circular cowls are developed by theoretical method, and investigated in a systematic test series regarding their behavior under various working conditions.

NACA RM E53G03

EFFECTIVE THERMAL CONDUCTIVITIES OF MAGNESIUM OXIDE, STAINLESS STEEL, AND URANIUM OXIDE POWDERS IN VARIOUS GASES. C. S. Eian and R. G. Deissler. October 1953. 18p. diagrs., photos., tab. (NACA RM E53G03)

As a part of a general investigation of the effective thermal conductivities of powders, tests were conducted to determine the conductivity of magnesium oxide, stainless steel, and uranium oxide powders in various gases at temperatures between 120° and 1455° F. Fair agreement was obtained between conductivities calculated from experimental data for fine magnesium oxide and stainless steel powders and those calculated from a simplified analysis from a previous investigation, although the experimental values are somewhat higher. Runs were also made to determine the effect of gas pressure on effective thermal conductivity.

NACA RM E53H31

MINIMUM SPARK-IGNITION ENERGIES OF 12 PURE FUELS AT ATMOSPHERIC AND REDUCED PRESSURE. Allen J. Metzler. October 1953. 28p. diagrs., 5 tabs. (NACA RM E53H31)

Minimum spark-ignition energies for 12 pure fuels were measured at reduced pressure, and the data obtained were extrapolated to 1 atmosphere. The fuels investigated included normal and cycloparaffins, olefins, carbon disulfide, and oxygenated compounds such as an alcohol, ether, propylene oxide, and tetrahydropyran; these fuels were ignited at reduced pressures by capacitance sparks of controlled duration. The minimum ignition energies obtained are related to the pressure, the quenching distance, and the maximum fundamental flame velocity of the fuel-air mixture. Also, the experimental data obtained are applied to two correlations of spark-ignition energies to check the data of this investigation with that of others.

NACA RM L53I18a

FACTORS AFFECTING TRANSITION AT SUPERSONIC SPEEDS. K. R. Czarnecki and Archibald R. Sinclair. November 1953. 13p. diagrs. (NACA RM L53I18a)

The paper surveys the available material and summarizes what is known to date about boundary-layer transition at supersonic speeds. Variables studied include Mach number, Reynolds number, pressure gradients, heat transfer, surface roughness, and

angle of attack. The discussion is limited to bodies of revolution because similar reliable data for wings is lacking.

Aeronautical Research Council (Gt. Brit.)
WING-FUSELAGE FLUTTER OF LARGE AEROPLANES. W. P. Jones. 1953. 46p. diagrs., 7 tabs. (ARC R & M 2656. Formerly ARC 11,024; 0.688)

A general theoretical method is described which takes into account a large number of degrees of freedom and is based on the design data for the airplane. The problem specifically investigated is the symmetrical flutter of a particular aircraft. Twelve degrees of freedom are assumed to cover pitching and translational motion of the whole airplane, flexure and torsion of the wings, and fuselage vertical bending. The tailplane is regarded as rigid. In the case considered, estimates indicate that the lowest critical speed is well above the maximum design speed of the airplane. The influence of the additional degrees of freedom associated with movements of the control surfaces is not considered.

CALCULATIONS OF THE PRESSURE DISTRIBUTIONS AND BOUNDARY LAYER DEVELOPMENT ON A BODY OF REVOLUTION WITH VARIOUS PARABOLIC AFTERBODIES AT SUPERSONIC SPEEDS. L. E. Fraenkel. February 1953. 56p. diagrs., 4 tabs. (RAE Aero 2482)

Detailed calculations are made of the flow over a series of bodies at Mach numbers of 1.2, 1.4, and 1.6 and Reynolds numbers of 48 to 72 millions. The bodies consist of a basic forebody and parallel portion to which are added truncated parabolic afterbodies of three different thickness ratios. Calculation of the flow over the bodies is done by the method of characteristics. The method of Squire and Young is used to calculate the boundary layer properties. Calculation of the pressure distribution on the "modified" afterbodies is by Ferri's method of linearized characteristics.

THE SOLUTION OF LIFTING-PLANE PROBLEMS BY VORTEX-LATTICE THEORY. V. M. Falkner. 1953. 30p. diagrs., 46 tabs. (ARC R & M 2591. Formerly ARC 10,895; S & C 2153; Perf. 354)

The report describes in detail the methods by which the principles of vortex-lattice theory, introduced in a previous report R & M 1910, are applied to the calculation of the aerodynamic loading of wings by lifting plane theory. The scope of the paper is limited to the application of these principles to symmetrical incidence solutions and symmetrical and antisymmetrical wing twist solutions, for which standard solutions can be treated by comparatively simple loading functions. The effect of discontinuity of direction of leading or trailing edge cannot be avoided even in the simplest solutions, and it has been found necessary to include an investigation of this problem in order to cover the prescribed usage of the method. Special standard functions tabulated in another report are used to allow for the rounding off effects due to change of direction of leading or trailing edge. The general problem of discontinuities is under investigation and will be dealt with in a later report. A comprehensive set of solutions for a delta wing is included in the report in order to show the convergence

N-26843*

of and relation between solutions of varying complexity, and to indicate which solution should be used in order to satisfy the accuracy prescribed for any given problem. The case of the delta wing is not completely general, and the exposition in respect to induced drag and yawing moment will be completed in a later report.

THE EFFECT OF SPANWISE RIB-BOOM STIFFNESS ON THE STRESS DISTRIBUTION NEAR A WING CUT-OUT. E. H. Mansfield. 1952. 21p. diagrs. (ARC R & M 2663; ARC 11,291. Formerly RAE Structures 13)

A theoretical investigation is made into the effect of spanwise rib-boom stiffness on the stress distribution at a cut-out in the interspar skin of a stressed skin wing in bending. Both shear and bending stiffness of the rib-boom are taken into account, and attention is concentrated on the case in which the rib-boom is built-in to the spar flanges. Curves are included which determine, for any particular case, the magnitude of the peak shear stress adjacent to the flange, the approximate spanwise variation of this shear stress, the proportion of load transferred by the rib-boom to the skin and stringers, and the bending moment in the rib-boom at its points of attachment to the spar flanges. By suitable design of the rib-boom, it is possible to lower the shear stresses adjacent to the flange with little or no increase in structure weight.

WIND-TUNNEL TESTS OF THE STALLING PROPERTIES OF AN 8 PER CENT THICK SYMMETRICAL SECTION WITH NOSE SUCTION THROUGH A POROUS SURFACE. R. C. Pankhurst, W. G. Raymer and A. N. Devereux. 1953. 14p. diagrs., tab. (ARC R & M 2666. Formerly ARC 11,496; Perf. 441; FM 1247)

The stalling properties of an 8-percent-thick symmetrical airfoil with large leading-edge radius of curvature and continuous (distributed) suction over the nose have been tested in the 4-foot No. 2 wind tunnel of the National Physical Laboratory. It was found that suction postponed the stall to higher angles of incidence by suppressing separation at the leading edge. The suction also produced beneficial effects in delaying transition. Moreover, it prevented the development of boundary-layer turbulence behind a single excresence or spanwise corrugation, provided the suction was applied over a sufficient chordwise extent of the airfoil surface. The quantity requirements are remarkably small. For example, even at the low Reynolds number of 0.3×10^6 a quantity coefficient $C_Q(Q/Uc)$ of only 0.0036 is sufficient to increase the lift coefficient at 15° increase by 0.6 (from 0.7 to 1.3), and it is to be expected that C_Q will become even less as the Reynolds number is increased. It is not yet possible to estimate the probable power requirements, because the potentialities of the best methods of porous construction are not known.

THE DETERMINATION OF THE NATURAL FREQUENCIES OF A FULL-SCALE AIRFRAME-ENGINE SYSTEM BY THE ADMITTANCE METHOD. J. R. Forshaw and F. T. Mountford. 1953. 24p. diagrs., 3 tabs. (ARC R & M 2667; ARC 11,826. Formerly RAE Tech. Note Structures 20)

The development of the method of the measurement of admittances and the solution of the frequency equation for a complex full-scale airframe-engine system is given, dividing the dynamical system at the attachment of the engine to the airframe, and using a force system of equal and opposite bending moments and shearing forces. The values of the resonance frequencies obtained from the graphical solution of the frequency equation and from the resonance test are compared and found to be in good agreement. The method is applicable to the matching of an engine to an airframe by adjusting the flexibility of the mounting units.

HIGH-SPEED TUNNEL TESTS OF A 5 PER CENT. CHORD DIVE-RECOVERY FLAP ON A NACA 0015 AEROFOIL. D. A. Clarke. 1953. 19p. diagrs., 9 tabs. (ARC R & M 2689; ARC 11,743. Formerly RAE Aero 2269)

Pressure plotting tests were made in the Royal Aircraft Establishment high-speed tunnel on a parallel wooden NACA 0015 wing with dive-recovery flap. The Mach number was varied between 0.30 and 0.80, and the Reynolds number was kept constant at 1.4×10^6. All combinations of the following were tested: flap position 0.2c, 0.3c, 0.4c; flap angle 20°, 40°; incidence 0°, 4°. The flap-chord/wing-chord ratio was 0.05. The report presents a general picture of the action of a dive-recovery flap on a wing. The data are, however, too limited to permit the formulation of general design recommendations.

THE ROYAL AIRCRAFT ESTABLISHMENT 4 FT x 3 FT EXPERIMENTAL LOW TURBULENCE WIND TUNNEL. PART I - GENERAL FLOW CHARACTERISTICS. H. B. Squire and K. G. Winter. 1953. 28p. diagrs., photos., 4 tabs. (ARC R & M 2690; ARC 10,695; ARC 11,410. Formerly RAE Aero 2182; RAE Tech. Note Aero 1937)

The 4- by 3-foot wind tunnel was erected as a model of larger tunnels to investigate unconventional design features directed towards obtaining a high standard of flow. Diffusers of 5° cone angle are used, except for the rapid expansion through three wire-gauze screens up to the maximum section. The contraction ratio is 31.2:1 and nine screens are fitted in the maximum section. A speed control is used operating independently of the fan by means of a bypass duct. The velocity distribution across the working-section is constant to $\pm 1/4$ percent. The standard deviation of the velocity with time measured over a period of 50 sec is 0.03 percent. The flow in the diffusers shows no tendency to separate and the velocity distribution approaching the first screen is very satis-

factory. The installation of cascades with gap/chord ratio of 1/4 gives uniform outlet flow without appreciseparation in the rapid expansion of the bulge, but the flow in the contraction cone is not satisfactory. A longer contraction would have been advantageous. The power factor has been measured as 0.27 with all screens fitted but could be imporved slightly if all the leaks were sealed. The speed control is satisfactory in operation.

Aeronautical Research Council (Gt. Brit.)
AN INVESTIGATION OF THE USE OF AN AUXILIARY SLOT TO RE-ESTABLISH LAMINAR FLOW ON LOW-DRAG AEROFOILS. R. W. Cumming, N. Gregory and W. S. Walker. 1953. 14p. diagrs., photos., tab. (ARC R & M 2742. Formerly ARC 13,003; Perf. 645; FM 1424)

The use of an auxiliary slot on a laminar-flow airfoil has been investigated to check whether laminar flow can be reestablished by suction at the rear of the region of deposited dirt, flies, etc. Results indicate that in the absence of unfavorable pressure gradients, it is possible to reestablish a laminar boundary layer by removing a little more than the whole turbulent layer reaching the slot, and preliminary estimates suggest that with efficient ducting it should be possible to achieve a reduction in over-all effective drag coefficient by this means.

THE TOEPLER SCHLIEREN APPARATUS. D. W. Holder and R. J. North. 1953. 13p. diagrs., photos., 3 tabs. (ARC R & M 2780. Formerly ARC 13,068; FM 1433)

For wind-tunnel observations it is usually necessary that a Toepler schlieren apparatus shall have roughly uniform sensitivity to density gradients within a certain range determined by the nature of the flow. It is also desirable that the illumination in the image of the flow shall be as high as possible if visual observations are to be made under the best conditions and if photographs are to be taken with very short exposures. Methods for satisfying these two requirements are discussed and experimental results are included to illustrate their importance.

LOW SPEED WIND TUNNEL MEASUREMENTS OF THE LIFT ON A 45° SWEPT BACK HALF WING AND CYLINDRICAL BODY. J. A. Lawford. July 1953. 40p. diagrs., 12 tabs. (RAE Tech. Note Aero 2243)

Measurements have been made of the lift, drag, and pitching moment on a 45° sweptback half wing mounted on a cylindrical body. Four wing aspect ratios between 0.5 and 1.5 and two body diameters have been tested. For the larger body the lift due to the wing has been analyzed by pressure plotting into contributions due to lift on the wing and to the lift induced by the wing on the body. The measured lift slopes are compared with values calculated by the method of J. Weber (R.A.E. Report No. Aero 2467). The calculation overestimates the lift slope of the wing-body combination by approximately 10 percent. The tests are part of an investigation to establish a method of estimating the lift slope of this configuration, which occurs when a swept fin is carried on a body of circular section (for example, a jetpipe) and when a single store is carried on a wing tip.

INVESTIGATION OF THE INSTABILITY OF A MOVING LIQUID FILM. H. B. Squire. January 25, 1952. 10p. photos., diagrs., tab. (ARC 14,586; CF 213)

The stability of a thin layer of liquid moving in still air is studied theoretically with the object of throwing light on the break-up of films during atomization. It is found that instability occurs if $W = T/\rho_1 U^2 h < 1$ and that the wave length for maximum growth factor, for $W \ll 1$, is $\lambda = 4\pi T/\rho_2 U^2$ where ρ_1 is the liquid density, ρ_2 is the air density, U is the film velocity, 2h is the film thickness, and T is the surface tension of the liquid. Comparison with experimental data shows fair agreement with the observed wave lengths.

A TECHNIQUE FOR STUDYING THE BEHAVIOUR OF CINE CAMERA MECHANISMS UNDER DYNAMIC CONDITIONS. G. L. Davies. July 1953. 10p. diagrs., photos. (RAE Tech. Note GW 261)

In the design of high-speed cine camera mechanisms, it is not always possible to predict the behavior of the film under dynamic conditions. A simple technique has been developed for measuring running speed, register, film acceleration, shutter timing, and other parameters. The camera under test has its normal shutter replaced by a "negative" shutter, and it is then used to photograph a cathode ray oscilloscope which has a linear saw tooth wave form applied to its X deflection plates. The wave shape of the resulting traces on the film can easily be interpreted to give the required information.

UNPUBLISHED PAPERS

THE MODERN DEVELOPMENT OF THE THEORY OF PROPELLERS. (Le developpement moderne de la theorie de l'helice). Raymond Siestrunck. September 1953. ii, 137p. diagrs. (Trans. from Institut de Mecanique de la Faculte des Sciences de Paris, 1947)

The empirical basis of propeller vortex theory is examined; theories already known are arranged and summarized. The general form of the vortex surfaces with respect to the propeller is specified and evaluation of the field of velocities induced by these vortices is undertaken. The idea is given that the functioning of the propeller depends on the state of the velocities of the surrounding fluid. The problem of determining the distribution of the circulations which induce the velocities along a blade is studied in detail as are the problems of its adaptations for practical use.

THE LANGLEY ANNULAR TRANSONIC TUNNEL. Louis W. Habel, James H. Henderson and Mason F. Miller. 1952. ii, 10p. diagrs., photos. (NACA Rept. 1106. Formerly RM L8A23; RM L50E18)

The development of the Langley annular transonic tunnel, a facility in which test Mach numbers from 0.6 to slightly over 1.0 are achieved by rotating the test model in an annular passage between two concentric cylinders, is described. Data obtained for two-dimensional airfoil models in the Langley annular transonic tunnel at subsonic and sonic speeds are shown to be in reasonable agreement with experimental data from other sources and with theory when comparisons are made for nonlifting conditions or for equal normal-force coefficients rather than for equal angles of attack. The trends of pressure distributions obtained from measurements in the Langley annular transonic tunnel are consistent with distributions calculated for Prandtl-Meyer flow.

NACA Rept. 1110

SOME FEATURES OF ARTIFICIALLY THICKENED FULLY DEVELOPED TURBULENT BOUNDARY LAYERS WITH ZERO PRESSURE GRADIENT. P. S. Klebanoff and Z. W. Diehl, National Bureau of Standards. 1952. 27p. diagrs., photos. (NACA Rept. 1110. Formerly TN 2475)

Results are presented of tests to determine the feasibility of artifically thickening a turbulent boundary layer on a flat plate. It is shown that it is possible to do substantial thickening and obtain a fully developed turbulent boundary layer which is free from any distortions introduced by the thickening process. Measurements of mean velocity, spectrum of u-fluctuation, and intensity of u-fluctuation are presented. Some features of the fully developed turbulent boundary layer with zero pressure gradient are discussed. The mean flow in the boundary layer is compared with the logarithmic laws of mean-velocity distribution derived for pipes and channels, and the existing theories dealing with the shape of the spectrum in isotropic turbulence are applied to the spectrum measured in the outer portion of the boundary layer.

LOW-SPEED DRAG OF CYLINDERS OF VARIOUS SHAPES. Noel K. Delany and Norman E. Sorensen. November 1953. 22p. diagrs., photos., tab. (NACA TN 3038)

An investigation has been conducted to find the approximate variation of the drag coefficient with Reynolds number of cylinders. Data were obtained for circular cylinders, elliptical cylinders of two fineness ratios, rectangular and diamond cylinders of three fineness ratios, and two isosceles triangular cylinders (apex forward and base forward). Three different corner radii were tested. Data were obtained for Reynolds numbers as low as 11,000 and high as 2,300,000. Frequencies of pressure fluctuations in the wake were measured for some of the cylinders.

NACA TN 3039

EXPERIMENTAL STRESS ANALYSIS OF STIFFENED CYLINDERS WITH CUTOUTS. PURE TORSION. Floyd R. Schlechte and Richard Rosecrans. November 1953. 41p. diagrs., 7 tabs. (NACA TN 3039)

Torsion tests were made on a cylindrical semi-monocoque shell of circular cross section. The cylinder was first tested without a cutout, and then with a rectangular cutout which was successively enlarged through six sizes varying from 30° to 130° in circumference and from 1 to 2 bays in length. Strain measurements were made with resistance-type wire strain gages near the cutout on the stringers, the skin, and the rings for each size of cutout, and the stresses obtained are presented in tables.

NACA TN 3040

USE OF TWO-DIMENSIONAL DATA IN ESTIMATING LOADS ON A 45° SWEPTBACK WING WITH SLATS AND PARTIAL-SPAN FLAPS. Lynn W. Hunton and Harry A. James. November 1953. 40p. diagrs., photo., tab. (NACA TN 3040)

A study has been made of the application of two-dimensional data and span-loading theory for estimating the local loading characteristics on a swept wing with flaps. Estimated results, including local pressure distributions, span loadings, and the nonlinear local lift characteristics, are compared with similar results measured at a Reynolds number of 8 million on a 45° sweptback wing of aspect ratio 6 having a 0.4 span double-slotted flap both with and without a full-span slat. Two-dimensional pressure distributions when corrected for sweep were found to agree closely with the wing pressures for most local sections either on or off the flap, this agreement continuing to lift coefficients approaching those for stall.

NACA TN 3041

SUMMARY OF REVISED GUST-VELOCITY DATA OBTAINED FROM V-G RECORDS TAKEN ON CIVIL TRANSPORT AIRPLANES FROM 1933 TO 1950. Walter G. Walker. November 1953. 16p. diagrs., 4 tabs. (NACA TN 3041)

This paper summarizes gust-velocity data obtained by reevaluating the normal accelerations and airspeeds from V-G records taken on civil transport airplanes from 1933 to 1950. The reevaluation was made on the basis of a "derived" gust velocity U_{de}, which is related to the "effective" gust velocity U_e by a conversion factor that is a function of the type of airplane and operating altitude. Although the value of the conversion factor varies from about 1.6 to 2.0 for the data presented, the conclusions drawn from the previously presented data based on U_e (in particular the relative levels of turbulence indicated between different routes) remain essentially unchanged.

NACA TN 3043

APPLICATION OF SILVER CHLORIDE IN INVESTIGATIONS OF ELASTO-PLASTIC STATES OF STRESS. L. E. Goodman and J. G. Sutherland, University of Illinois. November 1953. 55p. diagrs., photos., 4 tabs. (NACA TN 3043)

Quantitative relationships between the state of elastic or plastic stress in a specimen and the observed relative retardation and extinction angle were developed from a general theory of stress birefringence, according to a stress-dependent hypothesis. The relationships were verified experimentally by measurements on single-crystal specimens of silver chloride tested in simple tension in the elastic and plastic stress ranges. Studies were also made of stress states in bicrystal tension specimens, in simple polycrystalline tension specimens, and in single-crystal and polycrystal tension specimens with holes and notches. Silver chloride appears to be a suitable medium for photoelastic studies of effects of plastic yielding on the state of stress in a crystalline specimen.

NACA TN 3044

EFFECT OF A RAPID BLADE-PITCH INCREASE ON THE THRUST AND INDUCED-VELOCITY RESPONSE OF A FULL-SCALE HELICOPTER ROTOR. Paul J. Carpenter and Bernard Fridovich. November 1953. 26p. diagrs., photos. (NACA TN 3044)

A method is developed for calculating the response of a helicopter rotor and its induced velocity buildup following a rapid blade-pitch increase. The calculated and experimental results are in good agreement for various rates of pitch increase of 6° to 200° per second.

NACA TN 3046

THEORETICAL CALCULATIONS OF THE EFFECTS OF FINITE SIDESLIP AT SUPERSONIC SPEEDS ON THE SPAN LOADING AND ROLLING MOMENT FOR FAMILIES OF THIN SWEPTBACK TAPERED WINGS AT AN ANGLE OF ATTACK. Windsor L. Sherman and Kenneth Margolis. November 1953. 53p. diagrs., tab. (NACA TN 3046)

By means of the expressions derived in NACA Technical Note 2898, the span load distributions for families of thin sweptback wings sideslipping at an angle of attack have been calculated. Variations of the rolling-moment coefficient C_l with sideslip angle and of the corresponding stability derivative C_{l_β} with Mach number are also presented. The results are applicable to plan forms for which the wing tips are parallel to the wing axis of symmetry and, in general, at supersonic speeds for which the trailing edge is supersonic.

NACA TN 3048

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF COOLING ON FRICTION AND ON BOUNDARY-LAYER TRANSITION FOR LOW-SPEED GAS FLOW AT THE ENTRY OF A TUBE. Stephen J. Kline and Ascher H. Shapiro, Massachusetts Institute of Technology. November 1953. 65p. diagrs., tab. (NACA TN 3048)

The effect of cooling on boundary-layer transition in the steady flow of air in the entrance of a smooth round tube was investigated experimentally. Runs were made at diameter Reynolds numbers varying from 50,000 to 106,000. The levels of disturbance were such as to yield adiabatic length Reynolds numbers, based on the length to the start of transition, ranging from 500,000 to 1,800,000. Temperature differences between the wall and the free stream up to 270° F were applied, but no significant effect of cooling on the point of transition was found. Precise data for local and mean apparent friction factors are presented for the adiabatic and cooled cases. For the laminar portion of the flow, the apparent friction factors are correlated and compared with simple theories.

NACA TN 3051

GUST LOADS AND OPERATING AIRSPEEDS OF ONE TYPE OF FOUR-ENGINE TRANSPORT AIRPLANE ON THREE ROUTES FROM 1949 TO 1953. Walter G. Walker. November 1953. 34p. diagrs., 4 tabs. (NACA TN 3051)

V-G data obtained from a four-engine civil transport airplane are analyzed to determine the magnitude and frequency of occurrence of gust loads and gusts. The influence of the gusts and operating speeds in rough air on the gust loads experienced is shown. Variations in roughness on the different routes due to changes in seasonal weather conditions are indicated. The results of the analysis are in general agreement with those from similar operations of other civil transports recently investigated.

NACA TN 3052

THE EFFECT OF VERTICAL CHINE STRIPS ON THE PLANING CHARACTERISTICS OF V-SHAPED PRISMATIC SURFACES HAVING ANGLES OF DEAD RISE OF 20° AND 40°. Walter J. Kapryan and George M. Boyd, Jr. November 1953. 38p. diagrs., photo., 2 tabs. (NACA TN 3052)

The effect of vertical chine strips on the planing characteristics of two prismatic surfaces having angles of dead rise of 20° and 40° has been determined as part of a general research investigation on planing surfaces. Wetted lengths, resistance, and

center-of-pressure location were determined at speed coefficients up to 25.0, load coefficients up to approximately 80.0, and trims up to 30°. In addition, comparisons of the more important planing characteristics are made with those for related surfaces having angles of dead rise of 0°, 20°, and 40°, and for surfaces having angles of dead rise of 20° and 40° with horizontal chine flare. These comparisons show that vertical chine strips are a more effective means of increasing the lift of a given surface than horizontal chine flare is. This increase in lift, however, is accompanied by a substantial increase in drag so that the lifting efficiency of the vertically flared surface is comparable to one having horizontal chine flare.

NACA RM E51F21

RESISTANCE OF VARIOUS MATERIALS TO ATTACK BY MOLTEN BISMUTH-LEAD EUTECTIC AT ELEVATED TEMPERATURES. James J. Gangler and Walter J. Engel. September 1951. 14p. diagrs., photos., 2 tabs. (NACA RM E51F21)

The resistance of 40 materials including alloys, ceramics, ceramals, and pure metals to attack by bismuth-lead eutectic at temperatures between 1500° and 2000° F was investigated. A velocity of 15 feet per second was maintained between the material surface and the bismuth-lead eutectic. Those materials found to be resistant to this attack included 17 of the ceramals and ceramics, graphite, and arc-cast molybdenum. All other materials investigated were appreciably attacked by the eutectic in the form of uniform attack, cavitation, or pitting, as indicated by metallographic analysis. No evidence of intergranular corrosion was observed in any of the materials studied in this investigation. Disintegration rates were estimated in mils per year from linear measurements taken before and after the specimens were subjected to attack by the molten eutectic.

NACA RM E53I14

EVAPORATION AND SPREADING OF ISOOCTANE SPRAYS IN HIGH-VELOCITY AIR STREAMS. Donald W. Bahr. November 1953. 35p. diagrs., tab. (NACA RM E53I14)

The evaporation and spreading in isooctane sprays were investigated over a range of air-flow and fuel-injection conditions common in ram-jet engines. The fuel was injected contrastream from a simple-orifice fuel injector into air flowing through a duct 8 inches in diameter. The measurements were made over the following ranges: air temperatures, 80° to 390° R; air velocities, 100 to 350 feet per second; air static pressures, 18 to 35 inches of mercury absolute; fuel-injection pressure drops, 25 to 85 pounds per square inch; diameters of fuel injector orifice, 0.024 to 0.041 inch; and axial distances from fuel injector, 5 to 18 inches. Over these ranges, expressions were obtained which related the evaporation and spreading of the sprays to the experimental variables.

NACA TM 1363

A NEW SIMPLE INTERFEROMETER FOR OBTAINING QUANTITATIVELY EVALUABLE FLOW PATTERNS. (Ein Neues, Sehr Einfaches Interferometer zum Erhalt Quantitativ Auswertbarer Strömungsbilder). S. F. Erdmann. November 1953. 62p. diagrs., photos. (NACA TM 1363. Trans. from Applied Scientific Research, v. B2)

The method described in this report makes it possible to obtain interferometer records with the aid of available schlieren optics by the addition of very simple expedients. Under certain conditions, the interferograms need not be inferior to those obtained by other methods. (However, one fundamental drawback of the method compared to the Mach-Zehnder interferometer lies in a relatively very poor light output.) The method is based on the fundamental concept of the phase-contrast process developed by Zernike but which has been enlarged to such an extent that it practically represents an independent interference method. The two light beams causing the interferences are not separated until immediately before photographing and up to that point are subject to the same effects. The theory is explained on a purely physical basis and illustrated and proved by experimental data. A number of typical cases are cited and some quantitative results reported.

NACA TM 1368

SUPERSATURATION IN THE SPONTANEOUS FORMATION OF NUCLEI IN WATER VAPOR. (Übersättigung bei der spontanen Keimbildung in Wasserdampf). Adolf Sander and Gerhard Damköhler. November 1953. 19p. diagrs. (NACA TM 1368. Trans. from Naturwissenschaften, v. 31, no. 39/40, September 24, 1943. p. 460-465).

The supersaturation of water vapor required for spontaneous formation of nuclei was measured in the temperature range between +35° and -75° C. The influence of the presence of ions on the condensation process was found to disappear and a break in the critical supersaturation as a function of temperature curve was found at -62° C. In addition, the condensate particles were observed to scintillate at -62° C or lower. A modified form of the Volmer and the Becker-Döring equations for rate of nucleus formation is presented and compared with the experimental data. The temperature range of droplet-nucleus formation and crystal-nucleus formation are considered as two distinct (not overlapping) temperature regions separated by the melting point (-62° C) of a two-dimensional surface phase.

THE AERODYNAMIC CHARACTERISTICS OF FLAPS. A. D. Young. 1953. 55p. diagrs., 2 tabs. (ARC R &M 2622; ARC 10,766. Formerly RAE Aero 2185)

This report collects and summarizes the results of work that has been done both in this and other countries on the aerodynamic characteristics of flaps prior to and during the period of the war. The report presents charts and tables which will enable designers to predict with acceptable accuracy the characteristics of any particular flap arrangement. In section 2, a brief description of the various flaps considered is given. Section 3 is devoted to a discussion of the definitions of the lift, drag, and pitching-moment increments, based on the normal and on the effective (extended or reduced) wing chords. Section 4 deals in some detail with split and plain flaps, while section 5 is devoted to the simple slotted flaps of the Handley Page and NACA types. A large variety of flaps classified as high-lift flaps are considered in section 6. These include Fowler flaps, double Fowler flaps, NACA single and double-slotted flaps, single and double Blackburn flaps, Blackburn flaps with flap leading-edge slots, Blackburn flaps with inset slots, Blackburn flaps with deflected shrouds, and Venition-blind flaps. The effect of wing-body interference on the drag and lift increments of split and slotted flaps is discussed in section 7, while section 8 summarizes the aerodynamic effects of wing leading-edge slots. The effect of flaps on induced drag is dealt with in section 9. A discussion of the characteristics of nose flaps, with particular reference to the type developed and tested by Kruger in Germany is given in section 10. A brief discussion on brake flaps is given in section 11, while the allied subject of dive recovery flaps is examined in section 12. Such information as is available on the characteristics of flaps on sweptback wings is summarized in section 13. Section 14 is devoted to a summary of the main formulas and conclusions developed in the report.

BOUNDARY-LAYER FLOW ALONG A FLAT PLATE WITH UNIFORM SUCTION. J. M. Kay. 1953. 28p. diagrs. (ARC R & M 2628. Formerly ARC 11,476; AC 137; FM 1244; Perf. 474; ARC 12,193; FM 1244a; Perf. 474a)

Experiments have been made to determine the effectiveness of distributed suction as a means of controlling and stabilizing the flow in a boundary layer. Good agreement has been obtained between the measured velocity profiles and the theoretical exponential form. The variation with rate of suction of the total effective drag of a flat plate has been investigated. In turbulent flow distributed suction provides an effective method of thinning a turbulent boundary layer.

THE DIFFUSION OF LOAD INTO A SEMI-INFINITE SHEET. PARTS I AND II. E. H. Mansfield. 1953. 61p. diagrs. (ARC R & M 2670; ARC 11,268; ARC 11,747. Formerly RAE Structures 11; RAE Structures 27)

In Part I, the rigorous and the "stringer-sheet" stress solutions are given for a point load applied in the plane of a semi-infinite sheet and at a finite distance from the boundary which is assumed to be free. From these are derived, by integration, some of the stresses produced by distributed loads applied along lines normal to the free boundary; attention is concentrated on the stresses along the line of action of the applied loads. The problem of finding the shear stresses adjacent to a load-carrying boom attached to the sheet and normal to the free edge is also investigated and integral equations for the shear stresses are derived. In Part II, a theoretical investigation is made into the problem of stiffening a sheet to relieve the high stresses near the free edge and adjacent to a direct load-carrying boom attached to the sheet. For booms of constant cross-section the stress distribution depends, with certain assumptions on two nondimensional parameters, and curves are included for determining the peak stresses in the sheet and the loads in the stiffening structure over the practical range of these parameters.

A COMPARISON OF TWO METHODS OF CALCULATING WING LOADING WITH ALLOWANCE FOR COMPRESSIBILITY. V. M. Falkner. With appendix: NOTE ON FALKNER'S METHOD FOR CALCULATING COMPRESSIBILITY EFFECTS OF WING LOADING. W. P. Jones. 1953. 53p. diagrs., 41 tabs. (ARC R &M 2685. Formerly ARC 11,944; S & C 2266; Perf. 507; FM 1312; ARC 12,650; ARC 12,147; Perf. 530; FM 1335; S & C 2302)

The report gives the results of a comparison by two different methods of the aerodynamic loading of a tapered V wing of aspect ratio 5.8 and 45° sweepback at $M = 0.8$ based on the Prandtl-Glauert factor or linear perturbation theory; the first method, associated particularly with vortex-lattice theory, deals with changes in Mach number by preserving the

plan of the wing and using special tables of downwash, while the second used the solution for Mach number 0 on a wing with the lateral dimensions reduced by a specified factor. Examples of the application of the theory are also given for a delta wing, for a straight tapered wing without sweep, and for a tapered wing with 28.4° sweepback. It is possible to give a general and reasonable explanation of the nature of the variations of load grading and local aerodynamic center which occur with increasing Mach number, and with the information given, there should be no difficulty in the prediction of Mach number effects on a wide range of plan forms.

SOME TESTS ON COMPRESSOR CASCADES OF RELATED AEROFOILS HAVING DIFFERENT POSITIONS OF MAXIMUM CAMBER. A. D. S. Carter. 1953. 17p. diagrs., photos., 2 tabs. (ARC R & M 2694; ARC 12,324. Formerly NGTE R. 47)

One of the major variables defining the shape of any blade is its position of maximum camber, and there are several indications that its choice considerably effects the performance of the cascade. Tests have therefore been carried out on a series of aerodynamically equivalent cascades in which the position of maximum camber was varied systematically. The tests covered a full incidence range up to choking.

THE CALCULATION OF WHIRLING SPEEDS OF A SYSTEM OF ROTORS KEYED TO CO-AXIAL SHAFTS. T. S. Wilson. 1953. 24p. diagrs. (ARC R & M 2709; ARC 12,266)

The calculation of whirling speeds of a "semirigid" system is brought within the scope of the iterative technique of Duncan and Collar. It is demonstrated by theory and example that problems involving large numbers of degrees of freedom may thereby be efficiently dealt with. An additional refinement of procedure allows two or more modes to be extracted more or less simultaneously from an iteration which is converging slowly. Only rotors having axial symmetry as regards mass are dealt with.

Aeronautical Research Council (Gt. Brit.)
THE CALCULATION OF LIFT TAKING ACCOUNT OF THE BOUNDARY LAYER. J. H. Preston. 1953. 40p. diagrs., 2 tabs. (ARC R & M 2725. Formerly ARC 12,747; FM 1397; Perf. 609; S & C 2351)

The purpose of this paper is to find a sound approach to the problem of the theoretical prediction of sectional characteristics taking account of the boundary layer. Attention is mainly concentrated on the lift, since it is on the accuracy of this calculation that the accuracy of calculations for other characteristics such as pressure distribution and moments must depend. Calculations of the lift and of the velocity at the edge of the boundary layer near the trailing edge have been made for two dissimilar symmetrical airfoils at an incidence of 6°, using boundary-layer data taken from experiment. The method of calculation satisfies the fundamental theorem that no net vorticity is discharged into the wake at the trailing edge and in contrast to the earlier calculations of R & M 1996, full account is now taken of the effect of the boundary layer on the velocity field outside the boundary layer, so that the empiricism of that report is avoided. The present calculations harmonize the two different methods of approach which have been used in the past, namely, the one in which the loss of lift below the Joukowski value was attributed entirely to the incidence and camber effects of the boundary layer, and the other in which the vorticity theorem was satisfied, but boundary-layer camber effects were ignored.

AERODYNAMIC FORCES ON BICONVEX AEROFOILS OSCILLATING IN A SUPERSONIC AIRSTREAM. W. P. Jones and Sylvia W. Skan.
EFFECT OF THICKNESS ON THE AERODYNAMIC FORCES ON BICONVEX AEROFOILS OSCILLATING IN A SUPERSONIC AIRSTREAM, AND CALCULATION OF FORCES FOR AEROFOIL WITH FLAP. Sylvia W. Skan. 1953. 34p. diagrs., 5 tabs. (ARC R & M 2749. Formerly ARC 13,162; FM 1443; 0.873; S & C 2401; ARC 14,217; 0.954)

In the first part of this report, a method for the calculation of the aerodynamic forces on an oscillating airfoil which allows for the effect of thickness is developed. Aerodynamic lift and pitching-moment derivatives for a 5-percent-thick, symmetrical, circular-arc airfoil at Mach numbers of 1.4, 1.5 and 2.0 are given for a range of frequencies and compared with values obtained on the basis of the flat plate theory. In the second part, the lift distribution and the aerodynamic force coefficients are calculated for a 7.5-percent-thick symmetrical circular-arc airfoil at Mach numbers of 2.0, 1.7 and 1.5 for a range of frequencies. These results are compared with those given in the first part for a 5-percent-thick airfoil, and with the values derived on the basis of flat plate theory.

EXPERIMENTS WITH STATIC TUBES IN A SUPERSONIC AIRSTREAM. PARTS I AND II. D. W. Holder, R. J. North and A. Chinneck. 1953. 14p. diagrs., photos., 2 tabs. (ARC R & M 2782. Formerly ARC 13,268; TP 309; FM 1463; ARC 13,269; TP 310; FM 1464)

Part I presents results of systematic tests made at a Mach number of 1.6 on a family of static tubes. The variables which were investigated are the shape of the nose, the distance of the holes downstream, and the inclination of the tube to the flow. Pressure measurements were also made in the vicinity of a shock wave and close to a wall. Part II presents the results of tests made of a family of flat-nosed pitot tubes at Mach numbers of 1.6 and 1.8. At both Mach numbers it was found that no change of reading could be detected when the ratio of the external diameter to the bore was varied from 2 to 16.

Advisory Group for Aeronautical Research and Development. SOME APPLICATIONS OF STRAIN GAGES IN AERONAUTICAL RESEARCH. Ira H. Abbott. FLIGHT TEST APPLICATIONS OF STRAIN GAGES. Walter K. Rickert. (Presented at Rome AGARD conference, December 12-19, 1952) 53p. diagrs., photos. (Advisory Group for Aeronautical Research and Development. AG2/M1)

The purpose of this report is to give information on the state of the art of strain-gage measurement of flight test quantities in the U. S. The applications made by the NACA of strain gages to aeronautical research are classified into three categories. First, the direct measurement of strain and stress in structures with reference to high-temperature applications is discussed. Secondly, the use of strain gages to measure the aerodynamic loads on aircraft in flight as experienced by the NACA is described. Thirdly, the use of strain gages in instrumentation is presented. The application of strain gages to wind tunnel balances is discussed in some detail. Application of strain gages to aircraft flight testing is considered, and their future use in the problem of servo operated control systems for aircraft is predicted.

DECLASSIFIED NACA REPORTS

NACA RM A7I10

INVESTIGATION OF WING CHARACTERISTICS AT A MACH NUMBER OF 1.53. I - TRIANGULAR WINGS OF ASPECT RATIO 2. Walter G. Vincenti, Jack N. Nielsen and Frederick H. Matteson. December 19, 1947. 83p. diagrs., photos., tab. (NACA RM A7I10) (Declassified from Confidential, 10/5/53)

Measurements of lift, drag, and pitching moment at M = 1.53 are described for three sharp-edged wing models having a triangular plan form of aspect ratio 2 and a common thickness ratio of 5 percent but varying in thickness distribution and camber. The experimental techniques are discussed and the results compared with the predictions of the linear theory.

NACA RM A8E05

INVESTIGATION OF WING CHARACTERISTICS AT A MACH NUMBER OF 1.53. II - SWEPT WINGS OF TAPER RATIO 0.5. Walter G. Vincenti, Milton D. Van Dyke and Frederick H. Matteson. June 28, 1948. 56p. diagrs., photos., 2 tabs. (NACA RM A8E05) (Declassified from Confidential, 10/5/53)

Measured values of lift, drag, and pitching moment at M_O = 1.53 are presented for seven wings varying in sweep angle from 60° sweepforward to 60° sweepback. All wings had a cambered, double-wedge section 5-percent thick and a common taper ratio of 0.5. The experimental results are compared with the predictions of the linear theory.

NACA RM A8E06

INVESTIGATION OF WING CHARACTERISTICS AT A MACH NUMBER OF 1.53. III - UNSWEPT WINGS OF DIFFERING ASPECT RATIO AND TAPER RATIO. Jack N. Nielsen, Frederick H. Matteson and Walter G. Vincenti. June 21, 1948. 64p. diagrs., photos., tab. (NACA RM A8E06) (Declassified from Confidential, 10/5/53)

Measured values of lift, drag, and pitching moment at M = 1.53 are presented for seven unswept wings varying in aspect ratio from 1 to 6 and in taper ratio from 0 to 1. All wings had an isosceles-triangle section 5-percent thick. The experimental results are compared with the predictions of linear theory.

NACA RM L6J01a

AN INVESTIGATION OF THE EFFECTS OF SWEEP ON THE CHARACTERISTICS OF A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Richard T. Whitcomb. February 14, 1947. 74p. diagrs., photos., 4 tabs. (NACA RM L6J01a) (Declassified from Restricted, 8/14/53)

An untwisted wing, which when unswept has an NACA 65-210 section, an aspect ratio of 9.0 and a taper ratio of 2.5:1.0, has been tested with no sweep, and 30° and 45° of sweepback and sweepforward in conjunction with a typical fuselage at Mach numbers from 0.60 to 0.96 at angles of attack generally between -2° and 10° in the Langley 8-foot high-speed tunnel. Sweep was obtained by rotating the wing semispans about a point in the plane of symmetry. The normal-force, pitching-moment, profile-drag, and loading characteristics for the wings have been obtained from pressure measurements and wake surveys.

NACA RM L6J16

DRAG CHARACTERISTICS OF RECTANGULAR AND SWEPT-BACK NACA 65-009 AIRFOILS HAVING ASPECT RATIOS OF 1.5 AND 2.7 AS DETERMINED BY FLIGHT TESTS AT SUPERSONIC SPEEDS. Sidney R. Alexander and Ellis Katz. February 24, 1947. 19p. diagrs., photos. (NACA RM L6J16) (Declassified from Confidential, 10/21/53)

Tests were conducted to determine the effect of sweepback angle and aspect ratio on the drag of an NACA 65-009 airfoil at supersonic speeds. The data were obtained by tracking rocket-propelled bodies carrying wings of various plan forms. The following wing arrangements were investigated: (a) aspect ratio of 1.5, sweepback angles of 0°, 34°, 45°, and 52°, and (b) aspect ratio of 2.7, sweepback angles of 0°, 34°, and 45°.

NACA RM L6J16a

FLIGHT TESTS TO DETERMINE THE EFFECT OF LENGTH OF A CONICAL WINDSHIELD ON THE DRAG OF A BLUFF BODY AT SUPERSONIC SPEEDS. Sidney R. Alexander and Ellis Katz. January 29, 1947. 13p. diagrs., photo. (NACA RM L6J16a) (Declassified from Confidential, 10/21/53)

Flight tests have been conducted to determine the effect of length of a conical windshield on the drag of a bluff body moving at supersonic speeds. A comparison is made between results thus obtained (for a 3-inch windshield) and the results of previous drag tests of body-windshield combinations (for windshields of 0, 1-inch, and 10-inch length).

NACA RM L6K08a

RESULTS OF TESTS TO DETERMINE THE EFFECT OF A CONICAL WINDSHIELD ON THE DRAG OF A BLUFF BODY AT SUPERSONIC SPEEDS. Sidney R. Alexander. January 14, 1947. 12p. diagrs., photos. (NACA RM L6K08a) (Declassified from Confidential, 10/21/53)

Tests have been conducted to determine the effect of a conical windshield on the drag of a bluff body at supersonic speeds. The following configurations were investigated: a sharp-nose fuselage with stabilizing fins, a blunt-nose fuselage obtained by rounding off the sharp nose to a hemispherical shape, and a blunt-nose fuselage with a conical point, or windshield, having the same nose angle as the original sharp nose and supported at the same position.

NACA RM L7B12

AN INVESTIGATION OF THE DOWNWASH AT THE PROBABLE TAIL LOCATION BEHIND A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Richard T. Whitcomb. April 22, 1947. 12p. diagrs. (NACA RM L7B12) (Declassified from Restricted, 10/21/53)

Downwash angles have been measured behind a model of a high-aspect-ratio wing at points near the probable tail location at Mach numbers up to 0.89 in the Langley 8-foot high-speed tunnel. The model has an NACA 65-210 section, an aspect ratio of 9.0, a taper ratio of 2.5:1, no twist, dihedral, or sweepback.

NACA RM L7B19

RESULTS OF FLIGHT TESTS AT SUPERSONIC SPEEDS TO DETERMINE THE EFFECT OF BODY NOSE FINENESS RATIO ON BODY AND WING DRAG. Ellis R. Katz. June 26, 1947. 14p. diagrs., photo. (NACA RM L7B19) (Declassified from Confidential, 10/21/53)

Flight tests of rocket-powered models at supersonic speeds have been made to determine the effect of nose fineness ratio of winged bodies on total and component drag at high Mach numbers. Wingless models of three nose fineness ratios and winged models of two nose fineness ratios were flown through a Mach number range up to 1.4.

NACA RM L7D02

FREE-FLIGHT INVESTIGATION OF CONTROL EFFECTIVENESS OF FULL-SPAN 0.2-CHORD PLAIN AILERONS AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS TO DETERMINE SOME EFFECTS OF SECTION THICKNESS AND WING SWEEPBACK. Carl A. Sandahl and Alfred A. Marino. May 29, 1947. 14p. diagrs., photos., tab. (NACA RM L7D02) (Declassified form Confidential, 10/21/53)

A rocket-propelled test vehicle to be used in an experimental investigation of aerodynamic control effectiveness at high subsonic, transonic, and supersonic speeds has been developed. The test vehicle (RM-5) and the instrumentation are described and the first data obtained are presented. These data indicate some of the effects of section thickness ratio and wing sweepback on the rolling effectiveness of plain full-span 0.2-chord ailerons deflected 5°.

NACA RM L7D21

AN INVESTIGATION OF THE LATERAL-CONTROL CHARACTERISTICS OF SPOILERS ON A HIGH-ASPECT-RATIO WING OF NACA 65-210 SECTION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Arvo A. Luoma. June 24, 1947. 124p. diagrs., photos., 2 tabs. (NACA RM L7D21) (Declassified from Restricted, 10/21/53)

A three-dimensional lateral-control investigation was made of 3- and 6-percent-chord spoilers projecting on the upper surface of a wing of high-aspect ratio. The spoilers were located ahead of conventional 0.20-chord straight-sided-profile plain ailerons and tests were made with the spoilers at the 60- and 70-percent-chord locations. Ailerons and spoilers had the same span of 37.5-percent wing semispan. Spanwise loadings and moments and rolling-moment coefficients were determined from pressure distribution measurements. Hinge-moment data for the conventional aileron were obtained by an electrical strain gage. Data were obtained for Mach numbers up to 0.925.

NACA RM L7I15

HIGH-SPEED WIND-TUNNEL INVESTIGATION OF THE LATERAL CONTROL CHARACTERISTICS OF PLAIN AILERONS ON A WING WITH VARIOUS AMOUNTS OF SWEEP. Arvo A. Luoma, Ralph P. Bielat and Richard T. Whitcomb. December 19, 1947. 67p. diagrs., 3 tabs. (NACA RM L7I15) (Declassified from Restricted, 10/21/53)

Rolling-moment, wing normal-force, wing pitching-moment, and aileron hinge-moment coefficients are presented from tests of straight-sided profile plain ailerons on a wing with 30° and 45° of sweepback and sweepforward for aileron deflections from -10° to 10° at Mach numbers from 0.60 to 0.96. In general, 30° of sweep reduced the large changes of rolling- and aileron hinge-moment coefficients observed on an unswept wing and delayed the speed at which such changes occurred. With 45° of sweep, these characteristics were not materially changed over the speed range covered.

CURRENT NACA REPORTS

NACA Rept. 1117

A STUDY OF ELASTIC AND PLASTIC STRESS CONCENTRATION FACTORS DUE TO NOTCHES AND FILLETS IN FLAT PLATES. Herbert F. Hardrath and Lachlan Ohman. 1953. ii, 10p. diagrs., tab. (NACA Rept. 1117. Formerly TN 2566)

Six large 24S-T3 aluminum-alloy-sheet specimens containing various notches or fillets were tested in tension to determine their stress concentration factors in the elastic and plastic ranges. The elastic stress concentration factors were found to be slightly higher than those predicted by other methods. A generalization of a relation presented by Stowell gave good agreement with the plastic stress concentration factors as they decreased with increasing plastic strain.

NACA TN 3029

A FUNDAMENTAL INVESTIGATION OF FRETTING CORROSION. H. H. Uhlig, I. Ming Feng, W. D. Tierney, and A. McClellan, Massachusetts Institute of Technology. December 1953. 52p. diagrs., photos., 2 tabs. (NACA TN 3029)

This report summarizes all phases of an investigation of fretting corrosion which has been conducted over a period of several years. The presentation of the information is made in three parts. Part I describes a test machine for measuring fretting damage under controlled experimental conditions. Part II presents data for mild steel fretted against itself. Consideration is given to the effects of humidity, temperature, test duration, atmosphere, relative slip, pressure, and frequency. Part III suggests a mechanism for the fretting process.

NACA TN 3047

IMPINGEMENT OF WATER DROPLETS ON NACA 65A004 AIRFOIL AND EFFECT OF CHANGE IN AIRFOIL THICKNESS FROM 12 TO 4 PERCENT AT 4° ANGLE OF ATTACK. Rinaldo J. Brun, Helen M. Gallagher and Dorothea E. Vogt. November 1953. 45p. diagrs., tab. (NACA TN 3047)

The trajectories of droplets in the air flowing past an NACA 65A004 airfoil at an angle of attack of 4° were determined. The amount of water in droplet form impinging on the airfoil, the area of droplet impingement, and the rate of droplet impingement per unit area on the airfoil surface were calculated from the trajectories and presented to cover a large range of flight and atmospheric conditions. The effect of a change in airfoil thickness from 12 to 4 percent at 4° angle of attack is presented by comparing the impingement calculations for the NACA 65A004 airfoil with those for the NACA 65_1-208 and 65_1-212 airfoils. The rearward limit of impingement on the upper surface decreases as the airfoil thickness decreases. The rearward limit of impingement on the lower surface increases with a decrease in airfoil thickness. The total water intercepted decreases as the airfoil thickness is decreased.

NACA TN 3049

AN ANALYTICAL INVESTIGATION OF THE EFFECT OF THE RATE OF INCREASE OF TURBULENT KINETIC ENERGY IN THE STREAM DIRECTION ON THE DEVELOPMENT OF TURBULENT BOUNDARY LAYERS IN ADVERSE PRESSURE GRADIENTS. Bernard Rashis. November 1953. 30p. diagrs., 2 tabs. (NACA TN 3049)

A general integral form of the boundary-layer equation which includes the Reynolds normal-stress term is derived. Two special equations are obtained from the general form. They are the modified momentum equation and the modified kinetic-energy equation. In addition, the parameters which control the dissipation of mean-flow kinetic energy by the shearing stress and the Reynolds normal stress are suggested.

NACA TN 3056

A FLIGHT INVESTIGATION OF LAMINAR AND TURBULENT BOUNDARY LAYERS PASSING THROUGH SHOCK WAVES AT FULL-SCALE REYNOLDS NUMBERS. Eziaslav N. Harrin. December 1953. 20p. diagrs., photos. (NACA TN 3056)

An investigation was made in flight at free-stream Mach numbers up to about 0.76 and Reynolds numbers up to about 26×10^6 to determine the behavior of laminar and turbulent boundary layers passing through shock waves. Boundary-layer and pressure-distribution measurements were made on a short-span airfoil built around a wing of a fighter airplane. The free-stream Mach numbers reached in the tests were sufficiently high to give extensive regions of local supersonic flow. Comparison is made with results of tests at low Reynolds numbers (up to 1/10-scale) of other investigations.

Royal Aircraft Establishment (Gt. Brit.)
THE CALCULATION OF THE PRESSURE DISTRIBUTION OVER THE SURFACE OF TWO-DIMENSIONAL AND SWEPT WINGS WITH SYMMETRICAL AEROFOIL SECTIONS. J. Weber. July 1953. 84p. diagrs., 13 tabs. (RAE Aero 2497. Rewritten and amended version of RAE Aero 2391)

A simple method is described for calculating the pressure distribution on the surface of a thick two-dimensional airfoil section, at any incidence, in incompressible potential flow. It is particularly suitable for practical applications, since knowledge of the section ordinates only is required. This paper gives a complete derivation of the theory including a detailed discussion of the approximations made and their effect on the accuracy of the results. The pressure distributions calculated by the present method are identical with the exact values for airfoils of elliptic cross section, and the numerical values for Joukowsky airfoils agree well with the exact solutions.

DESIGN AND CALIBRATION AT LOW SPEEDS OF A STATIC TUBE AND A PITOT-STATIC TUBE WITH SEMI-ELLIPSOIDAL NOSE SHAPES. D. J. Kettle. May 1953. 31p. diagrs., 5 tabs. (RAE Tech. Note Aero 2247)

A new static tube and a new pitot-static tube have been designed and calibrated in the No. 1 and the No. 2 11-1/2 foot by 8-1/2 foot wind tunnels of the R. A. E., using a long static tube, the error of which is believed to be very small, as a standard for comparison. The results show that the static pressure measured by these tubes is in error due to the supporting strut and to the nose shape of the tube by an amount which may be calculated for positions of the static slot, or holes, greater than 10 tube diameters ahead of the strut. The readings show no measurable scale effect in the speed range 100-230 ft/sec. The static tube is insensitive to yaw in the range $\pm 1^{o}$ with a square-edged slot and is even less sensitive to yaw when the slot edges are rounded. The turbulence of the tunnel has an effect on the static-pressure reading.

Royal Aircraft Establishment (Gt. Brit.)
COMPRESSIBILITY EFFECT ON GUST LOADS. J. K. Zbrozek. August 1953. 20p. diagrs. (RAE Tech. Note Aero 2254)

Theoretical calculations of the gust alleviation factor for a range of Mach numbers show an appreciable decrease in its value with increasing Mach number. The reduction in the value of the gust factor at $M = 0.7$ is about 10 percent for sharp-edged gusts and lightly loaded aircraft ($\mu_g = 20$) and decreases to about 5 percent for gust length of 10 chords and heavy aircraft ($\mu_g = 100$). The analysis of existing flight records indicates that the gust loads at high Mach numbers can be estimated satisfactorily if the gust factor and the lift slope are corrected for compressibility.

WIDE RANGE AMPLIFIER FOR TURBULENCE MEASUREMENTS WITH ADJUSTABLE UPPER FREQUENCY LIMIT. H. Schuh and D. Walker. August 1953. 42p. diagrs. (RAE Aero 2492)

The amplifier described in this report was originally planned for turbulence work at supersonic speeds; it was soon apparent that with some modifications, the same equipment could be used also at subsonic speeds. In its final version, it is suitable for measuring subsonic wind-tunnel turbulence of low intensity.

N-27059*

Royal Aircraft Establishment (Gt. Brit.)
THE TIME VECTOR METHOD FOR STABILITY INVESTIGATIONS. K. H. Doetsch. August 1953. 50p. diagrs., tab. (RAE Aero 2495)

A semigraphical method for the analysis of aircraft stability oscillations is described. It is based on the concept of rotating time vectors representing the forces and moments acting on the aircraft. Rules are developed for the application to damped and divergent oscillations. The method is iterative, simple and rapid. Close correlation with the physical facts of the motion is maintained and the contribution of each force and moment can be visualized. The immediate deduction of approximate formulas and their limitations is demonstrated and the application of the method to automatic control is discussed.

INTEGRATION OF THE EQUATIONS OF TRANSONIC FLOW IN TWO DIMENSIONS. D. Meksyn. November 25, 1952. 23p. 2 tabs. (ARC 15,412; FM 1819)

The problem of integration of the equations of compressible flow past a solid body has been considered in numerous papers. The solutions have been quite laborious. In this paper, a method is given in which the integration leads to an algebraic equation of the fifth degree which can be evaluated at any given point. The critical point of this equation determines the critical Mach number when a shock wave first appears. The method is applied to the motion past a circular cylinder and to the flow past an airfoil of thickness 1/10 consisting of two arcs with cusps at the leading and trailing edges. The results agree with Kaplan's calculations.

NACA RM L52E22

NOTES ON THE GUST PROBLEM FOR HIGH-SPEED LOW-ALTITUDE BOMBERS. Langley Gust Loads Branch. June 5, 1952. 23p. diagrs., 3 tabs. (NACA RM L52E22)

Available information pertaining to the gust problem for the high-speed low-altitude bomber has been collected and coordinated. Gust data of interest in this special problem have been presented and the general information for design has been indicated.

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL TO UNCLASSIFIED, 11/10/53.

NACA RM L6J14

DRAG MEASUREMENTS OF SYMMETRICAL CIRCULAR-ARC AND NACA 65-009 RECTANGULAR AIRFOILS HAVING AN ASPECT RATIO OF 2.7 AS DETERMINED BY FLIGHT TESTS AT SUPERSONIC SPEEDS. Sidney R. Alexander. March 7, 1947. 10p. diagrs., photo. (NACA RM L6J14)

Flight tests have been conducted at supersonic speeds to determine the drag characteristics at zero lift of a wing having a circular-arc airfoil section with a maximum thickness of 9 percent chord. The wing plan form was rectangular and had an aspect ratio of 2.7. Included for comparison are results of similar tests previously conducted on an NACA 65-009 airfoil. For the Mach number range investigated (0.85 to 1.22), the NACA 65-009 airfoil produced lower values of drag coefficient than the circular-arc airfoil.

NACA RM L6J23

RESULTS OF PRELIMINARY FLIGHT INVESTIGATION OF AERODYNAMIC CHARACTERISTICS OF THE NACA TWO-STAGE SUPERSONIC RESEARCH MODEL RM-1 STABILIZED IN ROLL AT TRANSONIC AND SUPERSONIC VELOCITIES. Marvin Pitkin, William N. Gardner and Howard J. Curfman, Jr. March 19, 1947. 55p. diagrs., photos. (NACA RM L6J23)

The design of a two-stage, solid-fuel, rocket propelled, general research pilotless aircraft (RM-1) suitable for investigating stability and control at supersonic velocities is discussed. The flight-test investigation conducted thus far is discussed and information is presented on zero-length launchers and operational flight-test techniques of two-stage rockets.

NACA RM L6K08c

DRAG MEASUREMENTS AT TRANSONIC SPEEDS OF NACA 65-009 AIRFOILS MOUNTED ON A FREELY FALLING BODY TO DETERMINE THE EFFECTS OF SWEEPBACK AND ASPECT RATIO. Charles W. Mathews and Jim Rogers Thompson. January 22, 1947. 14p. diagrs., photos. (NACA RM L6K08c)

Drag measurements at transonic speeds on rectangular airfoils and on airfoils swept back 45° are reported. These airfoils, which were mounted on cylindrical test bodies, are part of a series being tested in free drops from high altitude to determine the effect of variation of basic airfoil parameters on airfoil drag characteristics at transonic speeds. These rectangular and sweptback airfoils had the same span, airfoil section (NACA 65-009), and chord perpendicular to the leading edge. The tests were made to compare the drag of rectangular and sweptback airfoils at a higher aspect ratio than had been used in a similar comparison reported previously.

NACA RM L52E05 ~ BCL -

PRELIMINARY EXPERIMENTS ON THE ELASTIC COMPRESSIVE BUCKLING OF PLATES WITH INTEGRAL WAFFLE-LIKE STIFFENING. Norris F. Dow and William A. Hickman. July 1952. 13p. diagrs., photo., tab. (NACA RM L52E05)

An experimental investigation was made of the elastic compressive buckling strength of plates having various configurations of integral stiffening. Configurations tested included ribbing that was longitudinal, transverse, longitudinal and transverse, and skewed at various angles to the sides of the plates to form a diamond or waffle-like pattern. The 45° waffle stiffening was found to be the most effective of all those considered, giving a buckling load nearly double that for the same waffle pattern with the ribbing longitudinal and transverse.

NACA RM L53E13a

FORMULAS FOR THE ELASTIC CONSTANTS OF PLATES WITH INTEGRAL WAFFLE-LIKE STIFFENING. Norris F. Dow, Charles Libove and Ralph E. Hubka. Ausust 1953. 67p. diagrs., tab. (NACA RM L53E13a)

Formulas are derived for the elastic constants of plates with integral ribbing. The constants, which include the effectiveness of the ribs for resisting deformations other than bending and stretching in their longitudinal directions, are defined in terms of four coefficients, and methods for the evaluation of these coefficients are discussed. Four of the more important elastic constants are predicted by these formulas and are compared with test results.

CURRENT NACA REPORTS

NACA Rept. 1096

EXPERIMENTAL DETERMINATION OF THE EFFECT OF HORIZONTAL-TAIL SIZE, TAIL LENGTH, AND VERTICAL LOCATION ON LOW-SPEED STATIC LONGITUDINAL STABILITY AND DAMPING IN PITCH OF A MODEL HAVING 45° SWEPTBACK WING AND TAIL SURFACES. Jacob H. Lichtenstein. 1952. ii, 22p. diagrs., photos., 3 tabs. (NACA Rept. 1096. Formerly TN 2381; TN 2382)

An investigation has been conducted in the Langley stability tunnel to determine the effects of horizontal tails of various sizes and at various tail lengths (when located on the fuselage center line) and also the effects of vertical location of the horizontal tail relative to the wing on the low-speed static longitudinal stability and on the steady-state rotary damping in pitch for a complete-model configuration. The wing and tail surfaces had the quarter-chord lines swept back 45° and had aspect ratios of 4.

NACA Rept. 1098

SUMMARY OF METHODS FOR CALCULATING DYNAMIC LATERAL STABILITY AND RESPONSE AND FOR ESTIMATING LATERAL STABILITY DERIVATIVES. John P. Campbell and Marion O. McKinney. 1952. ii, 40p. diagrs., 2 tabs. (NACA Rept. 1098. Formerly TN 2409)

A summary of methods for making dynamic lateral stability and response calculations and for estimating the aerodynamic stability derivatives required for use in these calculations is presented. The processes of performing calculations of the time histories of lateral motions, of the period and damping of these motions, and of the lateral stability boundaries are presented as a series of simple straightforward steps. Existing methods for estimating the stability derivatives are summarized and, in some cases, simple new empirical formulas are presented. Detailed estimation methods are presented for low-subsonic-speed conditions but only a brief discussion and a list of references are given for transonic- and supersonic-speed conditions.

NACA Rept. 1102

THE LINEARIZED CHARACTERISTICS METHOD AND ITS APPLICATION TO PRACTICAL NON-LINEAR SUPERSONIC PROBLEMS. Antonio Ferri. 1952. ii, 18p. diagrs. (NACA Rept. 1102. Formerly TN 2515)

The method of characteristics has been linearized by assuming that the flow field can be represented as a basic flow field determined by nonlinearized methods and a linearized superposed flow field that considers small changes in boundary conditions. The method has been applied to two-dimensional rotational flow, to calculations of axially symmetric flow, to slender bodies without symmetry, and to wing problems.

NACA Rept. 1104

PRELIMINARY INVESTIGATION OF A NEW TYPE OF SUPERSONIC INLET. Antonio Ferri and Louis M. Nucci. 1952. ii, 19p. diagrs., photos., tab. (NACA Rept. 1104. Formerly TN 2286)

A supersonic inlet with supersonic deceleration of the flow entirely outside of the inlet is considered. A particular arrangement with fixed geometry having a central body with a circular annular intake is analyzed, and it is shown theoretically that this arrangement gives high pressure recovery for a large range of Mach number and mass flow and, therefore, is practical for use on supersonic airplanes and missiles. Experimental results confirming the theoretical analysis give pressure recoveries which vary from 95 percent for Mach number 1.33 to 86 percent for Mach number 2.00. These results were originally presented in a classified document of the NACA in 1946.

NACA TN 3055

FRICTION AND WEAR INVESTIGATION OF MOLYBDENUM DISULFIDE. I - EFFECT OF MOISTURE. Marshall B. Peterson and Robert L. Johnson. December 1953. 28p. diagrs., photos. (NACA TN 3055)

Low-speed kinetic friction studies show that for molybdenum disulfide MoS_2 lubricated steel surfaces coefficients of friction were greater at high humidity than with dry air. MoS_2 powder did not adhere to steel surfaces at high humidity, and as a result, metallic contact was greater and friction and wear increased. Increased wear with greater humidity may have been caused by corrosion of steel specimens by acids formed on contact of moisture with MoS_2. Variations in shear area resulted from changes in humidity, slider geometry, surface finish, and method of film application. Larger shear areas caused greater friction when MoS_2 filled the surface interstices and was sheared.

NACA TN 3058

TRANSIENT TEMPERATURE DISTRIBUTIONS IN SIMPLE CONDUCTING BODIES STEADILY HEATED THROUGH A LAMINAR BOUNDARY LAYER. Hermon M. Parker. December 1953. 42p. diagrs. (NACA TN 3058)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

An analysis is made of the transient heat-conduction effects in three simple semi-infinite bodies: the insulated flat plate, the conical shell, and the slender solid cone. The bodies are assumed to have constant initial temperatures and at zero time to begin to move at a constant speed and zero angle of attack through a homogeneous atmosphere. The heat input is taken as that through a laminar boundary layer. Radiation heat transfers and transverse temperature gradients are assumed to be zero. The appropriate heat-conduction equations are solved by an iteration method, the zeroeth order terms describing the situation in the limit of small time. The method is presented and the solutions are calculated to three orders which are sufficient to give reasonably accurate results when the forward edge has attained one-half the total temperature rise (nose half-rise time). Flight Mach number and air properties occur as parameters in the result. Approximate expressions for the extent of the conduction region and nose half-rise times as functions of the parameters of the problem are presented.

NACA TN 3087

EXPERIMENTAL INVESTIGATION OF TWO-DIMENSIONAL TUNNEL-WALL INTERFERENCE AT HIGH SUBSONIC SPEEDS. Earl D. Knechtel. December 1953. 13p. diagrs. (NACA TN 3087)

Results are shown of an investigation of tunnel-wall interference in a two-dimensional-flow, rectangular, closed-throat wind tunnel through a Mach number range from 0.3 to 0.9 and a corresponding Reynolds number range from 0.9×10^6 to 1.8×10^6. For ratios of airfoil chord to tunnel height below approximately 0.15, correction of aerodynamic data for wall interference by the small-perturbation theory of NACA Rep. 782 was found to yield results in satisfactory agreement with essentially interference-free data.

NACA TN 3089

ONE-DIMENSIONAL, COMPRESSIBLE, VISCOUS FLOW RELATIONS APPLICABLE TO FLOW IN A DUCTED HELICOPTER BLADE. John R. Henry. December 1953. 16p. diagrs. (NACA TN 3089)

One-dimensional, steady-state, compressible, viscous flow relations are presented which permit the determination of flow conditions at any radial position in a ducted helicopter blade. The relations are required for estimating the performance of proposed helicopter jet-propulsion systems which involve ducting air or gases through the blade from root to tip. A limited number of calculations over a wide range of helicopter operating conditions and relative duct sizes are also presented. The "choking" problem in the straight duct is discussed.

NACA TN 3090

INVESTIGATION OF SANDWICH CONSTRUCTION UNDER LATERAL AND AXIAL LOADS. Wilhelmina D. Kroll, Leonard Mordfin and William A. Garland, National Bureau of Standards. December 1953. 58p. diagrs., photos., 4 tabs. (NACA TN 3090)

Tests under combined axial load and lateral pressure were made of sandwich panels with simply supported loaded edges and free unloaded edges to determine the strength of panels of various thicknesses and to compare the results with computed values. The theory, derived in this paper, is based on the theory for buckling of simply supported sandwich columns and was conservative in predicting larger strains or deflections than those measured. Agreement between computed maximum loads and experimental failing loads was within 9 percent.

NACA TN 3093

EFFECT OF TYPE OF POROUS SURFACE AND SUCTION VELOCITY DISTRIBUTION ON THE CHARACTERISTICS OF A 10.5-PERCENT-THICK AIRFOIL WITH AREA SUCTION. Robert E. Dannenberg and James A. Weiberg. December 1953. 59p. diagrs., photos., 5 tabs. (NACA TN 3093)

Results are presented of an investigation of a two-dimensional, 10.51-percent-thick symmetrical airfoil with area suction near the leading edge. Lift and suction-flow characteristics were determined with different porous surfaces (perforated plates and sintered steel) for various suction velocity distributions. The flow requirements were ascertained over a range of free-stream velocities. The maximum lift was independent of the surface of the materials tested.

NACA RM E53J12

EFFECT OF DIFFUSION PROCESSES AND TEMPERATURE ON SMOKING TENDENCIES OF LAMINAR DIFFUSION FLAMES. Rose L. Schalla. December 1953. 23p. diagrs., photos. (NACA RM E53J12)

The effects of diffusion processes on the smoking tendencies of eight laminar diffusion flames were investigated by varying the rate and concentration of air and oxygen supplied to the flame. Increasing the rate at which air was supplied permitted rather limited increases in the smoke-free burning rate. Increasing the concentration of oxygen from 21 to 45 percent increased the smoke-free fuel flow for pentene-1, neopentane, isobutane, ethylene, and n-butane, but decreased the smoke-free burning rate for butene-1, cyclopropane, and propene in the range of 25 to 40 percent oxygen. Increasing the flame temperature caused the smoke-free fuel flow to increase except for butene-1, cyclopropane, and propene, where initial rates were lower. The variations in smoke formation with oxygen enrichment were tentatively explained by considering the effect of temperature on the initial decomposition reactions of the fuel molecule.

BRITISH REPORTS

N-27230*

Aeronautical Research Council (Gt. Brit.)
DYNAMIC LONGITUDINAL STABILITY MEASUREMENTS ON A SINGLE-ROTOR HELICOPTER (HOVERFLY MK. I). W. Stewart. With an appendix on THE THEORETICAL ESTIMATION OF THE STABILITY. G. J. Sissingh. 1953. 24p. diagrs. (ARC R & M 2505; ARC 11,578. Formerly RAE Aero 2244)

Flight measurements have been made of the phugoid motion of the Hoverfly Mk. I helicopter, following an arbitrary longitudinal displacement of the control, the latter being returned to its initial position and held fixed. The tests were done throughout the speed range for power-on conditions and in autorotation for various center-of-gravity positions and for forward and backward initial displacement of the stick.

TESTS ON THE HURRICANE L. 1696 IN THE 24-FT WIND TUNNEL. D. W. Bottle and T. V. Somerville. 1953. 10p. diagrs., photo., 5 tabs. (ARC R & M 2562; ARC 5344. Formerly RAE BA 1697)

Tests on a Hurricane in the 24-foot wind tunnel at the Royal Aircraft Establishment were required to find if any simple modifications could be made which would reduce its drag. Measurements were made of: (1) leak drag, (2) drag of miscellaneous excrescences, (3) cooling drag, and (4) drag of the tail unit. The tests showed that the leak drag plus the drag due to the control gaps was 13 percent of the total profile drag of the aircraft. Of this leak drag, only one-third could be eliminated by methods which could be incorporated in production aircraft without serious modification. This emphasizes the importance of eliminating leaks in the design stage. The drag of the cooling system was reasonably low, and tail-fuselage interference was small.

LANDING OF AN AIRCRAFT ON A SUSPENDED SHEET. J. Taylor. 1953. 37p. diagrs., 3 tabs. (ARC R & M 2574; ARC 10,643. Formerly RAE Structures 3)

An investigation is made into the characteristics of a freely suspended flexible sheet as a shock absorber replacing the conventional undercarriage, particular attention being given to the inertia of the sheet. It is found that when an aircraft is dropped vertically on to the sheet the retarding force is first produced by the inertia of the sheet itself, and not until later in the descent by the reactions from the side supports of the sheet. By careful adjustments of the mass and tension of the sheet "retardation efficiencies" exceeding 80 percent can be achieved. The effect of the aircraft having a forward component of velocity increases the contribution of sheet momentum. For reasonably practical landing speeds and sheet dimensions, virtually the whole of the momentum of descent is absorbed by sheet inertia. Under such conditions still higher retardation efficiencies are obtainable and, with a suitable design of aircraft keel, rebound may be entirely eliminated.

WIND-TUNNEL TESTS ON THE 30 PERCENT SYMMETRICAL GRIFFITH AEROFOIL WITH DISTRIBUTED SUCTION OVER THE NOSE. N. Gregory, W. S. Walker and A. N. Devereux. 1953. 14p. diagrs., photos. (ARC R & M 2647. Formerly ARC 11,599; Perf. 461; FM 1260)

This report describes tests carried out on the 30 percent Griffith symmetrical airfoil with continuous suction applied through a porous capping fitted over the front 15 percent of the upper surface. Throughout the range of incidence covered in the experiments, distributed suction was found to decrease the slot suction necessary to prevent separation, especially when the distributed suction caused rearward movement of the transition position. The profile drag of the airfoil was measured, and estimates were made of the equivalent drag coefficients for the work done by the suction pumps. Assuming no losses additional to those in the boundary layer, it was found that the effect of distributed suction was to reduce slightly the overall drag of the airfoil. Measurements of the velocity within the boundary layer were made at various chordwise positions on the porous surface; the profiles recorded were very close to the theoretical. Distributed suction was able to delay transition when this would otherwise be precipitated by a ridge on the surface, or by adverse pressure gradients, but a turbulent boundary layer remained turbulent when suction was applied. The characteristic spread of turbulent flow in the wake of a small particle on the surface was much reduced by distributed suction; under favorable conditions, the wake was entirely eliminated.

AEROFOIL OSCILLATIONS AT HIGH MEAN INCIDENCES. W. P. Jones. 1953. 9p. diagrs. (ARC R & M 2654. Formerly ARC 11,502; 0.724)

The problem of the estimation of the aerodynamic forces acting on two-dimensional airfoils oscillating at mean incidences below the stall is considered. A method of calculation is suggested which makes use of the steady motion characteristics of the airfoil. At low frequencies, good agreement with the measured aerodynamic derivatives should be obtained as the method is such that it gives the correct values at zero frequency. A comparison between the estimated and measured values of the pitching-moment derivatives for a particular airfoil is made, and this shows that the method suggested gives better agreement with experiment than the usual vortex-sheet theory.

CORRECTIONS TO VELOCITY FOR WALL CONSTRAINT IN ANY 10 x 7 RECTANGULAR SUBSONIC WIND TUNNEL. J. Y. G. Evans. 1953. 42p. diagrs., photos. (ARC R & M 2662; ARC 12,526. Formerly RAE Aero 2307)

The validity and accuracy of methods of determining corrections to the measured velocity in a wind tunnel to compensate for the constraining effect of the walls are reviewed following recent experimental evidence from the R. A. E. 10- by 7-foot subsonic wind tunnel. It is concluded that such corrections, commonly known as "blockage" corrections, can be successfully applied at Mach numbers up to 0.96 but some modifications are necessary to the formulas at present in use. Formulas for the calculation of the longitudinal distribution of blockage increment due to any model, necessary to check the validity of the method in particular cases, are presented in a form which, it is hoped, will facilitate their use in any 10 by 7 wind tunnel. Formulas for the corresponding wall velocity increments, used to check the accuracy of the method by comparison with measured wall pressures, are also given.

SOME HIGH-SPEED TESTS ON TURBINE CASCADES. E. A. Bridle. 1953. 14p. diagrs., photos. (ARC R & M 2697; ARC 12,455. Formerly NGTE R. 48)

High-speed wind-tunnel tests on seven cascades of turbine blades are described, the blades having conventional sections including both reaction and impulse designs. The two-dimensional performance over wide ranges of incidence at Mach numbers up to 1.0 is discussed, special importance being attached to the effects of compressibility. It is shown that the effect of increasing the degree of reaction is to reduce the total-head loss and to increase the unstalled incidence range. High Mach numbers alone are not found to cause a catastrophic increase in loss with these particular blade designs, while the $\cos^{-1}$ throat/pitch rule is found to be approximately true only at high Mach numbers.

THE IMPROVEMENT IN PRESSURE RECOVERY IN SUPERSONIC WIND TUNNELS. H. Eggink. 1953. 18p. diagrs., photos. (ARC R & M 2703; ARC 12,527. Formerly RAE Aero 2326; SD 34)

The inefficient pressure recovery of present-day supersonic wind tunnels, which leads to high costs of plant installation and operation, is discussed and methods of improvement suggested. In particular, the diffuser system, where most of the losses occur, is studied in detail; the improvement to be expected in the pressure recovery by the use of convergent-divergent types is explained and methods of overcoming the necessity for high starting powers with this arrangement are presented. Diffuser experiments based on recent investigations into breakaway phenomena in supersonic flow are described which result in a considerable improvement of pressure recovery. A deceleration from $M = 2.48$ at the working section to $M = 1.42$ at the diffuser throat was obtained using a variable diffuser throat.

THE DESIGN AND TESTING OF SUPERSONIC NOZZLES. R. Harrop, P. I. F. Bright, J. Salmon and M. T. Caiger. 1953. 40p. diagrs., photos., 7 tabs. (ARC R & M 2712; ARC 12,114; ARC 13,383. Formerly RAE Aero 2293; RAE Aero 2293a)

The theory of the flow through a throat near sonic velocity is developed, and is followed by a discussion of the conventional method of designing supersonic nozzles using the method of characteristics. A method of improving the Mach number distribution of the nozzle using the experimental results is developed. The nozzles designed were tested in a 3-inch square wind tunnel in which the Mach number distribution was obtained by shaping the top wall of the working section. The Mach number distribution along the bottom wall was determined from the pressures measured by a series of static-pressure holes along the wall. Considerable difficulty was found in improving the distribution; this was considered to be due to the discontinuity in curvature at the point of inflexion and the influence on the boundary layer of the sudden relaxation of the pressure gradient along the wall. An alternative method of design was developed which avoided this discontinuity in curvature, and considerably better results were obtained when attempts were made to improve the experimental Mach number distribution.

ELASTICITY OF A SHEET REINFORCED BY STRINGERS AND SKEW RIBS, WITH APPLICATIONS TO SWEPT WINGS. E. H. Mansfield. 1953. 27p. diagrs. (ARC R & M 2758; ARC 12,990. Formerly RAE Structures 52)

A rigorous theory has been developed for determining the stresses and displacements in a sheet reinforced by stringers and ribs which are not at right angles to the stringers. The solution of many problems of practical importance has been facilitated by the introduction of a stress function. The theory has been applied to a cylinder of rectangular section stiffened with such skew ribs (a simplified representation of a swept wing). It is shown that there are axes about which applied moments produce pure twist or pure curvature of the cylinder. There are simple formulas for determining these axes and the relationships between twist and curvature and the applied moments.

POLYMETHYL METHACRYLATE (PERSPEX TYPE) PLASTICS; CRAZING, THERMAL AND MECHANICAL PROPERTIES. H. Warburton Hall and E. W. Russell. 1953. 27p. diagrs., photos., 2 tabs. (ARC R & M 2764; ARC 12,829. Formerly RAE Chem. 454)

The report summarizes the more practical aspects of the results of a long-term investigation of the basic physical and chemical properties of polymethyl methacrylate ("Perspex" type) plastic. Thermal, elastic, crazing, solvent absorption, and mechanical properties are included and the effect of these on the service efficiency of a plastic structure is described. Experimental evidence is given concerning the essential role of tensile stress and absorbed solvent in causing crazing and recommendations concerning means to reduce or avoid the incidence of crazing are included. The basic thermal properties are compared with those of metals and the dangers of differential expansion in combined metal-plastic structures are noted, together with the serious effects of chilling of plastic structures during the "hot-forming" operation. Details are given of appropriate heat treatments designed to remove casting and workshop strains without causing distortion.

SOME PRELIMINARY MODEL EXPERIMENTS ON THE WHIRLING OF SHAFTS. E. Downham. 1953. 20p. diagrs., photos. (ARC R & M 2768; ARC 13,733. Formerly RAE Structures 82)

Experimental work is now being done to establish a basis for the solution of whirling problems on turbine and contrarotating shaft systems in the design stage. This report is concerned primarily with the degree of accuracy to be expected from experiments on models. In experiments here described results are obtained for a simple cantilever system which are in close agreement with theory. With more complicated systems the error is somewhat greater owing to practical effects not covered by theory, though still acceptable for most design purposes.

FLOW PATTERNS IN THE WAKE OF AN OSCILLATING AEROFOIL. J. B. Bratt. 1953. 27p. diagrs., photos. (ARC R & M 2773. Formerly ARC 13,001; FM 1423; 0.864)

Part I of the report gives an account of experiments made with the National Physical Laboratory smoke generator to obtain smoke patterns in the wake of an airfoil performing a rolling oscillation in a wind stream. Calculations are given in part II relating to the smoke patterns produced by a nozzle in uniform motion relative to (a) an infinite row of equally spaced two-dimensional discrete vortices of alternate sign and (b) an infinite two-dimensional vortex sheet with sinusoidal distribution of strength. Comparison with certain of the smoke patterns discussed in part I suggests that the wake vorticity can be treated very closely as a system of discrete vortices, and this is supported by the consideration that the elements of a continuous vortex sheet would in general be subject to normal induced velocities, which would tend to break the sheet up. The tendency for this to occur would be greater for the higher values of ω, wince the variation of vorticity with distance along the wake would be greater. The induced velocities for a uniform infinite vortex sheet would be zero.

THE BUCKLING IN COMPRESSION OF PANELS WITH SQUARE TOP-HAT SECTION STRINGERS. W. S. Hemp and K. H. Griffin. 1953. 14p. diagrs., tab. (ARC R & M 2635; ARC 12,462. Formerly College of Aeronautics, Cranfield, Rept. 29)

A simplified panel model is described, together with a number of assumptions about the mode of its buckling. The approach to the calculation of the buckling stress is by splitting the panel into a number of flat plates and treating these by the ordinary plate theory. Use of the boundary conditions between these plates leads to a relation between the buckling stress and the variables of the panel geometry. The results thus obtained are compared with two sets of recent experimental work, and an appendix is included to show the effect of initial panel irregularities on the experimental determination of buckling stresses.

INVESTIGATION OF SKIN BUCKLING. D. J. Farrar. 1953. 62p. diagrs., 12 tabs. (ARC R & M 2652; ARC 11,036; ARC 11,037; ARC 11,038. Formerly MOS S & TM 12A/47; S & TM 12B/47; S & TM 12C/47; Bristol Aeroplane Co., Ltd. CR 434)

The present tests were conducted on aluminum alloy plates in endwise compression, with varying conditions of edge support, to provide data on the buckling stress and post-buckling behavior of aircraft skins. All the plates tested were 35 inches long and nominally 0.064 inch thick. The plate width between the supports was varied between 35 and 120 times its thickness. Both clad (D.T.D. 546) and unclad (D.T.D. 646) material were tested. Three types of edge support were used: rows of steel balls in vee-grooved blocks, intended to imitate pin-edged conditions; rows of steel rollers in recessed blocks, intended to imitate clamp-edged conditions; and a single type of stringer used in previous panel tests. Measurements were made of the plate load and mean strain, and of the shape of the skin buckles. The test technique is discussed and the experimental results compared with theory.

WIND-TUNNEL TESTS ON A 12-FT DIAMETER HELICOPTER ROTOR. H. B. Squire, R. A. Fail and R. C. W. Eyre. 1953. 19p. diagrs., photos., 5 tabs. (ARC R & M 2695; ARC 12,524. Formerly RAE Aero 2324)

Measurements of the thrust, torque, and flapping angle for a 12-foot diameter rotor over a range of blade angle, shaft inclination, and tip-speed ratio have been made to give information on the validity of the standard rotor theory and of the effect of stalling on the retreating blade. Good agreement with the theory was obtained over the normal operating range, using airfoil characteristics determined from the measurements in the static thrust condition. Stalling was found to be progressive in character showing first by an increase in torque and flapping angle and later by a fall in thrust, as compared with the calculated values.

SOME RELATED OSCILLATION PROBLEMS. W. J. Duncan. 1953. 12p. diagrs. (ARC R & M 2707; ARC 12,406. Formerly College of Aeronautics, Cranfield, Rept. 27)

Two simple means for establishing a relation between a pair of oscillation problems are briefly discussed. In the first, the displacements are connected by use of a differential operator. The set of natural frequencies is identical for the two problems and results of interest are obtained when the transformed boundary conditions can be physically interpreted. In this manner, it is shown, for example, that a flywheel on a uniform shaft can be transformed into a flexible coupling and a mass carried on a uniform beam into a flexible hinge. In the second, the connection is established by use of the concept of mechanical admittance. Here the frequency equations are simply related but the frequencies are not.

VELOCITY DISTRIBUTION ON UNTAPERED SHEARED AND SWEPT-BACK WINGS OF SMALL THICKNESS AND FINITE ASPECT RATIO AT ZERO INCIDENCE. S. Neumark and J. Collingbourne. 1953. 50p. diagrs. (ARC R & M 2717; ARC 12,491. Formerly RAE Aero 2316)

This report is a continuation of an earlier one and puts forward several new solutions of the problems of velocity distribution on finite or semi-infinite untapered wings, at zero incidence. The solutions are based on the first order method of sources and sinks, which is shown to be sufficiently accurate to deal with problems involving tips or kinks. The fundamental case considered is that of a semi-infinite sheared wing, and the theory is built up to embrace finite sheared and sweptback wings, straight wings being dealt with as special cases. Complete detailed solutions are given for wings with biconvex parabolic profile, and the problems involving arbitrary profiles are investigated in a more general way. The velocity distribution in the regions of kinks and tips differing considerably from that on an infinite sheared wing, some local positive or negative drag arises in these regions.

The drag distribution is calculated for the case of a biconvex parabolic profile, and it is found that, while the total resultant drag must obviously be nil for a finite wing, it may differ from zero for infinite or semi-infinite wings. This "potential" drag is generally small.

SCHLIEREN TESTS ON SOME CONVENTIONAL TURBINE CASCADES. J. A. Dunsby. 1953. 14p. diagrs., photos. (ARC R & M 2728; ARC 12,893. Formerly NGTE R. 56)

Schlieren tests on a series of conventional turbine cascades have shown that the variations in performance at high speed can be accounted for by shock-wave and boundary-layer interaction. The rise in loss coefficient sometimes encountered at outlet Mach numbers of 0.6 to 0.8 is shown to be due to the formation of a λ shock series on the upper surface of the blade, the subsequent fall in loss coefficient and increase in deflection as the outlet Mach number rises to unity being caused by the formation of a shock system at outlet which forces the separated part of the boundary layer back on to the blade surface. It is shown that a λ shock series may form on a boundary layer which is apparently turbulent. This has not been observed before.

STRESSES IN BUILT-UP BEAMS DUE TO AN ABRUPT CHANGE IN SHEAR STRESS AT A LOADING STATION. J. Taylor. 1953. 18p. diagrs., photos. (ARC R & M 2775; ARC 12,737. Formerly RAE Structures 48)

Owing to the abrupt change in shear stress at loading sections of beams there is a concentration of direct stress in the outer fibers of the beam near the loading section. A method of calculating this concentration is described. The highest stress concentrations occur in short deep beams and are greater for wooden than metal beams. The method is applied to the spars of two wooden aircraft and stress concentrations 1.06 and 1.4 are found at the fuselage attachments. Strain measurements were made at positions on a wooden beam under load and the theoretical predictions verified.

THE EVALUATION OF DOWNWASH AT LARGE SPANWISE DISTANCES FROM A VORTEX LATTICE. H. C. Garner. 1953. 8p. diagrs., 6 tabs. (ARC R & M 2808. Formerly ARC 13,624; Perf. 727; S & C 2472)

This note explains an improved numerical method of evaluating the contributions to the downwash at moderate or large spanwise distances from a vortex lattice. By allowing freedom of choice of the chordwise positions of the discrete vortices of the lattice, it is possible to select three definite chordwise positions and strengths of vortices at each of these positions dependent on the chordwise pressure distribution, so as to determine the downwash with good accuracy for three particular pressure distributions proportional to $\cot \frac{1}{2}\theta$, $\sin \theta$, and $\sin 2\theta$. The corresponding chordwise loading factors have also been evaluated for deflected flaps.

GROWTH OF THE TURBULENT WAKE CLOSE BEHIND AN AEROFOIL AT INCIDENCE. D. A. Spence. 1953. 18p. diagrs. (ARC CP 125)

Knowledge of the variation close behind a trailing edge of the wake displacement thickness $\delta^* = \int \left(1 - \frac{u}{U}\right) dy$ is necessary in calculations of the circulation round an airfoil. Examination of data now available reveals that in the wake: (1) velocity profiles on either side of the line of minimum velocity may be derived from the corresponding trailing-edge boundary-layer profiles by change of scale of each coordinate; (2) the velocity defect at corresponding points follows a universal recovery law of the form $K(x - x_0)^{-\frac{1}{2}}$ even close to the trailing edge. An immediate consequence of these two empirical properties is a simple relation for the form parameter $H = \delta^*/\theta$ at points in the wake in terms of trailing-edge values. In conjunction with the momentum equation, this makes δ^* determinate. Agreement with experiment is very satisfactory.

NOTE ON THE LIFT SLOPE, AND SOME OTHER PROPERTIES, OF DELTA AND SWEPT-BACK WINGS. E. F. Relf. 1953. 9p. diagrs., tab. (ARC CP 127)

In studying and comparing various theories for the determination of the distribution of loading on wings, Garner has given values for the lift slope of several families of sweptback and delta wings deduced from several different lifting-surface theories. In figure 8 of reference 1, Garner has plotted these lift slopes as functions of the aspect ratio A, for different values of the angle of sweep. It occurred to the writer to try plotting the ratio of the lift slope to that for elliptic loading instead of the lift slope itself, and when this was done it was noticed that the above ratio was very nearly independent of aspect ratio A, and gave a unique curve for all the available results when plotted against sweepback angle A. It has been possible to make some comparisons of theoretical deductions drawn from the above with measurements made in the C. A. T. on four delta wings, one swept wing, a tapered swept wing on a body, and two untapered swept wings on a body at high Reynolds numbers, where one could expect a close approximation to potential theory. While analyzing the C. A. T. results, values of the quantity K in the formula $C_D = C_{D_0} - \frac{K}{\pi A} C_L^2$ were collected and studied. Lastly, a study was made of scale effects in the C. A. T. tests.

CURRENT NACA REPORTS

NACA Rept. 1099

AIR FORCES AND MOMENTS ON TRIANGULAR AND RELATED WINGS WITH SUBSONIC LEADING EDGES OSCILLATING IN SUPERSONIC POTENTIAL FLOW. Charles E. Watkins and Julian H. Berman. 1952. ii, 25p. diagrs., tab. (NACA Rept. 1099. Formerly TN 2457)

This analysis treats the air forces and moments in supersonic potential flow on oscillating triangular wings and a series of sweptback and arrow wings with subsonic leading edges and supersonic trailing edges. The linearized velocity potential for the wings undergoing sinusoidal torsional oscillations simultaneously with vertical translations is derived in the form of a power series in terms of a frequency parameter. Although as many terms of such a series expansion as may be desired can be determined, the terms after the first few become very cumbersome. Closed expressions that include the reduced frequency to the third power, an order which is sufficient for a large class of practical applications, are given for the velocity potential and components of chordwise section force and moment coefficients.

NACA Rept. 1103

GENERALIZED THEORY FOR SEAPLANE IMPACT. Benjamin Milwitzky. 1952. iii, 75p. diagrs., 4 tabs. (NACA Rept. 1103)

The motions, hydrodynamic loads, and pitching moments experienced in impacts of V-bottom seaplanes are analyzed and compared with experiment. The analysis is presented in terms of generalized variables which are related through a single parameter, called the approach parameter κ. For use in the design of seaplanes, charts are presented showing the generalized relationships which apply throughout the impact; charts are also presented which show the variations with κ of the generalized variables at the instants of maximum acceleration, maximum pitching moment about the step, maximum penetration, and exit during rebound. The effects of chine immersion on the maximum load are also determined. Extensive experimental data are presented to permit evaluation of the theoretical results.

NACA Rept. 1118

METHOD FOR CALCULATION OF LAMINAR HEAT TRANSFER IN AIR FLOW AROUND CYLINDERS OF ARBITRARY CROSS SECTION (INCLUDING LARGE TEMPERATURE DIFFERENCES AND TRANSPIRATION COOLING). E. R. G. Eckert and John N. B. Livingood. 1953. ii, 29p. diagrs. (NACA Rept. 1118. Formerly TN 2733)

A method which permits approximation of local heat-transfer coefficients in the laminar-flow region around cylinders of arbitrary cross section from those for wedge-type profiles is extended to include the effects of large temperature differences and transpiration cooling. Charts prepared from exact solutions of the laminar boundary-layer equations for wedge-type profiles which allow for these effects yield results with a minimum of calculation. Application of the method to circular and elliptic transpiration cooled cylinders is made to determine local heat-transfer coefficients and surface temperatures and to determine the variation in coolant flow required for maintaining a constant surface temperature.

NACA Rept. 1119

RECIPROCITY RELATIONS IN AERODYNAMICS. Max. A. Heaslet and John R. Spreiter. 1953. ii, 16p. diagrs. (NACA Rept. 1119. Formerly TN 2700)

Reserve-flow theorems in aerodynamics are shown to be based on the same general concepts involved in many reciprocity theorems in the physical sciences. Reciprocal theorems for both steady and unsteady motion are found as a logical consequence of this approach. No restrictions on wing plan form or flight Mach number are made beyond those required in linearized compressible-flow analysis. A number of examples are listed, including general integral theorems for lifting, rolling, and pitching wings and for wings in nonuniform downwash fields. Correspondence is also established between the build-up of circulation with time of a wing starting impulsively from rest and the build-up of lift of the same wing moving in the reverse direction into a sharp-edge gust.

NACA TN 3030

A METHOD FOR CALCULATING THE SUBSONIC STEADY-STATE LOADING ON AN AIRPLANE WITH A WING OF ARBITRARY PLAN FORM AND STIFFNESS. W. L. Gray and K. M. Schenk, Boeing Airplane Company. December 1953. ii, 120p. diagrs., tab. (NACA TN 3030)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A method for computing the span load distribution on an elastic airplane wing at specified airplane weights and load factors is given. The method which applies for subcritical Mach numbers for wings of arbitrary plan form and stiffness distribution includes the effects of external stores and fuselage on the spanwise loading. Modifications are outlined for treating tail-boom and tailless airplane configurations and for calculating the divergence dynamic pressure of a swept wing with a large external store. A method is also outlined for reducing wind-tunnel data to obtain effective aerodynamic coefficients which are Mach number can readily be evaluated from the aerodynamic coefficients thus obtained.

NACA TN 3054

INVESTIGATION AT SUPERSONIC SPEEDS OF THE WAVE DRAG OF SEVEN BOATTAIL BODIES OF REVOLUTION DESIGNED FOR MINIMUM WAVE DRAG. August F. Bromm, Jr. and Julia M. Goodwin. December 1953. 14p. diagrs., photo. (NACA TN 3054)

Results are presented from an investigation of the variation with Reynolds number and Mach number of the wave drag of seven boattail bodies of revolution designed for minimum wave drag according to the theory presented in NACA TN 2550.

NACA TN 3057

A SIMPLIFIED MATHEMATICAL MODEL FOR CALCULATING AERODYNAMIC LOADING AND DOWNWASH FOR WING-FUSELAGE COMBINATIONS WITH WINGS OF ARBITRARY PLAN FORM. Martin Zlotnick and Samuel W. Robinson, Jr. January 1954. 38p. diagrs. (NACA TN 3057. Formerly RM L52J27a)

For the purpose of calculating the aerodynamic loading on the fuselage, the midwing wing-fuselage combination with a fuselage of circular cross section can be represented by a simple system of horseshoe vortices located on the wing with images located inside the fuselage. By using this simplified mathematical model or the extension of it given in an appendix for nonmidwing configurations with fuselages of arbitrary cross section, a method for calculating the lift and longitudinal center of pressure on the fuselage in the presence of the wing at subsonic speeds is presented. In addition the report shows how the simplified mathematical model can be used for calculating the downwash behind the wing and for calculating the spanwise lift distribution on the wing for midwing configurations with axisymmetric fuselages.

NACA TN 3060

USE OF ELECTRIC ANALOGS FOR CALCULATION OF TEMPERATURE DISTRIBUTION OF COOLED TURBINE BLADES. Herman H. Ellerbrock, Jr., Eugene F. Schum and Alfred J. Nachtigall. December 1953. 116p. diagrs., photos., 6 tabs. (NACA TN 3060)

An investigation was conducted to develop simple, inexpensive electric analogs for determining temperatures of cooled turbine blades. The accuracy of such analogs was determined by fabricating three for specific blade configurations and comparing values of blade temperatures obtained with them with calculated values of blade temperature when air-cooled blades were considered and by relaxing the analog values for liquid-cooled blades to determine whether the residuals were acceptable. In general, good agreement was achieved between calculated and analog values of blade temperature.

NACA TN 3061

STRESSES AROUND RECTANGULAR CUTOUTS IN TORSION BOXES. Paul Kuhn and James P. Peterson. December 1953. 71p. diagrs., 2 tabs. (NACA TN 3061)

A method is presented for calculating the stresses produced by rectangular cutouts of any size in torsion boxes. The problem is divided into a "box problem" and a "cover problem." The box problem is a special case of the general method of analyzing torsion boxes without cutouts. In the cover problem, simple shear-lag theory is used to obtain "key" stresses; the final distributions are obtained from these key stresses by means of simple rules or empirical distribution curves. Comparisons with the results from three series of tests in which the dimensions of the cutouts varied over a wide range are shown.

NACA TN 3088

DETERMINATION OF THE FLYING QUALITIES OF THE DOUGLAS DC-3 AIRPLANE. Arthur Assadourian and John A. Harper. December 1953. 67p. diagrs., photos., tab. (NACA TN 3088)

Data are presented showing the longitudinal and lateral stability and control characteristics and the stalling behavior of the Douglas DC-3 airplane and the compliance of these flying qualities with the current Air Force-Navy specifications. Even though the DC-3 was designed and built more than two decades ago, the airplane satisfied most of the current specifications for its type. However, the airplane had static longitudinal instability for certain conditions of airspeed and center-of-gravity position in the power-on configurations, the specified maximum elevator control-force gradient in maneuvers was exceeded in most cases, the rudder forces required to overcome the adverse aileron yaw were excessive and the rudder and aileron forces in steady sideslips fended to lighten at the higher sideslip angles. Typical frequency-response characteristics of the airplane are also presented for those interested in automatic stabilization.

NACA TN 3091

FLOW PROPERTIES OF STRONG SHOCK WAVES IN XENON GAS AS DETERMINED FOR THERMAL EQUILIBRIUM CONDITIONS. Alexander P. Sabol. December 1953. 29p. diagrs., photos., 2 tabs. (NACA TN 3091)

The results of calculations are presented for the purpose of showing the effects of ionization and electronic excitation on the flow properties of one dimensional shock waves in xenon gas. The calculations use statistical-mechanics theory with the assumption that thermal equilibrium exists at all points in the flow. The calculations are made by both including and neglecting the effects of electronic excitation, and the results of the calculations are qualitatively compared with available experimental data.

NACA TN 3092

HYDRODYNAMIC DRAG OF 12- AND 21-PERCENT-THICK SURFACE-PIERCING STRUTS. Claude W. Coffee, Jr. and Robert E. McKann. December 1953. 28p. diagrs., photos., tab. (NACA TN 3092)

An investigation has been made to determine the hydrodynamic drag of three surface-piercing untapered struts at approximately 0° angle of yaw at depths up to 6 chords for speeds up to 80 fps at various angles of rake. Two struts had NACA 66_1-012 airfoil sections, one with a 4-inch chord and the other with an 8-inch chord. The third strut had an NACA 66_4-021 airfoil section and a 4-inch chord.

NACA TN 3094

THE RESISTANCE TO AIR FLOW OF POROUS MATERIALS SUITABLE FOR BOUNDARY-LAYER-CONTROL APPLICATIONS USING AREA SUCTION. Robert E. Dannenberg, James A. Weiberg and Bruno J. Gambucci. January 1954. 21p. diagrs., photos., tab. (NACA TN 3094)

Measurements have been made of resistance to air flow of commercially available porous materials. Three general types of porous media were tested - granular (sintered metals), fibrous (felt cloths and filter papers), and perforated. The flow-resistance characteristics were ascertained over a wide range of differential pressures across the material. The flow resistance of one of the materials was determined for various values of air pressure at the upstream face of the material.

NACA TN 3114

ANALYSIS OF MULTICELL DELTA WINGS ON CAL-TECH ANALOG COMPUTER. Richard H. MacNeal and Stanley U. Benscoter, California Institute of Technology. December 1953. 84p. diagrs., 6 tabs. (NACA TN 3114)

Using the Cal-Tech analog computer, structural analyses have been made of two delta wings with 45° leading edges. One of these has a constant-depth rectangular cross section and the other has a biconvex cross section that is linearly tapered in the spanwise direction. The wings extend through the fuselage and are rigidly supported along two lines at the faces of the fuselage. Deflections and all internal forces have been calculated for concentrated static loads. Vibration modes are also presented. The effects of neglecting shearing strains in the ribs and spars and also of assuming the ribs to be rigid have been investigated by modifying the electric circuits to correspond to these simplifications.

NACA RM E53I29

EFFECTS OF ADDITIVES ON PRESSURE LIMITS OF FLAME PROPAGATION OF PROPANE-AIR MIXTURES. Frank E. Belles and Dorothy M. Simon. December 1953. 36p. diagrs., tab. (NACA RM E53I29)

Seven additives in 0.5-volume-percent concentration were studied for their effects on the low-pressure limits of flame propagation of propane-air mixtures. The limits were measured in a flame tube of new design. Mixtures containing approximately 2 to 8 percent propane by volume were studied. The limit curves were without lobes on the rich side and were closely related to quenching-distance data measured by the flash-back of a Bunsen flame. The data were analyzed by means of the experimental curves and the Le Chatelier law governing the flammability limits of mixed fuels. Ethyl nitrate and chloropicrin were found to be definite promoters of flame propagation in rich mixtures. Chloropicrin and methyl bromide inhibited propagation in lean mixtures; it was concluded that the effect is chemical and that these additives do not act merely as inert gases. None of the additives promoted flame propagation in lean mixtures more than could be explained by the contribution of the additive to the total fuel in the mixture. Methyl bromide increased the minimum pressure for flame propagation and was the only additive that had an appreciable effect on the minimum. Carbon disulfide had a large inhibitory effect on flame propagation in lean mixtures, as defined by deviations from the requirements of Le Chatelier's law.

Royal Aircraft Establishment (Gt. Brit.)
STRENGTH DATA ON CIRCULAR METAL CYLINDERS UNDER AXIAL COMPRESSION. J. H. Shelley. August 1953. 87p. diagrs., photos., 3 tabs. (RAE Tech. Note Structures 122)

Failure of circular metal cylinders under axial compression is examined empirically for the practical range of the wall thickness/radius ratio. The cylinders considered are those of length such that end conditions do not have an appreciable effect upon

failure, but not long enough to fail as Euler struts. The paper is based on experimental results given in 15 separate publications, and covers wide ranges of material specifications, manufacturing methods, testing procedures, and specimen sizes. The design proposals submitted use as far as practicable the formulas suggested by other authors, and are compared with the experimental results obtained for 381 steel and 143 aluminum alloy specimens over the full range of t/R.

Advisory Group for Aeronautical Research and Development. SPECIFICATIONS FOR AGARD WIND TUNNEL CALIBRATION MODELS. (Presented at Rome AGARD conference, December 16-17, 1952) 4p. diagrs. (Advisory Group for Aeronautical Research and Development. AG4/M3)

Two standard wind-tunnel models accepted by the AGARD are described. One is the NACA RM-10 on which considerable data are available immediately. The RM-10 is designated as AGARD calibration model A. The other, AGARD calibration model B, is a new configuration consisting of a body-wing combination. The wing is a delta wing with a span four times the body diameter. The wing consists of an equilateral triangle with a symmetrical circular-arc section. The body is a body of revolution.

DECLASSIFIED NACA REPORTS

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM RESTRICTED TO UNCLASSIFIED, 12/11/53.

NACA RM 51B05

PROPERTIES OF LOW-CARBON N-155 ALLOY BAR STOCK FROM 1200° TO 1800° F. J. W. Freeman and A. E. White, University of Michigan. May 3, 1951. 103p. diagrs., photos., 21 tabs. (NACA RM 51B05)

Results are presented of an investigation undertaken to establish rupture and total-deformation strengths ("design" data) at 1200° to 1800° F for typical commercial treatments of low-carbon N-155 alloy. Rupture data are given for bar stock from two heats at 1200°, 1350°, and 1500° F and for one of the heats at 1650° and 1800° F in several conditions of prior treatment. Because the variation between heats indicated that the data would be of questionable value as typical design data, the work was stopped with data on stress and time for total deformation somewhat incomplete and with very little duplication between the two heats.

NACA RM 51D20

REVIEW OF CURRENT AND ANTICIPATED LUBRICANT PROBLEMS IN TURBOJET ENGINES. NACA Subcommittee on Lubrication and Wear. Appendix A: THE DEVELOPMENT OF LUBRICANTS FOR EXTREME TEMPERATURE OPERATIONS FOR CURRENT AND PROJECTED TURBINE-POWERED AIRCRAFT ENGINES. C. M. Murphy and W. A. Zisman. Appendix B: AIRCRAFT TURBINE LUBRICANTS FOR MILITARY USE. C. C. Singleterry. Appendix C: BEARING PROBLEMS IN CURRENT AND PROJECTED TURBO POWER PLANT. C. J. McDowall. Appendix D: INVESTIGATIONS OF ROLLING BEARINGS AT SKF INDUSTRIES, INC. H. Styri. Appendix E: LUBRICANTS FOR OPERATION OF AIRCRAFT GAS TURBINE ENGINES OVER WIDE TEMPERATURE RANGES. NACA Lewis Flight Propulsion Laboratory Staff. April 20, 1951. 46p. diagrs., 4 tabs. (NACA RM 51D20)

Present and future lubricants for aircraft gas-turbine engines using rolling contact bearings must meet operating requirements of fludity, lubricity, volatility, and stability over bearing operating temperature regions of (1) -65° to 350° F (current), (2) -65° to 500° F, and (3) -65° to 750° F. The most promising lubricants for these temperature ranges involve the use of synthetics (that is, aliphatic diesters) in whole or in part.

NACA RM 53B19

WEIGHT BAR CHARTS. B. J. Saelman and H. W. Vick, Lockheed Aircraft Corporation. June 1953. 62p. diagrs., tab. (NACA RM 53B19)

The weight breakdowns in bar chart form in the present report have been prepared to give an indication of "how we spend our weight." They are expected to focus attention on the design functions that warrant weight reduction activity on future models.

NACA RM A50A04a

CHORDWISE AND SPANWISE LOADINGS MEASURED AT LOW SPEEDS ON A LARGE TRIANGULAR WING HAVING AN ASPECT RATIO OF 2 AND A THIN, SUBSONIC-TYPE AIRFOIL SECTION. David Graham. March 13, 1950. 55p. diagrs., photo., 2 tabs. (NACA RM A50A04a)

Pressure data have been obtained on a large triangular wing having an aspect ratio of 2 and a modified NACA 0005 section. The data were obtained at zero angle of sideslip through an angle-of-attack range from zero lift through the stall with three deflections of a trailing-edge flap. Chordwise pressure distributions, section lift characteristics, section centers of pressure, and span load distribution are presented. The tests were conducted at a dynamic pressure of 25 pounds per square foot resulting in a Reynolds number, based on the mean aerodynamic chord, of 15.3×10^6. The Mach number was 0.13.

NACA RM A50A10

EFFECTS OF TWIST AND CAMBER ON THE LOW-SPEED CHARACTERISTICS OF A LARGE-SCALE 45° SWEPT-BACK WING. Lynn W. Hunton. March 20, 1950. 32p. diagrs., photos., tab. (NACA RM A50A10)

Tests were made of a large-scale, semispan, swept-back, wing-fuselage model cambered and twisted for an ideal lift coefficient of 0.4 and of a similar model but having no camber and no twist. The 0.25 chord lines of the wings were swept back 45° and the wings had an aspect ratio of 6.0 and a taper ratio of 0.5. The aerodynamic characteristics, span loading, and tuft-study results for the models are presented for a Reynolds number of 8 million at a Mach number of 0.2. Predicted results from available theoretical methods are compared with the experimental data.

NACA RM A50B13

PRESSURE COEFFICIENTS AT MACH NUMBERS FROM 0.60 TO 0.85 FOR A SEMISPAN WING WITH NACA 0012-64 SECTION, 20-PERCENT-CHORD PLAIN AILERON, AND 0° AND 45° SWEEPBACK. Walter J. Krumm. April 19, 1950. 36p. diagrs., 30 tabs. (NACA RM A50B13)

The pressure measurements obtained during tests of a semispan wing having the NACA 0012-64 section are presented as coefficients. The measurements were made at Mach numbers from 0.60 to 0.85 for the wing with 0° and with 45° sweepback and with a 20-percent-chord, plain, trailing-edge aileron.

NACA RM A50E09

THE EFFECTS OF COMPRESSIBILITY ON THE PRESSURES ON A BODY OF REVOLUTION AND ON THE AERODYNAMIC CHARACTERISTICS OF A WING-NACELLE COMBINATION CONSISTING OF THE BODY OF REVOLUTION MOUNTED ON A SWEPT-BACK WING. Frederick W. Boltz and Benjamin H. Beam. July 26, 1950. 68p. diagrs., photos., 2 tabs. (NACA RM A50E09)

Results of wind-tunnel tests are presented for a semispan model of a wing-nacelle combination and for an isolated body of revolution similar to the nacelle. The wing had the leading edge swept back 37.25°, an aspect ratio of 6.04, a taper ratio of 0.5, zero twist, and NACA 64_1-212 sections. The simulated nacelle and the body of revolution each had a fineness ratio of 6.5. Lift, drag, pitching-moment, and pressure data for the wing-nacelle combination were obtained for Mach numbers from 0.18 to 0.92 at a Reynolds number of 2,000,000. Drag and pressure data were obtained for the isolated body of revolution for Mach numbers from 0.18 to 0.95 at a Reynolds number of 3,700,000.

NACA RM A50H17

HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A LATERAL-CONTROL MODEL. III - SECTION CHARACTERISTICS, FENCE STUDIES, AND TABULATED PRESSURE COEFFICIENTS WITH MODIFIED NACA 0012-64 SECTION, 26.6-PERCENT-CHORD, PLAIN AILERON, 0° AND 45° SWEEPBACK. Walter J. Krumm and Joseph W. Cleary. November 22, 1950. 79p. diagrs., photos., 4 tabs. (NACA RM A50H17)

The spanwise variations of section normal-force and pitching-moment coefficients were determined from wind-tunnel pressure-distribution measurements of a semispan wing with a modified NACA 0012-64 section and a 26.6-percent-chord plain aileron. Tests were made with the wing unswept and swept back 45° for Mach numbers covering the force-divergence range of the unswept wing. The effect of wing fences on the static longitudinal stability of the swept wing was investigated. Wing pressure coefficients are presented in tables.

NACA RM A50H23

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF A JET-ENGINE NACELLE ON THE AERODYNAMIC CHARACTERISTICS OF A 37.25° SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. Frederick W. Boltz and Donald A. Buell. October 24, 1950. 28p. diagrs., photos. (NACA RM A50H23)

This report presents results of wind-tunnel tests of a model of a jet-engine nacelle in combination with a wing having the leading edge swept back 37.25° and an aspect ratio of 6.04. The nacelle was mounted on the lower surface of the wing with the air inlet slightly behind the wing leading edge and normal to the nacelle axis. Lift, drag, pitching moment, and ram-recovery data are presented for Mach numbers from 0.18 to 0.92 at a constant Reynolds number of 2,000,000. Surface pressure data are presented for Mach numbers near that of drag divergence.

NACA RM A50J24

THE EFFECTS OF CAMBER AND TWIST ON THE AERODYNAMIC LOADING AND STALLING CHARACTERISTICS OF A LARGE-SCALE 45° SWEPT-BACK WING. Lynn W. Hunton and Joseph K. Dew. January 24, 1951. 40p. diagrs., photo., tab. (NACA RM A50J24)

Pressure-distribution measurements were obtained on a large-scale, semispan, sweptback, wing fuselage model cambered and twisted for a design lift coefficient of 0.4 and on a similar model having no camber and no twist. The wings had 45° sweepback of the quarter-chord line, an aspect ratio of 6.0, and a taper ratio of 0.5. Pressure distributions are presented from tests made at a Reynolds number of 8 million and a Mach number of 0.2. Stalling characteristics and spanwise distributions of local lift coefficient and local center of pressure are derived from the data. Theoretical span loadings are compared with the experimental results.

NACA RM A50K28a

THE EFFECTS OF INCREASING THE LEADING-EDGE RADIUS AND ADDING FORWARD CAMBER ON THE AERODYNAMIC CHARACTERISTICS OF A WING WITH 35° OF SWEEPBACK. Fred A. Demele and Fred B. Sutton. February 9, 1951. 27p. diagrs., photo., tab. (NACA RM A50K28a)

Presented in this report are results of an investigation of a sweptback wing which was modified by increasing the leading-edge radius and introducing a small amount of camber over the forward portion of the chord. The wing had 35° of sweepback at the quarter-chord line, and an aspect ratio of 4.5. The original wing section was the NACA 64A010 normal to the quarter-chord line. Aerodynamic characteristics are presented for Reynolds numbers from 2,000,000 to 11,000,000 at a Mach number of 0.21 and for Mach numbers from 0.21 to 0.94 at a Reynolds number of 2,000,000. A comparison is made with results of an investigation of the unmodified wing.

NACA RM A51C12a

INFLUENCE OF AIRFOIL TRAILING-EDGE ANGLE AND TRAILING-EDGE-THICKNESS VARIATION ON THE EFFECTIVENESS OF A PLAIN FLAP AT HIGH SUBSONIC MACH NUMBERS. Albert D. Hemenover and Donald J. Graham. May 22, 1951. 103p. diagrs., photos., 5 tabs. (NACA RM A51C12a)

The effects of variation of trailing-edge angle and trailing-edge thickness on the characteristics of a 10-percent-chord thick NACA airfoil section with a 25-percent-chord plain flap are appraised from wind-tunnel tests at Mach numbers from 0.3 to 0.9 and Reynolds numbers varying correspondingly from 1 to 2 million. The airfoil trailing-edge angle was varied from 18° to 6°, and the trailing-edge thickness from zero to the thickness at the flap hinge line.

NACA RM A51D02

INVESTIGATION IN THE AMES 12-FOOT PRESSURE WIND TUNNEL OF A MODEL HORIZONTAL TAIL OF ASPECT RATIO 3 AND TAPER RATIO 0.5 HAVING THE QUARTER-CHORD LINE SWEPT BACK 45°. Carl D. Kolbe and Angelo Bandettini. June 25, 1951. 97p. diagrs., photo., 2 tabs. (NACA RM A51D02)

The airfoil section of the model of a horizontal tail was the NACA 64A010 in planes inclined 45° to the plane of symmetry. The test Reynolds number was varied from 2,000,000 to 18,000,000 at a Mach number of 0.25 and the Mach number was varied from 0.25 to 0.94 at Reynolds numbers of 2,000,000 and 4,000,000. Lift, drag, pitching moment, hinge moment, and the pressure difference across the elevator-nose seal are reported.

NACA RM A51D18

EFFECTS OF DOUBLE-SLOTTED FLAPS AND LEADING-EDGE MODIFICATIONS ON THE LOW-SPEED CHARACTERISTICS OF A LARGE-SCALE 45° SWEPT-BACK WING WITH AND WITHOUT CAMBER AND TWIST. Harry A. James and Joseph K. Dew. July 1951. 37p. diagrs., photo., 3 tabs. (NACA RM A51D18)

Tests were made on two large-scale, semispan, wing-fuselage models swept back 45° (aspect ratio 6.0, taper ratio 0.5) equipped with partial-span, double-slotted flaps and various leading-edge modifications. One wing was cambered and twisted for a design lift coefficient of 0.4; the other wing had no camber and no twist. The lift, drag, and pitching-moment characteristics were determined at a Reynolds number of 8 million. Theoretical predictions of lift increment due to flaps and the lift at which flow separation first occurred are compared with experiment.

NACA RM A51E29

LOW-SPEED CHARACTERISTICS OF A 45° SWEPT WING WITH LEADING-EDGE INLETS. Robert E. Dannenberg. August 1951. 48p. diagrs., photos., tab. (NACA RM A51E29)

Pressure-distribution and wake measurements were made to determine the effect of leading-edge inlets on the low-speed aerodynamic characteristics of a 45° swept wing that completely spanned the wind tunnel. The inlets extended over approximately the central third of the span of the wing and varied in entrance height from 15 to 50 percent of the wing thickness. The section characteristics were obtained for a wide range of angles of attack and inlet-velocity ratios.

NACA RM A51G31

THE FORCES AND PRESSURE DISTRIBUTION AT SUBSONIC SPEEDS ON A PLANE WING HAVING 45° OF SWEEPBACK, AN ASPECT RATIO OF 3, AND A TAPER RATIO OF 0.5. Carl D. Kolbe and Frederick W. Boltz. October 1951. 159p. diagrs., photo., 22 tabs. (NACA RM A51G31)

Lift, drag, pitching-moment, and static-pressure data for a model of a plane wing having an aspect ratio of 3 and a taper ratio of 0.5 are reported. The line joining the quarter-chord points of the airfoil sections was swept back 45°. The airfoil sections were the NACA 64A010 in planes inclined 45° to the plane of symmetry. Data are presented for Reynolds numbers from 4,000,000 to 18,000,000 at a Mach number of 0.25 and for Mach numbers from 0.08 to 0.96 at a Reynolds number of 4,000,000. Also included are data at a Reynolds number of 8,000,000 for Mach numbers of 0.08, 0.25, and 0.60. The investigation included a study of the effect of various seals at the model-turntable juncture on the forces, moments, and pressure distribution on the model. Pressure data at seven spanwise stations on the model are presented in tabular form.

NACA RM A51G31a

SUMMARY OF RESULTS OF A WIND-TUNNEL INVESTIGATION OF NINE RELATED HORIZONTAL TAILS. Jules B. Dods, Jr. and Bruce E. Tinling. October 1951. 105p. diagrs., photos., 2 tabs. (NACA RM A51G31a)

A compilation of data is presented for models of nine related horizontal tails. The majority of the results were obtained at a Mach number of approximately 0.20. Three of the models were tested throughout the subsonic Mach number range to a maximum of 0.94. The Reynolds number range was from 2 to 4 million. The models had aspect ratios from 2 to 6, angles of sweepback from 5.7° to 45°, and had 30-percent-chord, sealed, plain flaps. The lift coefficient, hinge moment coefficient, and pressure coefficients across the elevator nose seal are presented. The effects of sweepback, aspect ratio, and Mach number on the lift and hinge-moment parameters are summarized. Comparisons of the experimental results with theoretical calculations are presented.

NACA RM A52A14a

LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A LARGE-SCALE 60° SWEPT-BACK WING WITH HIGH LIFT DEVICES. Mark W. Kelly. March 1952. 54p. diagrs., photo., 7 tabs. (NACA RM A52A14a)

Tests were made in the Ames 40- by 80-foot wind tunnel of a 60° sweptback wing with fuselage and of the combination with various configurations of double-slotted flaps, split flaps, leading-edge slats, and ailerons. Lift, drag, pitching-moment, and rolling-moment data are presented as well as pressure distribution data over the slat, the wing, and flaps. The tests covered a Reynolds number range from 4.0×10^6 to 10.0×10^6. The use of double-slotted flaps and leading-edge slats extended the linear range of the pitching-moment curve from a lift coefficient of about 0.35 to a lift coefficient of about 0.88.

NACA RM A52B19

LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A LARGE-SCALE 45° SWEPT-BACK WING WITH PARTIAL-SPAN SLATS, DOUBLE-SLOTTED FLAPS, AND AILERONS. Harry A. James. April 1952. 101p. diagrs., photos., 9 tabs. (NACA RM A52B19)

Tests were made in the Ames 40- by 80-foot wind tunnel of a 45° sweptback wing with fuselage in combination with various configurations of double-slotted flaps, leading-edge slats, and ailerons. Lift, drag, pitching-moment, and rolling-moment data are presented as well as pressure-distribution data over the slat, wing, and flaps. The tests covered a Reynolds number range from 2.5×10^6 to 8×10^6. The use of double-slotted flaps and leading-edge slats extended the near linear range of the pitching moment from a lift coefficient of about 0.76 to a lift coefficient of about 1.41.

NACA RM A52D01b

BOUNDARY-LAYER MEASUREMENTS ON SEVERAL POROUS MATERIALS WITH SUCTION APPLIED. George B. McCullough and Bruno J. Gambucci. June 1952. 26p. diagrs., photos., tab. (NACA RM A52D01b)

Boundary-layer velocity profiles were measured on several porous materials for a stream velocity of 165 feet per second with ratios of suction velocity to free-stream velocity from 0 to 0.0182. The measurements were made on the wall of a small wind tunnel in a region of nearly zero pressure gradient and in which transition from laminar to turbulent flow was occurring on the smooth impervious wall. The effects of surface roughness and suction velocity are shown.

NACA RM A52J08

DOWNWASH CHARACTERISTICS AND VORTEX-SHEET SHAPE BEHIND A 63° SWEPT-BACK WING-FUSELAGE COMBINATION AT REYNOLDS NUMBER OF 6.1×10^6. William H. Tolhurst, Jr. December 1952. 45p. diagrs., photo. (NACA RM A52J08)

The downwash characteristics and vortex-sheet shape have been experimentally determined for a 63° sweptback wing of aspect ratio 3.5 with a fuselage and with boundary-layer control on the wing to prevent separation. Downwash-angle contour maps are presented for nine vertical transverse planes located between 0.57 and 2.71 semispans aft of the 0.25 mean aerodynamic chord point for three angles of attack at a Reynolds number of 6.1×10^6. The shape of the vortex sheet is presented for the various survey planes and angles of attack. Theoretical and experimental downwash angles are compared.

NACA RM A53A14

EXPERIMENTAL AND THEORETICAL STUDY OF THE INTERFERENCE AT LOW SPEED BETWEEN SLENDER BODIES AND TRIANGULAR WINGS. Edward J. Hopkins and Hubert C. Carel. May 1953. 40p. diagrs., photos., tab. (NACA RM A53A14)

Measurements of the forces and moments were made at a Mach number of 0.25 for several geometrically similar triangular wings (aspect ratio, 2.0) in the presence of a slender body of revolution and for the wings combined with the body. The ratios of maximum body diameter to wing span were 0.196, 0.259, 0.343, and 0.500. Comparisons are made between the experimental results and results calculated by the method given in NACA RM A51G24 which employs the theories of Weissinger, Multhopp, and Lennertz.

NACA RM E50A04

APPLICATION OF BLADE COOLING TO GAS TURBINES. Herman H. Ellerbrock, Jr. and Louis J. Schafer, Jr. May 31, 1950. 102p. diagrs., photos. (NACA RM E50A04)

A review of current knowledge on turbine-blade cooling and a description of pertinent NACA investigations are presented. The gains, which can be obtained by operating turbojet and turbine-propeller engines at high gas temperatures, are shown. Analyses are presented, which give the performance possibilities of various methods of blade cooling as well as the possibility of using nonstrategic blade materials. Finally, the performance characteristics of cooled turbines and of engines using cooled turbines are briefly discussed.

NACA RM E50A05

PRELIMINARY ANALYSIS OF PROBLEM OF DETERMINING EXPERIMENTAL PERFORMANCE OF AIR-COOLED TURBINE. I - METHODS FOR DETERMINING HEAT-TRANSFER CHARACTERISTICS. Herman H. Ellerbrock, Jr. and Robert R. Ziemer. June 12, 1950. 48p. diagrs. (NACA RM E50A05)

In determining the experimental performance of an air-cooled turbine, the heat-transfer characteristics must be evaluated. The suggested formulas that are required to determine these characteristics are presented. The formulas have a form in which dependent parameters are expressed as unknown functions of independent parameters. Methods of experimenting to determine these functions are suggested. In some cases general heat-transfer discussions that lead to the suggested forms of the formulas are given.

NACA RM E50A06

PRELIMINARY ANALYSIS OF PROBLEM OF DETERMINING EXPERIMENTAL PERFORMANCE OF AIR-COOLED TURBINE. II - METHODS FOR DETERMINING COOLING-AIR-FLOW CHARACTERISTICS. Herman H. Ellerbrock, Jr. June 7, 1950. 20p. diagrs. (NACA RM E50A06)

In the determination of the performance of an air-cooled turbine, the cooling-air-flow characteristics between the root and the tip of the blades must be evaluated. The methods, which must be verified and the unknown functions evaluated, that are expected to permit the determination of pressure, temperature, and velocity through the blade cooling-air passages from specific investigations are presented.

NACA RM E50A31

ALTITUDE-CHAMBER PERFORMANCE OF BRITISH ROLLS-ROYCE NENE II ENGINE. III - 18.00-INCH-DIAMETER JET NOZZLE. Ralph E. Grey, Virginia L. Brightwell and Zelmar Barson. July 10, 1950. 60p. diagrs., 2 tabs. (NACA RM E50A31)

An altitude-chamber investigation of British Rolls-Royce Nene II turbojet engine was conducted over range of altitudes from sea level to 65,000 feet and ram pressure ratios from 1.10 to 3.50, using an 18.00-inch-diameter jet nozzle. The 18.00-inch-diameter jet nozzle gave slightly lower values of net-thrust specific fuel consumption than either the 18.41- or the standard 18.75-inch-diameter jet nozzles at high flight speeds. At low flight speeds, the 18.41-inch-diameter jet nozzle gave the lowest values of net-thrust specific fuel consumption.

NACA RM E50B10

ALTITUDE-CHAMBER PERFORMANCE OF BRITISH ROLLS-ROYCE NENE II ENGINE. IV - EFFECT OF OPERATIONAL VARIABLES ON TEMPERATURE DISTRIBUTION AT COMBUSTION-CHAMBER OUTLETS. Sidney C. Huntley. July 3, 1950. 17p. diagrs., photo. (NACA RM E50B10)

Temperature surveys were made at the combustion-chamber outlets of a British Rolls-Royce Nene II engine. The highest mean nozzle-vane and mean gas temperatures were found to occur at a radius approximately 75 percent of the nozzle-vane length from the inner ring of the nozzle-vane assembly. Variations in engine speed, jet-nozzle area, simulated altitude, and simulated flight speed altered the temperature level but did not materially affect the pattern of radial temperature distribution.

NACA RM E50C15

EFFECTS OF INLET ICING ON PERFORMANCE OF AXIAL-FLOW TURBOJET ENGINE IN NATURAL ICING CONDITIONS. Loren W. Acker and Kenneth S. Kleinknecht. May 25, 1950. 61p. diagrs., photos., tab. (NACA RM E50C15)

A flight investigation in natural icing conditions was conducted to determine the effect of inlet ice formations on the performance of axial-flow turbojet engines. The results are presented for icing conditions ranging from a liquid-water content of 0.1 to 0.9 gram per cubic meter and water-droplet size from 10 to 27 microns at ambient-air temperature from 13° to 26° F. The data show time histories of jet thrust, air flow, tail-pipe temperature, compressor efficiency, and icing parameters for each icing encounter. The effect of inlet-guide-vane icing was isolated and shown to account for approximately one-half the total reduction in performance caused by inlet icing.

NACA RM E50C28

COMPARISON OF OUTSIDE-SURFACE HEAT-TRANSFER COEFFICIENTS FOR CASCADES OF TURBINE BLADES. James E. Hubbartt. July 17, 1950. 30p. diagrs., tab. (NACA RM E50C28)

A comparison of available results from heat-transfer investigations on cascades of turbine blades is presented using the Nusselt equation. The conventional correlation procedure is modified by defining the Reynolds number by the average of the velocities and the pressures around the blades. The correlation of the results from impulse blades was improved by using the Reynolds number defined by the average velocity and pressure. The final comparison indicated that several variables, which possibly influence heat transfer, should be investigated.

NACA RM E50D03a

HEAT-TRANSFER AND OPERATING CHARACTERISTICS OF ALUMINUM FORCED-CONVECTION AND STAINLESS-STEEL NATURAL-CONVECTION WATER-COOLED SINGLE-STAGE TURBINES. John C. Freche and A. J. Diaguila. June 30, 1950. 48p. diagrs.. photo., 2 tabs. (NACA RM E50D03a)

Two water-cooled turbines were operated - one with blades and disk of aluminum alloy cooled by forced convection and the other with blades and disk of stainless steel cooled by natural convection. Heat-transfer data, coolant pumping power, and operational data, such as gas temperatures, coolant-flow rates, and blade temperatures, are presented. The heat-transfer results for both turbines agreed with those for static-cascade and stationary-tube investigations. Coolant pumping losses were not excessive and are further reducible by discharging the coolant at a smaller radius.

NACA RM E50D25

ANALYTICAL INVESTIGATION OF FLOW AND HEAT TRANSFER IN COOLANT PASSAGES OF FREE-CONVECTION LIQUID-COOLED TURBINES. E. R. G. Eckert and Thomas W. Jackson. July 18, 1950. 45p. diagrs. (NACA RM E50D25)

The theoretical aspect of the problem of free-convection liquid cooling of turbine blades was investigated using boundary-layer calculations. A method of improving the heat transfer in a hole with a small diameter-to-length ratio is described. Comparisons of theoretical equations with experimental results for a free-convection water-cooled turbine are made and the effect of Coriolis forces on the cooling effect is discussed.

NACA RM E50D27

PERFORMANCE OF 24-INCH SUPERSONIC AXIAL-FLOW COMPRESSOR IN AIR. III - COMPRESSOR PERFORMANCE WITH INLET GUIDE VANES. Melvin J. Hartmann and Edward R. Tysl. July 10, 1950. 15p. diagrs. (NACA RM E50D27)

The use of inlet guide vanes with the 24-inch supersonic compressor resulted in a decrease in maximum pressure ratio and adiabatic efficiency, and a slight increase in equivalent mass flow. The loss in total pressure and efficiency resulted from reduced diffusion in the rotor-blade passages, increased shock losses at the higher entrance Mach number, and increased boundary-layer thickness, separation, and transfer of mass flow toward the rotor hub. The unsteady flow field created at the compressor entrance by the guide-vane wakes is also responsible for some of the losses. This inherent loss will be encountered whenever inlet guide vanes are used with the shock-in-rotor type of supersonic compressor.

NACA RM E50E03

INVESTIGATION OF AERODYNAMIC AND ICING CHARACTERISTICS OF WATER-INERTIA-SEPARATION INLETS FOR TURBOJET ENGINES. Uwe von Glahn and Robert E. Blatz. July 26, 1950. 54p. diagrs., photos., 3 tabs. (NACA RM E50E03)

Aerodynamic and icing investigations of several internal water-inertia-separation inlets designed to prevent entrance of water into a turbojet engine in an icing condition are presented. Comparisons of total-pressure loss, mass flow, and icing characteristics are made. Complete icing protection of inlet guide vanes was not achieved. Approximately 8 percent of the volume of water entering the inlets remained in the air. For nonicing operation, total-pressure losses were comparable to those of direct-ram inlets. Under icing conditions, considerable total-pressure losses were obtained with inertia-separation inlets.

NACA RM E50E04

NUMERICAL SOLUTION OF EQUATIONS FOR ONE-DIMENSIONAL GAS FLOW IN ROTATING COOLANT PASSAGES. W. Byron Brown and Richard J. Rossbach. June 26, 1950. 119p. diagrs., tabs. (NACA RM E50E04)

In order to analyze the compressible flow in a blade coolant passage of an air-cooled gas turbine, a one-dimensional analysis was made including the combined effects of area change, wall friction, heat transfer, and rotation. The necessary numerical methods for the simultaneous solution of the resulting equations expressing the conservation of energy and momentum in differential form are presented. The solution of these equations can be greatly simplified with little loss in accuracy by employing constant mean values for the coefficients in the energy equation. Tables are presented in order to facilitate the required computations with the minimum of interpolation.

NACA RM E50E18

PRELIMINARY ANALYSIS OF PROBLEM OF DETERMINING EXPERIMENTAL PERFORMANCE OF AIR-COOLED TURBINE. III - METHODS FOR DETERMINING POWER AND EFFICIENCY. Herman H. Ellerbrock, Jr. and Robert R. Ziemer. August 2, 1950. 55p. diagrs. (NACA RM E50E18)

Suggested formulas are given for determining air-cooled turbine-performance characteristics, such as power and efficiency, as functions of certain parameters. These functions, generally being unknown, are determined from experimental data obtained from specific investigations. Special plotting methods for isolating the effect of each parameter are outlined.

NACA RM E50E22

PRELIMINARY ANALYSIS OF EFFECTS OF AIR COOLING TURBINE BLADES ON TURBOJET-ENGINE PERFORMANCE. Wilson B. Schramm, Alfred J. Nachtigall and Vernon L. Arne. August 2, 1950. 34p. diagrs., tab. (NACA RM E50E22)

The effects of turbine-blade cooling on engine performance were analytically investigated for a turbojet engine in which cooling air is bled from the engine compressor. The analysis was made for a constant turbine-inlet temperature and a range of altitudes to determine the minimum cooling requirements to permit substitution of nonstrategic materials in turbine blading. The results indicate that, for a constant inlet temperature, air cooling of the turbine blades increases the specific fuel consumption and decreases the thrust of the engine. The highest possible cooling effectiveness is desirable to minimize coolant weight flow and its effects on engine performance.

NACA RM E50F02

EXTENSION OF BOUNDARY-LAYER HEAT-TRANSFER THEORY TO COOLED TURBINE BLADES. W. Byron Brown and Patrick L. Donoughe. August 11, 1950. 51p. diagrs., tab. (NACA RM E50F02)

An equation for average heat transfer of a surface was derived when the boundary layer changed from laminar to turbulent. Influences on the heat transfer through a laminar boundary layer of Mach number, temperature ratio (gas temperature divided by wall temperature), and exponents of gas-property temperature relations were shown to be relatively small for air with Mach numbers less than 2 and temperature ratios between 1 and 4. Good agreement was obtained with experimental results from cylinders, an airfoil, and turbine blades.

NACA RM E50F05

EXPERIMENTAL AND ANALYTICAL STUDY OF BALANCED-DIAPHRAGM FUEL DISTRIBUTORS FOR GAS-TURBINE ENGINES. David M. Straight and Harold Gold. August 14, 1950. 62p. diagrs., photos. (NACA RM E50F05)

Eight possible fuel distributor arrangements for distributing fuel equally to a plurality of spray nozzles are presented and analyzed with emphasis on meeting fuel-system requirements of fuel-distribution accuracy, spray-nozzle pressure variations, and fuel-system pressures. The experimental performance of three distributors is discussed. Data are presented for a fuel distributor model distributing 19.5 to 862 pounds per hour of fuel to each of 10 spray nozzles with a maximum deviation of 3.3 percent from equal distribution. Methods for distributing wider ranges of fuel-flow rates are included.

NACA RM E50F09

ANALYTICAL DETERMINATION OF LOCAL SURFACE HEAT-TRANSFER COEFFICIENTS FOR COOLED TURBINE BLADES FROM MEASURED METAL TEMPERATURES. W. Byron Brown and Jack B. Esgar. August 11, 1950. 66p. diagrs. (NACA RM E50F09)

Analytical methods are presented for the determination of local values of outside and inside heat-transfer coefficients and effective gas temperatures by use of turbine-blade-temperature measurements. The methods are derived for a number of configurations that can be applied to typical cooled-turbine-blade shapes as well as to other types of heat-transfer apparatus.

NACA RM E50F14

EFFECT OF RETRACTABLE IGNITION PLUG ON PLUG FOULING BY CARBON DEPOSITS. Jerrold D. Wear and Theodore E. Locke. August 24, 1950. 25p. diagrs., photos. (NACA RM E50F14)

Investigations of ignition-plug fouling, starting, altitude combustion efficiencies, altitude operational limits, and combustor-outlet-temperature distribution with a retractable ignition plug and with a standard ignition plug were conducted. The retractable ignition plug did not become fouled when investigated with fuels and at engine conditions that did foul the standard plug. Starting, altitude combustion efficiencies, and altitude operational limits determined with the standard plug were unaffected by use of the retractable plug. A slightly improved temperature distribution was obtained with the retractable plug.

NACA RM E50G11

INVESTIGATION OF EFFECTS OF INLET-AIR VELOCITY DISTORTION ON PERFORMANCE OF TURBOJET ENGINE. E. William Conrad and Adam E. Sobolewski. September 13, 1950. 41p. diagrs., photos. (NACA RM E50G11)

To determine effect of nonuniform inlet-air velocities a full scale, axial-flow turbojet engine was investigated in Lewis altitude wind tunnel at altitudes from 20,000 to 50,000 feet, 0.21 flight Mach number and corrected engine speeds from 77.3 percent of rated speed to rated speed. Total-pressure variations as large as 103 pounds per square foot in radial direction and 90 pounds per square foot in circumferential direction at 30,000 feet were obtained. With the distortions investigated, net thrust varied between 0.95 and 1.03 of the thrust with uniform inlet-air distribution. Similarly the ratio of specific fuel consumption varied from 1.00 to 1.04. Within the range of this investigation, the effects of nonuniform inlet velocity were not serious for the engine investigated.

NACA RM E50G14

COMBUSTION EFFICIENCIES IN HYDROCARBON-AIR SYSTEMS AT REDUCED PRESSURES. Robert R. Hibbard, Isadore L. Drell, Allen J. Metzler and Adolph E. Spakowski. September 13, 1950. 12p. diagrs. (NACA RM E50G14)

In preliminary results obtained with quiescent fuel-air mixtures and with small diffusion flames, combustion efficiencies close to 100-percent were obtained at pressures much lower than those found in turbojet combustors at 60,000-foot altitude; in general, efficiencies were high at pressures approaching the limiting values for inflammation. Apparently, it is possible to burn flames with high efficiency at high altitudes if sufficient volume is available and undesired quenching processes do not occur. The reaction-zone volume required to effect a given rate of heat release rapidly increased with a decrease in pressure. It appears, however, that only a small fraction of the volume available in a turbojet combustor is required to effect the engine's design rate of heat release.

NACA RM E50I04

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. I - ROTOR BLADES WITH 10 TUBES IN COOLING-AIR PASSAGES. Herman H. Ellerbrock, Jr. and Francis S. Stepka. December 12, 1950. 76p. diagrs., photos., 2 tabs. (NACA RM E50I04)

The experimental results of air cooling turbine blades are presented herein. A method was developed for predicting cooled-blade temperatures by use of a temperature-difference ratio defined as φ and a calculated value of the solid-uncooled-blade temperature. By the use of this method predictions were made of the allowable turbine-inlet temperatures that may be attained with air cooling of turbine blades.

NACA RM E50I14

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. II - ROTOR BLADES WITH 15 FINS IN COOLING-AIR PASSAGES. Robert O. Hickel and Herman H. Ellerbrock, Jr. November 20, 1950. 56p. diagrs., photos., 3 tabs. (NACA RM E50I14)

A turbine-blade-cooling investigation was conducted on a modified production turbojet engine to determine experimentally the cooling effectiveness of a cooled blade with 15 fins inserted in the hollow blade shell. The results showed that the 15-fin blade cooled very well at the midchord, but that the leading and trailing edges were considerably hotter. The 15-fin blade showed increased cooling effectiveness, particularly near the midchord, over that of a blade with 10 tubes inserted in the blade shell investigated earlier.

NACA RM E50I15

ALTITUDE PERFORMANCE OF J35-A-17 TURBOJET ENGINE IN AN ALTITUDE CHAMBER. K. R. Vincent and B. M. Gale. January 3, 1951. 53p. diagrs., 3 tabs. (NACA RM E50I15)

Simulated flight performance of a J35-A-17 turbojet engine in an altitude chamber is presented for range of altitudes from 20,000 to 30,000 feet at flight Mach number of 0.62 and for range of flight Mach numbers from 0.42 to 1.22 at altitude of 30,000 feet. Performance variables jet thrust, net thrust, air flow, fuel flow, net-thrust specific fuel consumption, and tail-pipe total gas temperature are presented as functions of engine speed. Engine performance generalized for altitudes up to 30,000 feet and for flight Mach numbers at which critical flow exists in exhaust nozzle with the exception of corrected net thrust and net thrust specific fuel consumption.

NACA RM E50J06

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. III - ROTOR BLADES WITH 34 STEEL TUBES IN COOLING-AIR PASSAGES. Robert O. Hickel and Gordon T. Smith. December 11, 1950. 39p. diagrs., photos., 2 tabs. (NACA RM E50J06)

An experimental investigation to determine the cooling effectiveness of air-cooled turbine blades with 34 steel tubes inserted in the blade shell was made in a production turbojet engine over a range of engine speeds from 4000 to 9000 rpm and coolant flows from about 0.005 to 0.125 pound per second per blade. Results showed that only a limited increase, if any, in cooling effectiveness was obtained with the 34-tube blade over that of the 10-tube and 15-fin blades, which were previously investigated.

NACA RM E50J23

DETERMINATION OF GAS-TO-BLADE CONVECTION HEAT-TRANSFER COEFFICIENTS ON A FORCED-CONVECTION, WATER-COOLED SINGLE-STAGE ALUMINUM TURBINE. John C. Freche and Eugene F. Schum. January 3, 1951. 17p. diagrs., tab. (NACA RM E50J23)

Gas-to-blade convection heat-transfer coefficients were obtained on a forced-convection, water-cooled, single-stage aluminum turbine over a range of gas-flow Reynolds numbers, inlet-gas temperatures, and at several computed gas-flow inlet angles. The convection coefficients were correlated by the conventional Nusselt equation. Individual correlation curves were obtained for each gas-flow inlet angle. Comparison of the correlation curve obtained at the design gas-flow inlet angle with static-cascade results and with gas-to-blade heat-transfer results computed by boundary-layer theory showed close agreement.

NACA RM E50K01

INVESTIGATIONS OF SLOT CONFIGURATIONS FOR FILM-COOLED TURBINE BLADES BY FLOW VISUALIZATION METHODS. E. R. G. Eckert, Thomas W. Jackson and Allen C. Francisco. January 12, 1951. 57p. diagrs., photos. (NACA RM E50K01)

Two visual methods of obtaining qualitative information on the effectiveness of different slot configurations used to distribute cooling air around turbine blades are discussed. One method indicates the coolant coverage of the blade by means of a paint which changes its color under the influence of ammonia mixed with the cooling air. The other method makes the cooling air visible by mixing smoke with it. Cooling films generated by rows of cooling holes flush to the blade surface, rows of holes ending in grooves, and slots were studied.

NACA RM E50K10

EXPERIMENTAL INVESTIGATION OF EFFECTS OF DESIGN CHANGES ON PERFORMANCE OF LARGE-CAPACITY CENTRIFUGAL COMPRESSORS. Joseph R. Withee, Jr., Karl Kovach and Ambrose Ginsburg. March 2, 1951. 35p diagrs., photos., tab. (NACA RM E50K10)

An investigation was conducted to determine the effects of several design changes on the performance of large-capacity, double-entry, centrifugal compressors. Design changes that resulted in major improvements in performance were the use of a fully machined parabolic-blade inducer, increased impeller inlet-to-tip radius ratio, and a fully machined diffuser.

NACA RM E50K15

SURVEY OF ADVANTAGES AND PROBLEMS ASSOCIATED WITH TRANSPIRATION COOLING AND FILM COOLING OF GAS-TURBINE BLADES. E. R. G. Eckert and Jack B. Esgar. February 12, 1951. 39p. diagrs. (NACA RM E50K15)

An introduction to transpiration and film cooling methods as applied to gas-turbine blades is presented. The physical processes of these cooling methods are explained and information available for prediction of blade temperatures and heat-transfer rates is surveyed.

NACA RM E50L07

THERMAL CONDUCTIVITY OF 14 METALS AND ALLOYS UP TO 1100°F. Jerry E. Evans, Jr. March 2, 1951. 15p. diagrs., tab. (NACA RM E50L07)

The thermal conductivity of 14 metals and alloys was determined in temperature ranges having a maximum of 1100° F. The metals tested include steels, high-temperature alloys, molybdenum disilicide, aluminum alloys, brass, and silver. A comparison method was used to obtain the results in which the thermal conductivity of the test sample was compared with the conductivity of high-purity lead.

NACA RM E50L20

AVERAGE OUTSIDE-SURFACE HEAT-TRANSFER COEFFICIENTS AND VELOCITY DISTRIBUTIONS FOR HEATED AND COOLED IMPULSE TURBINE BLADES IN STATIC CASCADES. James E. Hubbartt and Eugene F. Schum. March 9, 1951. 35p. diagrs., photos. (NACA RM E50L20)

Gas-to-blade and blade-to-gas convective heat-transfer coefficients were experimentally obtained from a static cascade of impulse blades that could be heated or cooled. Blade peripheral velocities were measured and compared with calculated velocities obtained from a theory derived for impulse-type blades. The convective coefficients were correlated by the conventional Nusselt equation wherein Reynolds number was multiplied by a gas-to-blade temperature ratio. Blade peripheral calculated velocities were approximately 20 percent lower than measured velocities. Comparison of correlated curves for the heated and cooled blade with heat-transfer results computed by boundary-layer theory showed agreement within 4 percent at high experimental values of Reynolds number and 23 percent at low values.

NACA RM E51A03

A SUMMARY OF DESIGN INFORMATION FOR WATER-COOLED TURBINES. John C. Freche. March 9, 1951. 26p. diagrs. (NACA RM E51A03)

Information pertinent to the design of water-cooled turbines is tabulated. A design procedure is outlined. Calculation methods, design, fabrication, material, and operating considerations required for water-cooled turbine design are discussed.

NACA RM E51A19

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. IV - EFFECTS OF SPECIAL LEADING- AND TRAILING-EDGE MODIFICATIONS ON BLADE TEMPERATURE. Herman H. Ellerbrock, Jr., Charles F. Zalabak and Gordon T. Smith. April 13, 1951. 71p. diagrs., photos., 3 tabs. (NACA RM E51A19)

Six air-cooled blade configurations with special modifications for cooling the leading and trailing edges were fabricated and experimentally investigated in a production turbojet engine. Results of this investigation are presented and compared with results obtained from blade configurations previously investigated. The most promising of these blade designs may operate satisfactorily when fabricated of nonstrategic material at present turbine-inlet gas temperatures. General considerations necessary for cooled-blade design are discussed.

NACA RM E51A22

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. V - ROTOR BLADES WITH SPLIT TRAILING EDGES. Gordon T. Smith and Robert O. Hickel. April 2, 1951. 17p. diagrs., tab. (NACA RM E51A22)

An air-cooled turbine-blade configuration with special provision for cooling the trailing edge by passing cooling air through a series of radial slots was investigated. The results of this investigation are presented and compared to the results obtained from other blade configurations previously investigated.

NACA RM E51C09

EFFECT OF BLADE-SURFACE FINISH ON PERFORMANCE OF A SINGLE-STAGE AXIAL-FLOW COMPRESSOR. Jason J. Moses and George K. Serovy. April 16, 1951. 25p. diagrs., photos., 2 tabs. (NACA RM E51C09)

A set of modified NACA 5509-34 rotor and stator blades was investigated with rough-machined, hand-filed, and highly polished surface finishes over a range of weight flows at six equivalent tip speeds from 672 to 1092 feet per second to determine the effect of blade-surface finish on the performance of a single-stage axial-flow compressor. Surface-finish effects decreased with increasing compressor speed and with decreasing flow at a given speed. In general, finishing blade surfaces below the roughness that may be considered aerodynamically smooth on the basis of an admissible-roughness formula will have no effect on compressor performance.

NACA RM E51C29

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. VI - CONDUCTION AND FILM COOLING OF LEADING AND TRAILING EDGES OF ROTOR BLADES. Vernon L. Arne and Jack B. Esgar. May 18, 1951. 51p. diagrs., 3 tabs. (NACA RM E51C29)

A turbine-blade-cooling investigation was conducted on a modified commercial turbojet engine to determine experimentally the cooling and pressure-drop characteristics of a copper-clad conduction-cooled blade and three variations of a film-cooled blade. The copper-clad blade had very low temperature gradients combined with structural rigidity. All the film-cooled blades had high leading- and trailing-edge cooling effectiveness at high cooling-air flows, but the effectiveness tended to decrease rapidly as cooling-air flow was reduced below some critical value.

NACA RM E51D12

PRELIMINARY STUDY OF CIRCULATION IN AN APPARATUS SUITABLE FOR DETERMINING CORROSIVE EFFECTS OF HOT FLOWING LIQUIDS. Leland G. Desmon and Don R. Mosher. June 1951. 17p. diagrs., photos. (NACA RM E51D12)

A simple apparatus for inducing flow of a liquid medium in toroidal shaped channels is described. No pumps, valves or flow meters are required. The apparàtus is particularly applicable to the determination of the corrosive effects of flowing liquid metals on structural materials. Preliminary tests, wherein fluid velocities of 25 feet per second were obtained, are described.

NACA RM E51E07

SOME EFFECTS OF SOLIDITY ON TURNING THROUGH CONSTANT-THICKNESS CIRCULAR-ARC GUIDE VANES IN AXIAL ANNULAR FLOW. Harry Mankuta and Donald C. Guentert. August 1951. 19p. diagrs. (NACA RM E51E07)

An investigation was conducted on sheet-metal, circular arc compressor inlet guide vanes in an annular cascade with untapered walls to determine the effect of solidity on turning through a blade row. Guide vanes of 30° and 40° camber were investigated over a range of solidity from 0.5 to 4.0. An equation similar in form to Constant's rule that may be used to predict turning angles in cascades of configuration similar to that of this investigation was obtained from the data. Surveys made downstream of the guide vanes indicated that lower solidities than those presently used may be employed without exceeding loading limitations.

NACA RM E51E18

DETERMINATION OF BLADE-TO-COOLANT HEAT-TRANSFER COEFFICIENTS ON A FORCED-CONVECTION, WATER-COOLED, SINGLE-STAGE TURBINE. John C. Freche and Eugene F. Schum. July 1951. 25p. diagrs., 2 tabs. (NACA RM E51E18)

Blade-to-coolant convective heat-transfer coefficients were obtained on a forced-convection water-cooled single-stage turbine over a large laminar flow range and over a portion of the transition range between laminar and turbulent flow. The convective coefficients were correlated by the general relation for forced-convection heat transfer with laminar flow. Natural-convection heat transfer was negligible for this turbine over the Grashof number range investigated. Comparison of turbine data with stationary tube data for the laminar flow of heated liquids showed good agreement. Calculated average midspan blade temperatures using theoretical gas-to-blade coefficients and blade-to-coolant coefficients from stationary-tube data resulted in close agreement with experimental data.

NACA RM E51E21

EVALUATION OF CENTRIFUGAL COMPRESSOR PERFORMANCE WITH WATER INJECTION. William L. Beede, Joseph T. Hamrick and Joseph R. Withee, Jr. July 1951. 14p. diagrs. (NACA RM E51E21)

The effects of water injection on a compressor are presented. To determine the effects of varying water-air ratio, the compressor was operated at a constant equivalent impeller speed over a range of water-air ratios and weight flows. Operation over a range of weight flows at one water-air ratio and two inlet air temperatures was carried out to obtain an indication of the effects of varying inlet air temperature. Beyond a water-air ratio of 0.03 there was no increase in maximum air-weight flow, a negligible rise in peak total-pressure ratio, and a decrease in peak adiabatic efficiency. An increase in inlet air temperature resulted in an increase in the magnitude of evaporation. An analysis of data indicated that the magnitude of evaporation within the compressor impeller was small.

NACA RM E51E23

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. VII - ROTOR-BLADE FABRICATION PROCEDURES. Roger A. Long and Jack B. Esgar. September 1951. 30p. diagrs., photos. (NACA RM E51E23)

Fabrication procedures for a variety of air-cooled turbine-blade configurations, which were used in experimental investigations to determine the effectiveness of air-cooled blades in a turbojet engine, are presented. The blade shells were cast or formed from sheet metal or tubes. Additional heat-transfer surface was provided in the coolant passage by brazing fins or small tubes to the blade shell. Fabrication of blades with special methods of cooling leading and trailing edges is also discussed.

NACA RM E51E24

CALCULATED EFFECTS OF TURBINE ROTOR-BLADE COOLING-AIR FLOW, ALTITUDE, AND COMPRESSOR BLEED POINT ON PERFORMANCE OF A TURBOJET ENGINE. Vernon L. Arne and Alfred J. Nachtigall. August 1951. 24p. diagrs., 2 tabs. (NACA RM E51E24)

Effects of air-cooling turbine rotor blades on performance of a turbojet engine were calculated for a range of altitudes from sea level to 40,000 feet and a range of coolant flows up to 3 percent of compressor air flow, for two conditions of coolant bleed from the compressor. Bleeding at required coolant pressure resulted in a sea-level thrust reduction approximately twice the percentage coolant flow and in an increase in specific fuel consumption approximately equal to percentage coolant flow. For any fixed value of coolant flow ratio the percentage thrust reduction and percentage increase in specific fuel consumption decreased with altitude. Bleeding coolant at the compressor discharge resulted in an additional 1 percent loss in performance at sea level and in smaller increase in loss of performance at higher altitudes.

NACA RM E51F04

ANALYTICAL INVESTIGATION OF TWO LIQUID COOLING SYSTEMS FOR TURBINE BLADES. Thomas W. Jackson and John N. B. Livingood. August 1951. 27p. diagrs. (NACA RM E51F04)

A simplified analysis was made to determine flow characteristics and heat transfer in the laminar and turbulent flow regions for two turbine liquid-cooling systems, a straight-through-flow system and a recirculatory, or loop, flow system. Nondimensional charts, which simplify calculations of heat-transfer coefficients and coolant temperatures, are presented. Results of a sample calculation showed that, for a blade temperature of 1000° F, an increase in effective gas temperature of 350° F could be obtained by use of the loop cooling system instead of the straight-through system.

NACA RM E51F06

PERFORMANCE OF SINGLE-STAGE COMPRESSOR DESIGNED ON BASIS OF CONSTANT TOTAL ENTHALPY WITH SYMMETRICAL VELOCITY DIAGRAM AT ALL RADII AND VELOCITY RATIO OF 0.7 AT ROTOR HUB. Jack R. Burtt and Robert J. Jackson. September 1951. 14p. diagrs. (NACA RM E51F06)

A typical inlet axial-flow compressor inlet stage, which was designed on the basis of constant total enthalpy with symmetrical velocity diagram at all radii, was investigated. At a tip speed of 1126 feet per second, a peak pressure ratio of 1.28 was obtained at an efficiency of 0.76. At this tip speed, the highest practical flow was 28 pounds per second per square foot frontal area with an efficiency of 0.78. Data for a rotor relative inlet Mach number range of from 0.5 to 0.875 indicates that the critical value for any stage radial element is approximately 0.80 for the stage investigated.

NACA RM E51F22

CALCULATIONS OF LAMINAR HEAT TRANSFER AROUND CYLINDERS OF ARBITRARY CROSS SECTION AND TRANSPIRATION-COOLED WALLS WITH APPLICATION TO TURBINE BLADE COOLING. E. R. G. Eckert and John N. B. Livingood. September 1951. 57p. diagrs., 2 tabs. (NACA RM E51F22)

An approximate method for development of flow and thermal boundary layers in laminar regime on cylinders with arbitrary cross section and transpiration-cooled walls is obtained by use of Karman's integrated momentum equation and an analogous heat-flow equation. Incompressible flow with constant property values throughout boundary layer is assumed. Shape parameters for approximated velocity and temperature profiles and functions necessary for solution of boundary-layer equations are presented as charts, reducing calculations to a minimum. The method is applied to determine local heat-transfer coefficients and surface temperatures in the laminar region of transpiration-cooled turbine blades for a given flow rate. Coolant flow distributions necessary for maintaining uniform blade temperatures are also determined.

NACA RM E51G10

DETERMINATION AND USE OF THE LOCAL RECOVERY FACTOR FOR CALCULATING THE EFFECTIVE GAS TEMPERATURE FOR TURBINE BLADES. Jack B. Esgar and Alfred L. Lea. September 1951. 30p. diagrs., photos. (NACA RM E51G10)

In an experimental investigation of local recovery factors for a blade having a pressure distribution similar to that of a typical reaction-type turbine blade, it was found that the recovery factors were essentially independent of Mach number, Reynolds number, pressure gradient, and position on the blade surface except for regions where the boundary layer was probably in the transition range from laminar to turbulent. The recommended value of local subsonic recovery factor for use in calculating the effective gas temperature for gas turbine blades was 0.89.

NACA RM E51G30

PERFORMANCE OF A CASCADE IN AN ANNULAR VORTEX-GENERATING TUNNEL OVER RANGE OF REYNOLDS NUMBERS. Sidney Thurston and Ralph E. Brunk. September 1951. 33p. diagrs. (NACA RM E51G30)

Total-pressure deficiency for an annular cascade of 65-(12)10 blades was measured at three radial stations over a range of Reynolds numbers from 50,000 to 250,000 and at angles of attack of 15° and 25°. The variation of turning angle and shape of static pressure distribution at these stations is also shown.

NACA RM E51G31

PRELIMINARY INVESTIGATION OF MOLYBDENUM DISULFIDE - AIR-MIST LUBRICATION FOR ROLLER BEARINGS OPERATING TO DN VALUES OF 1×10^6 AND BALL BEARINGS OPERATING TO TEMPERATURES OF 1000° F. E. F. Macks, Z. N. Nemeth and W. J. Anderson. October 1951. 38p. diagrs., photos., 2 tabs. (NACA RM E51G31)

The effectiveness of molybdenum disulfide MoS_2 as a bearing lubricant was determined at high temperature and at high speeds. A 1-inch-bore ball bearing operated at temperatures to 1000° F, a speed of 1725 rpm, and a thrust load of 20 pounds when lubricated only with MoS_2-air mist. A 75-millimeter-bore cageless roller bearing, provided with a MoS_2-syrup coating before operation and lubricated with MoS_2-air mist during operation, operated at DN values to 1×10^6 with a load of 368 pounds.

NACA RM E51H14

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADE IN TURBOJET ENGINE. VIII - ROTOR BLADES WITH CAPPED LEADING EDGES. Gordon T. Smith and Robert O. Hickel. October 1951. 23p. diagrs., tab. (NACA RM E51H14)

An air-cooled turbine blade with a capped leading edge was investigated in a modified commercial turbojet engine over a range of engine speed from 4000 to 11,350 rpm. The cooling performance of the capped-leading-edge configuration was superior to all leading-edge cooling modifications previously investigated.

NACA RM E51I11

INVESTIGATIONS OF AIR-COOLED TURBINE ROTORS FOR TURBOJET ENGINES. I - EXPERIMENTAL DISK TEMPERATURE DISTRIBUTION IN MODIFIED J33 SPLIT-DISK ROTOR AT SPEEDS UP TO 6000 RPM. Wilson B. Schramm and Robert R. Ziemer. January 1952. 37p. diagrs., photos., 2 tabs. (NACA RM E51I11)

The experimental results of the disk temperature distribution in an air-cooled J33 split-disk turbine rotor fitted with nontwisted hollow air-cooled blades with nine tubes in the coolant passage are presented. These results were obtained at speeds up to 6000 rpm and the data correlated so that the disk temperatures at rated engine conditions could be estimated.

NACA RM E51I17

BLADE-TO-COOLANT HEAT-TRANSFER RESULTS AND OPERATING DATA FROM A NATURAL-CONVECTION WATER-COOLED SINGLE-STAGE TURBINE. Anthony J. Diaguila and John C. Freche. November 1951. 22p. diagrs., tab. (NACA RM E51I17)

Blade-to-coolant heat-transfer data and operating data were obtained with a natural-convection water-cooled turbine over a range of turbine speeds and inlet-gas temperatures. The convective coefficients were correlated by the general relation for natural-convection heat transfer. The turbine data were displaced from a theoretical equation for natural convection heat transfer in the turbulent region and from natural-convection data obtained with vertical cylinders and plates; possible disruption of natural convection circulation within the blade coolant passages was thus indicated. Comparison of nondimensional temperature-ratio parameters for the blade leading edge, midchord, and trailing edge indicated that the blade cooling effectiveness is greatest at the midchord and least at the trailing edge.

NACA RM E51J03

INVESTIGATIONS OF AIR-COOLED TURBINE ROTORS FOR TURBOJET ENGINES. II - MECHANICAL DESIGN, STRESS ANALYSIS, AND BURST TEST OF MODIFIED J33 SPLIT-DISK ROTOR. Richard H. Kemp and Merland L. Moseson. January 1952. 46p. diagrs., photos., tab. (NACA RM E51J03)

A full-scale J33 air-cooled split turbine rotor was designed and spin-pit tested to destruction. Stress analysis and spin-pit results indicated that the rotor was structurally sound. Operation of a similar rotor in a J33 turbojet engine, however, showed that the rear disk of the rotor operated at temperatures substantially higher than the forward disk. An extension of the stress analysis to include the temperature difference between the two disks indicated that engine modifications are required to permit operation of the two disks at more nearly the same temperature level.

NACA RM E51J10

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. IX - EVALUATION OF THE DURABILITY OF NONCRITICAL ROTOR BLADES IN ENGINE OPERATION. Francis S. Stepka and Robert O. Hickel. December 1951. 26p. diagrs., photos., 4 tabs. (NACA RM E51J10)

The durability of five different structural or cooling configurations or combination of both of air-cooled blades made of noncritical materials was investigated in a modified turbojet engine. The greater part of the investigation was conducted at an engine speed of 11,500 rpm, a turbine-inlet temperature of approximately 1670° F, and a cooling-air to combustion gas flow ratio per blade of 0.05. The results of the investigation indicated that air-cooled blades made of noncritical metals can be operated for extended periods of time in engines at current inlet temperatures; however, before these blades are considered completely satisfactory for gas-turbine application, some means such as coatings is required to inhibit the oxidation of the blades.

NACA RM E51K02

EXPERIMENTAL INVESTIGATION OF COOLANT-FLOW CHARACTERISTICS OF A SINTERED POROUS TURBINE BLADE. Edward R. Bartoo, Louis J. Schafer, Jr. and Hadley T. Richards. February 1952. 28p. diagrs., photos. (NACA RM E51K02)

Local cooling-air flow rates through the walls of a sintered porous-metal turbine blade were measured at room temperature for a range of pressure drops. In order to check the validity of the correlation procedure, this procedure was used to correlate air-flow rates through two porous disks at temperatures up to 600° F. Data indicate the method permits room-temperature flow data to be used for heat-transfer work at elevated temperatures with reasonable accuracy. Cooling-air flow distribution around the periphery of the test blade is presented for two internal cooling air pressures with the blade in a 1000° F gas stream at a cascade-inlet Mach number of 0. 45.

NACA RM E51K08

EXPERIMENTAL INVESTIGATION OF THE HEAT-TRANSFER CHARACTERISTICS OF AN AIR-COOLED SINTERED POROUS TURBINE BLADE. Louis J. Schafer, Jr., Edward R. Bartoo and Hadley T. Richards. February 1952. 33p. diagrs., photos. (NACA RM E51K08)

The results of a heat-transfer investigation on a transpiration-cooled turbine blade are presented. The investigation was made on a static cascade. Blade-peripheral wall-temperature distributions were measured and compared with the temperature distribution on a convection-cooled blade. A correlation of the blade-wall temperatures obtained at various gas temperatures and gas weight flows was made on the basis of a temperature-difference ratio. Blade-wall temperatures calculated using an approximate theory for turbulent flow are compared with the measured blade-wall temperatures.

NACA RM E52A04

OXIDATION-RESISTANCE MECHANISM AND OTHER PROPERTIES OF MOLYBDENUM DISILICIDE. W. A. Maxwell. March 1952. 17p. diagrs., photos., tab. (NACA RM E52A04)

The outstanding oxidation resistance of molybdenum disilicide at 2400° F and above was found to depend on the formation of a protective siliceous coating in which α-cristobalite has been identified. Molybdenum disilicide is not inherently resistant to oxidation and in powdered form burns at low temperatures. Melting and casting experiments have demonstrated the decomposition of the material at the melting point. The room-temperature modulus of elasticity has been determined and electric-resistivity data are given to 2000° F.

NACA RM E52B13

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. X - ENDURANCE EVALUATION OF SEVERAL TUBE-FILLED ROTOR BLADES. Jack B. Esgar and John L. Clure. May 1952. 45p. diagrs., photos., 5 tabs. (NACA RM E52B13)

Results are presented of endurance investigations of a variety of air-cooled tube-filled turbine-rotor blades to evaluate (1) new shell-to-base attachment methods, (2) coatings for providing oxidation resistance, and (3) durability of improved type of blade at reduced coolant-flow rates. The improved type of blade could operate satisfactorily at rated-speed endurance conditions at coolant-flow ratios as low as 0.03, but oxidation limited the blade life even though the blades were protected with the coatings that were investigated.

NACA RM E52C12

INVESTIGATIONS OF AIR-COOLED TURBINE ROTORS FOR TURBOJET ENGINES. III- EXPERIMENTAL COOLING-AIR IMPELLER PERFORMANCE AND TURBINE ROTOR TEMPERATURES IN MODIFIED J33 SPLIT-DISK ROTOR UP TO SPEEDS OF 10,000 RPM. Alfred J. Nachtigall, Charles F. Zalabak and Robert R. Ziemer. May 1952. 42p. diagrs., photos., 3 tabs. (NACA RM E52C12)

The experimental results of the cooling-air impeller performance and the turbine rotor temperature distributions in an air-cooled J33 split-disk turbine rotor fitted with air-cooled, tube-filled blades are presented for engine speeds up to 10,000 rpm. Engine alterations which reduced the temperature-level difference between the forward and rear disks of the rotor permitted operation over the extended speed range. Disk temperature data were correlated so that disk temperatures at rated engine conditions could be estimated. Calculated disk stresses at rated engine conditions are presented and indicate that the configuration investigated is structurally sound.

NACA RM E52D01

PRESSURE DROP IN COOLANT PASSAGES OF TWO AIR-COOLED TURBINE-BLADE CONFIGURATIONS. W. Byron Brown and Henry O. Slone. June 1952. 57p. diagrs., photos., tab. (NACA RM E52D01)

Friction coefficients were experimentally determined for both isothermal and nonisothermal flows in a pressure drop investigation conducted on two air-cooled turbine-blade configurations. A reasonable check was obtained between the air-cooled-blade friction coefficients. The data were used to develop a simplified flow equation for calculating over-all pressure drops through air-cooled blades and to examine the magnitude of entrance losses which might be expected in the entrance sections of air-cooled blades. A procedure that may be used for the calculation of air-cooled-blade pressure drops is presented.

NACA RM E52D21

COMPARISON OF CALCULATED AND EXPERIMENTAL TEMPERATURES OF WATER-COOLED TURBINE BLADES. Eugene F. Schum, John C. Freche and William J. Stelpflug. July 1952. 36p. diagrs., 3 tabs. (NACA RM E52D21)

Analytical methods were applied to calculate average and local blade temperatures and maximum allowable inlet gas temperatures for a forced-convection, water-cooled aluminum turbine. Comparison of calculated with experimental temperatures, obtained over a gas-temperature range from 400° to 1600° F, resulted in generally good agreement. A stationary water-cooled low-conductivity material (stainless steel) blade with a high-conducitivty material (copper) inserted in the trailing edge was also investigated over a gas-temperature range from 400° to 900° F and proved to be an effective method of reducing the trailing-edge temperature. Calculated trailing edge temperatures agreed well with experimental data.

NACA RM E52F23

RADIANT HEAT TRANSFER FROM FLAMES IN A SINGLE TUBULAR TURBOJET COMBUSTOR. Leonard Topper. August 1952. 30p. diagrs., tab. (NACA RM E52F23)

An experimental investigation of thermal radiation from the flame of a single tubular turbojet-engine combustor to the combustor liner is presented. The effects of combustor inlet-air pressure, air mass flow, and fuel-air ratio on the radiant intensity and on the temperature and emissivity of the flame are reported. The total radiation of the "luminous" flames (containing incandescent soot particles) was much greater (4 to 21 times) than the "nonluminous" molecular radiation. The intensity of radiation from the flame increased rapidly with an increase in combustor inlet-air pressure; it was affected to a lesser degree by variations in fuel-air ratio and air mass flow.

NACA RM E52F30

EXPERIMENTAL INVESTIGATION OF FREE-CONVECTION HEAT TRANSFER IN VERTICAL TUBE AT LARGE GRASHOF NUMBERS. E. R. G. Eckert and A. J. Diaguila. August 1952. 37p. diagrs., photos., tab. (NACA RM E52F30)

Local free-convection heat-transfer coefficients and temperature fields in the turbulent flow range were obtained within a vertical, stationary tube closed at the bottom, heated along its walls, and having a length-to-diameter ratio of 5. Convective heat-transfer coefficients were correlated by the general relations for free-convection heat transfer. These coefficients, converted to dimensionless Nusselt numbers were 35 percent below known relations for vertical flat plates. Air temperature measurements within the tube indicated a thin boundary layer along the heated wall surface and unstable conditions in the air flow.

NACA RM E52G11

CARBON-DEPOSITION CHARACTERISTICS OF MIL-F-5624A FUELS CONTAINING HIGH-BOILING AROMATIC HYDROCARBONS. Edmund R. Jonash, Jerrold D. Wear and William P. Cook. August 1952. 11p. diagrs., photos., 2 tabs. (NACA RM E52G11)

The effects of additions of typical high-boiling single-ring and dicyclic aromatic hydrocarbons (triisopropylbenzene and monomethylnaphthalene) on the carbon deposition characteristics of MIL-F-5624A, grade JP-3 and JP-4, fuel were determined in a single J33 combustor. The addition of the aromatic hydrocarbon components increased the carbon-deposition characteristics of the base fuels. These effects were satisfactorily predicted by the NACA K factor and the smoking tendency correlations previously developed.

NACA RM E52H05

INVESTIGATION OF TITANIUM CARBIDE BASE CERAMALS CONTAINING EITHER NICKEL OR COBALT FOR USE AS GAS-TURBINE BLADES. C. A. Hoffman and A. L. Cooper. August 1952. 33p. photos., diagrs., 5 tabs. (NACA RM E52H05)

The following two materials were investigated for use as gas-turbine-blade material: 65 percent TiC plus 20 percent Co plus 15 percent (CbTaTi)C and 65 percent TiC plus 20 percent Ni plus 15 percent (CbTaTi)C. Concurrently, the effectiveness of a number of methods of preventing ceramal-blade-root failure was studied. Blade temperatures from 1500° to 1900° F and wheel speeds from 10,000 to 26,000 rpm were used. Stellite 21 and S-816 alloy blades were used for comparison. Prior to the blade evaluation, physical-property evaluations of the ceramals were made. The results indicate that both the 66.5 percent TiC plus 18.5 percent Co plus 15 percent (CbTaTi)C and 66.5 percent TiC plus 18.5 percent Ni and 15 percent (CbTaTi)C ceramals should be considered further for gas-turbine-blade use. The oxidation resistance of either of these materials appears to be adequate for practical blade application. Further work on blade root design and mounting methods is required to eliminate root failure as the factor limiting the usefulness of these ceramals as gas turbine blade material.

NACA RM E52H19

INVESTIGATION OF EFFECTS OF REYNOLDS NUMBER ON LARGE DOUBLE-ENTRY CENTRIFUGAL COMPRESSOR. Karl Kovach and Joseph R. Withee, Jr. October 1952. 26p. diagrs. (NACA RM E52H19)

An investigation was conducted on a large-capacity double-entry centrifugal compressor to determine the effects of Reynolds number on over-all performance and also to obtain some idea of the origin and nature of the effects. The decreases in over-all performance at design tip speed (1545 ft/sec) for a change in pressure altitude from 20,000 to 50,000 feet were: (1) peak total-pressure ratio, 3.4 percent, (2) maximum equivalent weight flow, 3.8 percent, and (3) peak efficiency, 0.02. The origin of at least part of the Reynolds number effects in this compressor is in the inlet and the inducer sections.

NACA RM E52H28

INVESTIGATION OF AXIALLY SYMMETRIC AND TWO-DIMENSIONAL MULTINOZZLES FOR PRODUCING SUPERSONIC STREAMS. Eli Reshotko and Rudolph C. Haefeli. October 1952. 35p. diagrs., photos., tab. (NACA RM E52H28)

The flow characteristics of three axially symmetric multinozzles of nominal design Mach numbers 3.46, 3.07, and 7.01 and a two-dimensional multinozzle of nominal design Mach number 3.07 were investigated. Three types of disturbance, classified as oblique shock waves, corner shock waves, and wakes, were observed in the flow fields. The effect of the geometry of the multinozzles on these disturbances and on the actual Mach number and pressure recovery obtained with the multinozzle is discussed herein. The magnitude of the disturbances was found to depend on the exit turning angle of the individual nozzles. Generally, Mach number variations of 4-1/2 percent or less existed in a region which could be used as a test section. The use of multinozzles, however, appears to be restricted to experiments in which nonuniformity of flow and large pressure losses can be tolerated and for which simple fabrication and quick interchange of nozzles are desired.

NACA RM E52J31

EXPERIMENTAL INVESTIGATION OF RADOME ICING AND ICING PROTECTION. James P. Lewis and Robert J. Blade. January 1953. 60p. diagrs., photos. (NACA RM E52J31)

In an investigation of radome icing and icing protection in the NACA Lewis icing research tunnel, the impingement of water and the formation of ice on two radome configurations were found to agree well with theory and experience. The ice formations on the radomes produced serious effects on radar performance. The ethylene glycol fluid-protection system gave adequate icing protection for both anti-icing and de-icing. The radomes were investigated at airspeeds up to 290 miles per hour, air total temperatures of -15° to 20° F, water contents up to 1.0 gram per cubic meter, and angles of attack of 0° and 4°.

NACA RM E52L15a

PRELIMINARY INVESTIGATION OF ZIRCONIUM BORIDE CERAMALS FOR GAS-TURBINE BLADE APPLICATIONS. Charles A. Hoffman. April 1953. 13p. photos., diagrs., 2 tabs. (NACA RM E52L15a)

Zirconium boride ZrB_2 ceramals were investigated for possible gas-turbine-blade application. Included in the study were thermal shock evaluations of disks, preliminary turbine-blade operation, and observations of oxidation resistance. Thermal shock disks of the following three compositions were studied: (a) 97.5 percent ZrB_2 plus 2.5 percent B by weight; (b) 92.5 percent ZrB_2 plus 7.5 percent B by weight; and (c) 100 percent ZrB_2. Thermal shock disks were quenched from temperatures of 1800°, 2000°, 2200°, and 2400° F. The life of turbine blades containing 93 percent ZrB_2 plus 7 percent B by weight was determined in gas-turbine tests. The blades were run at approximately 1600° F and 15,000 to 26,000 rpm. The thermal shock resistance of the 97.5 percent ZrB_2 plus 2.5 percent boron ceramals compares favorably with that of TiC plus Co and TiC plus Ni ceramals. Oxidation of the disks during the thermal shock evaluation was slight for the comparatively short time (8.3 hr) up through 2000° F. Oxidation of a specimen was severe, however, after 100 hours at 2000° F. The turbine blade performance evaluation of the 93 percent ZrB_2 plus 7 percent B composition was preliminary in scope; no conclusions can be drawn.

NACA RM E52L19a

EXPERIMENTAL INVESTIGATION OF A LIGHT-WEIGHT ROCKET CHAMBER. John E. Dalgleish and Adelbert O. Tischler. March 1953. 12p. photos. (NACA RM E52L19a)

Experiments have been conducted with a jacketed rocket combustion chamber that was fabricated by hydraulic-forming from sheet metal. Rocket combustion chambers made by this method have been used successfully. Runs with these combustion chambers have been made at over-all heat-transfer rates of 1.7 Btu per square inch per second with water cooling and also with ammonia as a regenerative coolant.

NACA RM E52L31

THERMAL-SHOCK RESISTANCE OF A CERAMIC COMPRISING 60 PERCENT BORON CARBIDE AND 40 PERCENT TITANIUM DIBORIDE. C. M. Yeomans and C. A. Hoffman. March 1953. 7p. photos., 3 tab. (NACA RM E52L31)

Thermal-shock resistance of a ceramic comprising 60 percent boron carbide and 40 percent titanium diboride was investigated. The material has thermal shock resistance comparable to that of NBS body 4811C and that of zirconia, but is inferior to beryllia, alumina, and titanium-carbide ceramals. It is not considered suitable for turbine blades.

NACA RM E53A21

FUEL CHARACTERISTICS PERTINENT TO THE DESIGN OF AIRCRAFT FUEL SYSTEMS. Henry C. Barnett and R. R. Hibbard. June 1953. i, 104p. diagrs., 9 tabs. (NACA RM E53A21)

Because of the importance of fuel properties in design of aircraft fuel systems the present report has been prepared to provide information on the characteristics of current jet fuels. In addition to information on fuel properties, discussions are presented on fuel specifications, the variations among fuels supplied under a given specification, fuel composition, and the pertinence of fuel composition and physical properties to fuel system design. In some instances the influence of variables such as pressure and temperature on physical properties is indicated. References are cited to provide fuel system designers with sources of information containing more detail than is practicable in the present report.

NACA RM E53E25

ANALYTICAL INVESTIGATION OF FUEL TEMPERATURES AND FUEL-EVAPORATION LOSSES ENCOUNTERED IN LONG-RANGE HIGH-ALTITUDE SUPERSONIC FLIGHT. Richard J. McCafferty. August 1953. 38p. diagrs., 2 tabs. (NACA RM E53E25)

Two types of fuel losses were considered, loss due to adiabatic evaporation during climb and loss due to aerodynamic-heating effects. Heat-balance relations were employed to estimate amount of heat transferred to fuel contained in a cylindrical fuselage. Influence of flight speed, flight altitude, fuel withdrawal rate, tank size, tank pressurization, insulation, and initial fuel temperature on evaporation of JP-4 fuel was predicted. Influence of fuel volatility was determined by comparing evaporation obtained with JP-4 fuel and that obtained with JP-5. Results of analysis predicted, for an uninsulated tank, JP-4 fuel-boiling losses of 38 percent of total fuel weight carried by aircraft at the maximum flight speed and altitude considered. Fuel losses increased with increasing flight speed and flight time but decreased with increasing altitude. Fuel loss caused by adiabatic evaporation could be eliminated by ground refrigeration, tank pressurization, or use of low volatility fuel. Fuel loss due to aerodynamic heating could be eliminated by a combination of insulation of a practical thickness and use of a low volatility fuel; however, if tank pressurization were employed without insulation excessive pressures would be required. Without insulation, a maximum liquid-fuel temperature of 740° F would result if no fuel cooling occurred as a result of fuel evaporation; high liquid-fuel temperatures may create additional fuel handling problems.

NACA RM E53F03

THE SYNTHESIS OF BUTYLSILANES BY A LARGE-SCALE REDUCTION WITH LITHIUM ALUMINUM HYDRIDE. Samuel Kaye, Stanley Tannenbaum and Harold F. Hipsher. July 1953. 12p. photos., diagr. (NACA RM E53F03)

Eighty pounds of butylsilanes required for test purposes was synthesized by reducing butyltrichlorosilane with lithium aluminum hydride in dioxane solution. This was safely and successfully accomplished by operating in steel equipment under an atmosphere of oil-pumped nitrogen to minimize the hazards involved in conducting this operation on a large scale. The apparatus and procedure used to carry out the necessary manipulations are described in this report.

NACA RM E53F26

THERMAL SHOCK RESISTANCE AND HIGH-TEMPERATURE STRENGTH OF A MOLYBDENUM DISILICIDE - ALUMINUM OXIDE CERAMIC. W. A. Maxwell and R. W. Smith. October 1953. 8p. photo., 4 tabs. (NACA RM E53F26)

A ceramic having the nominal composition 75 percent molybdenum disilicide, 25 percent aluminum oxide was evaluated in thermal shock by two methods and high-temperature modulus-of-rupture strengths were determined. The material was found to have improved thermal-shock resistance as compared with pure molybdenum disilicide and to have moderate high-temperature strength.

NACA RM E53I16

FUEL CHARACTERISTICS PERTINENT TO THE DESIGN OF AIRCRAFT FUEL SYSTEMS. SUPPLEMENT I - ADDITIONAL INFORMATION ON MIL-F-7914(AER) GRADE JP-5 FUEL AND SEVERAL FUEL OILS. Henry C. Barnett and Robert R. Hibbard. (Supplement to RM E53A21) November 1953. 39p. diagrs., 3 tabs. (NACA RM E53I16)

Since the release of the first NACA publication of fuel characteristics pertinent to the design of aircraft fuel systems, additional information has become available on MIL-F-7914(AER) grade JP-5 fuel and several of the current grades of fuel oils. In order to make this information available to fuel-system designers as quickly as possible, the present report has been prepared as a supplement to NACA RM E53A21, "Fuel Characteristics Pertinent to the Design of Aircraft Fuel Systems" by Henry C. Barnett and R. R. Hibbard, 1953.

NACA RM L50A04a

MAXIMUM-LIFT CHARACTERISTICS OF A WING WITH THE LEADING-EDGE SWEEPBACK DECREASING FROM 45° AT THE ROOT TO 20° AT THE TIP AT REYNOLDS NUMBERS FROM 2.4×10^6 TO 6.0×10^6. Roy H. Lange. July 6, 1950. 62p. diagrs., photos. (NACA RM L50A04a)

Results are presented of an investigation of the maximum lift characteristics of a wing with the leading-edge sweepback decreasing from 45° at the root to 20° at the tip. The investigation was made for conditions of leading edge smooth and leading edge rough for the basic wing and for the wing with split flaps, leading-edge flaps, outboard slats, and combinations of these high-lift devices at Reynolds numbers from 2.4×10^6 to 6.0×10^6.

NACA RM L50A23a

LOW-SPEED PRESSURE-DISTRIBUTION MEASUREMENTS AT A REYNOLDS NUMBER OF 3.5×10^6 ON A WING WITH LEADING-EDGE SWEEPBACK DECREASING FROM 45° AT THE ROOT TO 20° AT THE TIP. U. Reed Barnett, Jr. and Roy H. Lange. July 7, 1950. 39p. diagrs., photo. (NACA RM L50A23a)

Results are presented of an investigation to determine the pressure distributions over a wing with the leading-edge sweepback decreasing from 45° at the root to 20° at the tip. Tests were made at a Reynolds number of 3.5×10^6 and a Mach number of 0.07 on the wing with and without 60° split flaps.

NACA RM L50C02

LOW-SPEED PITCHING DERIVATIVES OF LOW-ASPECT-RATIO WINGS OF TRIANGULAR AND MODIFIED TRIANGULAR PLAN FORMS. Alex Goodman and Byron M. Jaquet. April 17, 1950. 25p. diagrs., photos., 2 tabs. (NACA RM L50C02)

The present paper presents results of an investigation made in the Langley stability tunnel to determine effects of change in profile and aspect ratio on pitching derivatives of triangular and modified triangular wings. Results were compared with available theories.

NACA RM L50C15a

EXPERIMENTAL INVESTIGATION OF THE EFFECT OF ASPECT RATIO AND MACH NUMBER ON THE FLUTTER OF CANTILEVER WINGS. E. Widmayer, Jr., W. T. Lauten, Jr. and S. A. Clevenson. June 1, 1950. 20p. diagrs., 2 tabs. (NACA RM L50C15a)

The results of some wind-tunnel experiments to investigate the effects of aspect ratio and Mach number on the flutter of uniform, unswept, cantilever wings are reported. Models having aspect ratios ranging from 2 to 13 were tested at Mach numbers up to 0.92. No general attempt is made to correlate the data with three-dimensional-flow theory, but an examination of the data is made on the basis of reference theoretical values obtained from the two-dimensional incompressible flow theory. On this basis a reduction in aspect ratio, in general, increased the ratio of the experimental flutter speed to the calculated flutter speed. The analysis also indicated that for a given aspect ratio, this ratio decreased slightly as the Mach number is increased.

NACA RM L50D06

ABILITY OF PILOTS TO CONTROL SIMULATED SHORT-PERIOD YAWING OSCILLATIONS. William H. Phillips and Donald C. Cheatham. November 13, 1950. 23p. diagrs., photos., tab. (NACA RM L50D06)

The results of an investigation of pilot's ability to control short-period yawing oscillations in a simulating device are presented. Pilot's ability to control the short-period yawing oscillations has been determined as a function of period, control effectiveness, and inherent damping or instability.

NACA RM L50D07

PRESSURE-RISE AND LEAKAGE-LOSS CHARACTERISTICS OF A ROTATING COWLING. Jack F. Runckel and Gerald Hieser. August 30, 1950. 47p. diagrs., photos. (NACA RM L50D07)

Presents results of an investigation of pressure-rise and leakage-loss characteristics of a rotating cowling. A method for predicting the pressure rise is developed and compared with the results obtained experimentally. Design considerations peculiar to this type of cowling are discussed, and methods for estimating the leakage flow and proper setting of the cowling vane are outlined.

NACA RM L50D13

A WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF THRUST-AXIS INCLINATION ON PROPELLER FIRST-ORDER VIBRATION. W. H. Gray, J. M. Hallissy, Jr. and A. R. Heath, Jr. June 9, 1950. 64p. diagrs., photo., tab. (NACA RM L50D13)

Data are presented on aerodynamic excitation of propeller vibration with the thrust axis at two angles of inclination to the air stream. Aerodynamic excitation is calculated and compared with measured values for several conditions. Measured and calculated blade vibratory stresses for several excitation values are presented. The calculated values of exciting force compared well with the measured values at low rotational speeds, not so well at high rotational speeds. First-order blade vibratory stresses were computed with satisfactory accuracy from unpitched propeller loading data.

NACA RM L50D14

LOW-SPEED LATERAL STABILITY AND AILERON-EFFECTIVENESS CHARACTERISTICS AT A REYNOLDS NUMBER OF 3.5 x 10^6 OF A WING WITH LEADING-EDGE SWEEPBACK DECREASING FROM 45° AT THE ROOT TO 20° AT THE TIP. Roy H. Lange and Huel C. McLemore. July 6, 1950. 44p. diagrs., photos. (NACA RM L50D14)

Results are presented of an investigation of the static lateral stability and aileron-effectiveness characteristics of a wing with the leading-edge sweepback decreasing from 45° at the root to 20° at the tip. The investigation is made for the basic wing and for the wing with split flaps, leading-edge flaps, outboard slats, and combinations of these high-lift devices at a Reynolds number of about 3.5 x 10^6.

NACA RM L50E02

LOW-SPEED INVESTIGATION OF LEADING-EDGE AND TRAILING-EDGE FLAPS ON A 47.5° SWEPTBACK WING OF ASPECT RATIO 3.4 AT A REYNOLDS NUMBER OF 4.4 x 10^6. Jerome Pasamanick and Thomas B. Sellers. June 12. 1950. 29p. diagrs.. photo. (NACA RM L50E02)

Presents results of an investigation in the Langley full-scale tunnel of various extensible leading-edge and plain trailing-edge flaps on a wing-fuselage combination. The wing leading-edge sweep was 47.5°, the aspect ratio was 3.4, the taper ratio was 0.51, and the airfoil sections were NACA 64_1A112. The data include the effects of flap design parameters on the lift, drag, and pitching-moment characteristics at zero yaw for a range of angle of attack at a Reynolds number of 4.4 x 10^6.

NACA RM L50E12a

EFFECT OF VARIOUS OUTBOARD AND CENTRAL FINS ON LOW-SPEED YAWING STABILITY DERIVATIVES OF A 60° DELTA-WING MODEL. Alex Goodman. June 19, 1950. 35p. diagrs., photos., 2 tabs. (NACA RM L50E12a)

The results of an investigation conducted in the Langley stability tunnel to determine the effects of various outboard- and central-fin arrangements on the low-speed yawing stability derivatives of a 60° delta-wing model are presented. Calculated values of the effective center of pressure for several of the central fins are also presented. Procedures are suggested for estimating the contribution of fins to the stability derivatives of similar model configurations.

NACA RM L50F16

LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A SERIES OF SWEPT WINGS HAVING NACA 65A006 AIRFOIL SECTIONS. (Revised) Jones F. Cahill and Stanley M. Gottlieb. October 17, 1950. 63p. diagrs., photos. (NACA RM L50F16. Formerly RM L9J20)

An investigation was made to determine the effect of sweep, taper ratio, and aspect ratio on the aerodynamic characteristics of nine semispan wings of NACA 65A006 airfoil section with and without split flaps. Lift, drag, pitching-moment, and wing-root bending-moment characteristics were measured through a range of Reynolds numbers from 1.5 x 10^6 to 12.0 x 10^6. One of these wings was tested with a hinged leading-edge flap of various spans and deflections to determine the effect of this type of flap on longitudinal stability near maximum lift.

NACA RM L50F16a

LOW-SPEED LONGITUDINAL CHARACTERISTICS OF A CIRCULAR-ARC 52° SWEPTBACK WING OF ASPECT RATIO 2.84 WITH AND WITHOUT LEADING-EDGE AND TRAILING-EDGE FLAPS AT REYNOLDS NUMBERS FROM 1.6 x 10^6 TO 9.7 x 10^6. Gerald V. Foster and Roland F. Griner. August 11, 1950. 40p. diagrs., photo., tab. (NACA RM L50F16a)

The results of low-speed tests of a 52° swept wing which had circular-arc sections are presented. The wing exhibited large changes in stability from the low to high lift range. The stability of the wing was improved with the addition of leading-edge flaps which extended over 25 percent of the wing semispan. The aerodynamic characteristics of the wing were not appreciably affected by the variation of Reynolds numbers.

NACA RM L50G17

WIND-TUNNEL INVESTIGATION OF THE LOW-SPEED LONGITUDINAL AND LATERAL CONTROL CHARACTERISTICS OF A TRIANGULAR-WING MODEL OF ASPECT RATIO 2.31 HAVING CONSTANT-CHORD CONTROL SURFACES. Walter D. Wolhart and William H. Michael, Jr. September 6, 1950. 41p. diagrs., photo., 2 tabs. (NACA RM L50G17)

Results are presented of a wind-tunnel investigation of low-speed longitudinal and lateral control characteristics of a model with a triangular wing having NACA $65_{(06)}$-006.5 airfoil sections and aspect ratio 2.31 and equipped with constant-chord control surfaces. The investigation included determination of effects of adding fuselage to wing, adding transition strips, varying the Reynolds number from 1.62×10^6 to 2.62×10^6, and sealing the gap at the nose of the control surface.

NACA RM L50H29

POSITIONING INVESTIGATION OF SINGLE SLOTTED FLAPS ON A 47.7° SWEPTBACK WING AT REYNOLDS NUMBERS OF 4.0×10^6 AND 6.0×10^6. Stanley H. Spooner and Ernst F. Mollenberg. October 9, 1950. 36p. diagrs., photo., 3 tabs. (NACA RM L50H29)

The relationship between flap effectiveness and the horizontal and vertical position of a partial-span single slotted flap on a 47.7° sweptback-wing - fuselage combination is shown. Included are some effects of Reynolds number variation and a comparison with two-dimensional positioning studies of a slotted flap. The low-speed investigation was conducted in the Langley 19-foot pressure tunnel at Reynolds numbers of 4.0×10^6 and 6.0×10^6.

NACA RM L50I29

DESCRIPTION AND ANALYSIS OF A ROCKET-VEHICLE EXPERIMENT ON FLUTTER INVOLVING WING DEFORMATION AND BODY MOTIONS. H. J. Cunningham and R. R. Lundstrom. November 30, 1950. 27p. diagrs., photos., 2 tabs. (NACA RM L50I29)

Flight tests and a mathematical analysis were carried out to demonstrate and confirm a type of subsonic flutter involving rigid-body motions and wing deformations. For the configuration considered, the period of the oscillation was approximately 100 chords per cycle which is well within the range of period found in dynamic-stability work on rigid aircraft with free controls. A mathematical analysis based on two-dimensional incompressible flow provided a conservative prediction of the airspeed at which the low-frequency flutter occurred. It was found that wing-bending stiffness is the important parameter for preventing such flutter.

NACA RM L50L11

THEORETICAL AND ANALOG STUDIES OF THE EFFECTS OF NONLINEAR STABILITY DERIVATIVES ON THE LONGITUDINAL MOTIONS OF AN AIRCRAFT IN RESPONSE TO STEP CONTROL DEFLECTIONS AND TO THE INFLUENCE OF PROPORTIONAL AUTOMATIC CONTROL. Howard J. Curfman, Jr. February 23, 1951. 55p. diagrs., photos. (NACA RM L50L11)

Through theoretical and analog results the effects of two nonlinear stability derivatives on the longitudinal motions of an aircraft have been investigated. Nonlinear functions of pitching-moment and lift coefficients with angle of attack were considered. Analog results of aircraft motions in response to step elevator deflections and to the action of the proportional control systems are presented. The occurrence of continuous hunting oscillations was predicted and demonstrated for the attitude stabilization system with proportional control for certain nonlinear pitching-moment variations and autopilot adjustments.

NACA RM L50L12b

THE EFFECTS OF VARIOUS PARAMETERS INCLUDING MACH NUMBER ON PROPELLER-BLADE FLUTTER WITH EMPHASIS ON STALL FLUTTER. John E. Baker. January 31, 1951. 40p. diagrs., 3 tabs. (NACA RM L50L12b)

The effect of many parameters significant to wing flutter as well as blade twist was studied on several rotating models to determine their significance with respect to propeller stall flutter. The minimum values of the flutter-speed coefficient were found to be slightly greater than 1.0 at subcritical Mach numbers. Of the few parameters that raised the minimum flutter-speed coefficients, forward movement of the section center-of-gravity location and Mach number at supercritical speeds were most significant. The effect of Mach number was of such significance that a tentative criterion for designing completely flutter-free thin supersonic propellers is indicated.

NACA RM L51A10

AN INVESTIGATION OF THE EFFECT OF VERTICAL-FIN LOCATION AND AREA ON LOW-SPEED LATERAL STABILITY DERIVATIVES OF A SEMITAILLESS AIRPLANE MODEL. Lewis R. Fisher and William H. Michael, Jr. March 7, 1951. 41p. diagrs., photos. (NACA RM L51A10)

A low-speed wind-tunnel investigation was conducted in order to determine the effect of vertical-fin location and area on the static and rotary lateral stability derivatives of a semitailless airplane model and to establish the validity of the application of the usual methods for predicting the stability derivatives of such airplanes. Comparisons are made of the experimental and calculated derivatives for the wing and vertical fins wherein consideration is taken of some interference effects.

NACA RM L51A26

INVESTIGATION AT LOW SPEED OF THE EFFECTIVENESS AND HINGE MOMENTS OF A CONSTANT-CHORD AILAVATOR ON A LARGE-SCALE TRIANGULAR WING WITH SECTION MODIFICATION. John G. Hawes and Ralph W. May, Jr. April 24, 1951. 47p. diagrs., photos., tab. (NACA RM L51A26)

Results are presented of an investigation to determine the low-speed longitudinal, lateral, and hinge-moment control characteristics at zero yaw of a large-scale 60° delta wing having a 10-percent-thick biconvex symmetrical airfoil. The wing was also tested with a nose glove having NACA 65-010 section ordinates. The wing was equipped with a constant-chord plain-type semispan ailavator having two segments.

NACA RM L51B09

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF THE EFFECTS OF SYMMETRICAL DEFLECTION OF HALF-DELTA TIP CONTROLS ON THE DAMPING IN ROLL AND YAWING MOMENT DUE TO ROLLING OF A TRIANGULAR-WING MODEL. Walter D. Wolhart. April 6, 1951. 17p. diagrs., photos. (NACA RM L51B09)

Results are presented of a wind-tunnel investigation at low speed to determine the effects of symmetrical deflection of half-delta tip controls on the damping in roll and yawing moment due to rolling of a triangular wing model. The investigation included determination of the effects of control size as well as control deflection.

NACA RM L51D20

LOW-SPEED INVESTIGATION OF SEVERAL TYPES OF SPLIT FLAP ON A 47.7° SWEPTBACK-WING - FUSELAGE COMBINATION OF ASPECT RATIO 5.1 AT A REYNOLDS NUMBER OF 6.0×10^6. Stanley H. Spooner and Ernst F. Mollenberg. July 1951. 41p. diagrs., photo., tab. (NACA RM L51D20)

Results are presented of an investigation to determine the characteristics of a 47.7° sweptback-wing - fuselage combination equipped with split flaps and several modifications thereof. The modifications consisted of extended split (Zap), rotated split, step split, and triangular flaps. The wing had an aspect ratio of 5.1, a taper ratio of 0.383, and NACA 64-210 airfoil sections. The maximum wing thickness in a plane parallel to the plane of symmetry was 7.5 percent of the wing chord. The tests were conducted in the Langley 19-foot pressure tunnel at a Reynolds number of 6.0×10^6 and a Mach number of 0.14.

NACA RM L51D20a

LOW-SPEED STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° TRIANGULAR-WING MODEL HAVING HALF-DELTA TIP CONTROLS. Byron M. Jaquet, M. J. Queijo and Jacob H. Lichtenstein. June 1951. 30p. diagrs., photos. (NACA RM L51D20a)

The results are presented of an investigation to determine the low-speed static longitudinal stability and control-effectiveness characteristics of a 60° triangular-wing model having half-delta tip controls. Comparisons of results are made with constant-chord flaps. Effects of fuselage and end plates on stability and control characteristics are presented. Results are compared with available theory where possible.

NACA RM L51E11a

EFFECTS OF INLET WALL CONTOUR ON THE PRESSURE RECOVERY OF A 10° 10-INCH-INLET-DIAMETER CONICAL DIFFUSER. Martin R. Copp. September 1951. 29p. diagrs., photos. (NACA RM L51E11a)

An investigation was made with a 10° 10-inch-inlet-diameter conical diffuser of 2:1 area ratio to determine the influence on flow characteristics and pressure recovery of sharpness of curvature of the junction between the walls of a conical diffuser and a cylindrical approach tube. The investigation was performed for two thicknesses of inlet boundary layer over a Reynolds number range of 1.2×10^6 to 3.2×10^6 and a mean inlet Mach number range of approximately 0.28 to choking. The over-all static-pressure recovery, expressed as the ratio of the actual rise in static pressure divided by the ideal rise in static pressure, was entirely independent of the inlet wall shape.

NACA RM L51E16

WING-FLOW INVESTIGATION OF A 45° CONE AS AN ANGLE-OF-ATTACK MEASURING DEVICE AT TRANSONIC SPEEDS. Herbert C. McClanahan, Jr. July 1951. 15p. photos., diagrs. (NACA RM L51E16)

A study of pressure measurements on a cone of 45° apex angle made at angles of attack from -10° to 50° and zero yaw angle through a Mach number range of 0.7 to 1.1 to determine the usefulness of a cone for measuring angle of attack at transonic speeds.

NACA RM L51F22

INVESTIGATION OF LOW-SPEED LATERAL CONTROL AND HINGE-MOMENT CHARACTERISTICS OF A 20-PERCENT-CHORD PLAIN AILERON ON A 47.7° SWEPTBACK WING OF ASPECT RATIO 5.1 AT A REYNOLDS NUMBER OF 6.0×10^6. William M. Hadaway and Reino J. Salmi. October 1951. 31p. diagrs. (NACA RM L51F22)

Contains results of wind-tunnel tests to determine the lateral control, hinge-moment, aileron-load, and balance-chamber-pressure characteristics of a 20-percent-chord plain aileron on a 47.7° sweptback wing of aspect ratio 5.1 having NACA 64-210 airfoil sections with and without high-lift and stall-control devices. The investigation was conducted at a Reynolds number of 6.0×10^6 and a corresponding Mach number of 0.14 for an angle-of-attack range of -4° to approximately 30°.

NACA RM L51G30

A COMPARISON OF THE SPANWISE LOADING CALCULATED BY VARIOUS METHODS WITH EXPERIMENTAL LOADINGS OBTAINED ON A 45° SWEPTBACK WING OF ASPECT RATIO 8 AT A REYNOLDS NUMBER OF 4.0×10^6. William C. Schneider. January 1952. 32p. diagrs., tab. (NACA RM L51G30)

Experimental force and moment data obtained by pressure measurements on a wing of aspect ratio 8.02, 45° sweepback of the quarter-chord line, taper ratio of 0.45, and NACA 631A012 airfoil sections parallel to the plane of symmetry have been compared with the calculated loadings obtained by the standard methods proposed by Weissinger, Falkner, and Multhopp, as well as by variations thereof. On the basis of the present calculations, the Weissinger solution, when the number of control points was increased from 7 (the number suggested by Weissinger) to 15, or the Multhopp solution when using at least 15 control points, resulted in a good compromise between lift-curve slope and load shape, although all of the calculations underestimated C_{L_α}.

NACA RM L51H09a

EXPERIMENTAL AND ANALYTICAL INVESTIGATION OF FLUTTER OF A NONUNIFORM SWEPTBACK CANTILEVER WING WITH TWO CONCENTRATED WEIGHTS. John L. Sewall. December 1951. 33p. diagrs., photos., 3 tabs. (NACA RM L51H09a)

An experimental and analytical investigation of the flutter of a weighted cantilever wing, swept back 34.5°, is reported. Concentrated weights which were 78.4 percent and 42.0 percent of the weight of the wing were mounted at approximately one-third and three-quarters of the span respectively, and flutter data obtained for this weighted condition were analyzed by means of a Rayleigh-Ritz type of flutter theory employing uncoupled still-air vibration modes. Unusually good agreement was obtained by using two modes (fundamental bending and fundamental torsion), and the introduction of three and four higher modes did not appreciably affect this agreement. Additional information related to the theory is given in an appendix.

NACA RM L51H15

COMPARISON OF SEMISPAN AND FULL-SPAN TESTS OF A 47.5° SWEPTBACK WING WITH SYMMETRICAL CIRCULAR-ARC SECTIONS AND HAVING DROOPED-NOSE FLAPS, TRAILING-EDGE FLAPS, AND AILERONS. Stanley Lipson and U. Reed Barnett, Jr. December 1951. 60p. photos., diagrs. (NACA RM L51H15)

An investigation was conducted in the Langley full-scale tunnel to determine the comparative characteristics of a full-span and semispan 47.5° sweptback wing having 10-percent thick biconvex airfoil sections and an aspect ratio of 3.5. The configurations tested were the basic wing, the wing with various combinations of leading- and trailing-edge flaps, and the basic wing with an aileron deflected. The results included both force and pressure measurements and were obtained at a Reynolds number of 4.2×10^6 and a Mach number of 0.07.

NACA RM L51H31

PRELIMINARY INVESTIGATION OF THE TRANSFER OF HEAT FROM A FLAT PLATE AT A MACH NUMBER OF 1.5. M. A. Emmons, Jr. and R. F. Blanchard. December 1951. 23p. diagrs., photos. (NACA RM L51H31)

Surface temperatures and heat transfer to the air stream have been measured for turbulent flow over a flat plate at a Mach number of 1.5 and at a Reynolds number, based on the momentum thicknesses of boundary layer, of approximately 5000. Preliminary data are presented and the surface heat-transfer coefficient calculated from these data is considered to be accurate to ±2.6 percent at a temperature potential of 50° F. These data are in good agreement with the results produced by applying modifications obtained from published information to existing subsonic theories.

NACA RM L51I10

LOW-SPEED WIND-TUNNEL INVESTIGATION OF LATERAL CONTROL CHARACTERISTICS OF A 60° TRIANGULAR-WING MODEL HAVING HALF-DELTA TIP CONTROLS. Byron M. Jaquet and M. J. Queijo. November 1951. 50p. diagrs., photos. (NACA RM L51I10)

Results are presented of a low-speed investigation of the lateral control characteristics of a 60° triangular wing model equipped with half-delta tip controls having areas of 5, 10, and 15 percent of the wing area (sum of left- and right-control areas). Effects of end plates are determined for 10-percent-area controls. Half-delta tip controls are compared with constant-chord controls. Experimental control and rolling effectiveness are compared with theory.

NACA RM L51J05

LOW-SPEED INVESTIGATION OF THE EFFECTS OF WING LEADING-EDGE MODIFICATIONS AND SEVERAL OUTBOARD FIN ARRANGEMENTS ON THE STATIC STABILITY CHARACTERISTICS OF A LARGE-SCALE TRIANGULAR WING. H. Clyde McLemore. January 1952. 64p. diagrs., photo., tab. (NACA RM L51J05)

Results are presented of an investigation in the Langley full-scale tunnel to determine the effects of wing leading-edge modifications and several outboard fin arrangements on the low-speed static-stability characteristics of a large-scale triangular wing having 60° of leading-edge sweep and 10-percent-thick circular-arc airfoil sections parallel to the plane of symmetry. The Reynolds number range was from 2.70×10^6 to 9.72×10^6.

NACA RM L51J19

THEORETICAL CALCULATION OF THE EFFECT OF THE FUSELAGE ON THE SPANWISE LIFT DISTRIBUTION ON A WING. Martin Zlotnick and Franklin W. Diederich. March 1952. 27p. diagrs. (NACA RM L51J19)

A method is presented for calculating the effects of the fuselage on the spanwise lift distribution on a wing by an application of a conformal-mapping procedure to the simplified lifting-surface theory. This method is applicable to any symmetrical wing-fuselage configuration. An outline of the computing procedure and a comparison of the calculated results with experimental results are included. A numerical example is given.

NACA RM L51J23

METHOD OF ESTIMATING THE STICK-FIXED LONGITUDINAL STABILITY OF WING-FUSELAGE CONFIGURATIONS HAVING UNSWEPT OR SWEPT WINGS. Milton D. McLaughlin. January 1952. 41p. diagrs., 3 tabs. (NACA RM L51J23)

A method is given for calculating the stick-fixed longitudinal stability of a wing-fuselage configuration at subcritical Mach numbers. The method applies to unswept- and swept-wing configurations. A variation of the additional fuselage loading due to the presence of the wing is presented. A comparison of the calculated neutral points with neutral points obtained from experiment for 23 wing-fuselage configurations is presented.

NACA RM L51J25

ANALYSIS OF V-g RECORDS FROM THE GRUMMAN F8F-2 AIRPLANE. James O. Thornton. July 1952. 11p. diagrs., tab. (NACA RM L51J25)

V-g records obtained in training and operational flights of the F8F-2 airplane are analyzed statistically to show the frequency with which large values of normal acceleration and airspeed are encountered. A comparison is made with previous V-g results from the F8F-1 airplane.

NACA RM L51K09

THE EFFECT OF SURFACE ROUGHNESS ON THE PERFORMANCE OF A 23° CONICAL DIFFUSER AT SUBSONIC MACH NUMBERS. Jerome Persh. January 1952. 42p. diagrs., photos. (NACA RM L51K09)

An investigation was conducted to determine the effect of surface roughness on the performance of a 2:1 area ratio, 23° conical diffuser with a constant-area tail pipe about 3-1/2 inlet diameters in length. The inlet-boundary-layer thickness was of the order of 5 percent of the inlet diameter. The air flows used in this investigation cover an inlet Mach number range from 0.10 to 0.64 corresponding to Reynolds numbers of 10^6 to 6 x 10^6 based on inlet diameter. The surface of the diffuser was coated with cork particles of a controlled size. Incremental bands of roughness were removed from the downstream edge after each series of pressure measurements were made and the variation of diffuser performance with percent of diffuser length roughened thereby determined.

NACA RM L51K26

FORCE AND PRESSURE INVESTIGATION AT LARGE SCALE OF A 49° SWEPTBACK SEMISPAN WING HAVING NACA 65A006 SECTIONS AND EQUIPPED WITH VARIOUS SLAT ARRANGEMENTS. Stanley Lipson and U. Reed Barnett, Jr. January 1952. 60p. diagrs., photo., tab. (NACA RM L51K26)

The effects of slat span and slat deflection angle on the longitudinal aerodynamic characteristics of a semispan 49.1° sweptback wing, aspect ratio 3.78, having NACA 65A006 airfoil sections have been investigated in the Langley full-scale tunnel. Normal-force measurements were obtained on the extended slat, both with and without a trailing-edge flap deflected. The greater part of the data was obtained at a Reynolds number of 6.1 x 10^6 and a Mach number of 0.10.

NACA RM L51L12

STUDIES OF THE FLOW FIELD BEHIND A LARGE SCALE 47.5° SWEPTBACK WING HAVING CIRCULAR-ARC AIRFOIL SECTIONS AND EQUIPPED WITH DROOPED-NOSE AND PLAIN FLAPS. Roy H. Lange and Marvin P. Fink. March 1952. 57p. diagrs., photos., tab. (NACA RM L51L12)

Results are presented of an investigation at large scale of the downwash, sidewash, and wake characteristics behind a 47.5° sweptback wing having circular-arc airfoil sections and with drooped-nose and plain flaps neutral and deflected 40°. The surveys were made at a Reynolds number of 4.3 x 10^6 and a Mach number of 0.07 and are presented for three longitudinal distances behind the wing. Comparisons are made between the downwash calculated by using experimental span loadings and the experimental downwash obtained.

NACA RM L52C17

A STUDY OF THE CHARACTERISTICS OF HUMAN-PILOT CONTROL RESPONSE TO SIMULATED AIRCRAFT LATERAL MOTIONS. Donald C. Cheatham. May 1952. 39p. diagrs., photos., tab. (NACA RM L52C17)

There are presented studies of the characteristics of pilot ability to control dynamically unstable yawing oscillations, studies of pilot control response to simulated aircraft yawing motions, and studies of the feasibility of representing pilot control response in an analytical form.

NACA RM L52C20

A PRELIMINARY GUST-TUNNEL INVESTIGATION OF LEADING-EDGE SEPARATION ON SWEPT WINGS. George L. Cahen. June 1952. 12p. photos. (NACA RM L52C20)

The results of a series of qualitative studies with tufts on three wings having sweepback angles of 30°, 45°, and 60° show that under certain conditions a leading-edge vortex can exist in the unsteady flow associated with a gust. It was indicated that, if a wing in steady flight prior to entering a gust is at an angle of attack several degrees less than that at which vortex flow first begins in steady flow, it may penetrate the gust without having the vortex develop, even if its angle of attack is increased by the gust into the vortex-flow regime. However, if the wing is within the vortex-flow regime prior to entering a gust, the vortex flow can progress rapidly.

NACA RM L52D04

LOW-SPEED WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF PROPELLER OPERATION AT HIGH THRUST ON THE LONGITUDINAL STABILITY AND TRIM OF A TWIN-ENGINE AIRPLANE CONFIGURATION. William C. Sleeman, Jr. and Edward L. Linsley. July 1952. 66p. diagrs., photos. (NACA RM L52D04)

An investigation was made to determine the effects of dual-rotation propeller operation at high thrust on the static longitudinal stability characteristics of a semispan powered model representing a twin-engine airplane configuration with flaps retracted. The flow field behind the model was studied extensively by several techniques. Dynamic pressure ratios and effective downwash angles were obtained for a wide range of tail heights and the general flow angularity behind the model was obtained by the tuft-grid technique. Effects of extreme power on longitudinal stability were evaluated for several combinations of horizontal tail height and vertical location of the center of gravity.

NACA RM L52D17a

EFFECTS OF SEVERAL HIGH-LIFT AND STALL-CONTROL DEVICES ON THE AERODYNAMIC CHARACTERISTICS OF A SEMISPAN 49° SWEPT-BACK WING. U. Reed Barnett, Jr. and Stanley Lipson. September 1952. 39p. diagrs., photo. (NACA RM L52D17a)

Tests were conducted in the Langley full-scale tunnel of a wing with 49.1° sweepback of the leading edge, aspect ratio 3.78, and NACA 65A006 sections streamwise to determine the effect of a leading-edge flap, a slat, and a plain trailing-edge flap on the aerodynamic characteristics of a wing. Limited tests were also conducted concerning boundary-layer control by suction and blowing. Rolling moments due to a flap-type aileron were also measured. Most of the data were obtained at a Reynolds number of 6.1×10^6 and a Mach number of 0.10.

NACA RM L52D25a

EXPERIMENTAL INVESTIGATION OF FLOW THROUGH THREE HIGHLY LOADED INLET GUIDE VANES HAVING DIFFERENT SPANWISE CIRCULATION GRADIENTS. Loren A. Beatty, Melvyn Savage and James C. Emery. July 1952. 24p. diagrs., tab. (NACA RM L52D25a)

Three highly loaded axial-flow compressor inlet guide vanes with a free vortex and solid body design were designed and tested in a low-speed annular cascade. A comparison between design and measured turning angles was made by both neglecting and taking into account the secondary flow effects. Contour plots of total pressure loss across the guide vane were made. When the radial gradient of circulation was large (the hub axial velocity two or three times greater than that at the tip), actual turning angles were several degrees below design over the outboard 30 percent of the vane. For such guide vanes, the Lieblein and Ackley method for correcting design two-dimensional turning angles by taking into account secondary flows provided fairly good agreement between design and measured turning angles.

NACA RM L52H19

INVESTIGATION AT LOW SPEED OF THE DOWNWASH, SIDEWASH, AND WAKE CHARACTERISTICS BEHIND A LARGE-SCALE TRIANGULAR WING, INCLUDING THE EFFECTS OF YAW, FULL-SPAN TRAILING-EDGE FLAPS, AND TWO LEADING-EDGE MODIFICATIONS. Edward F. Whittle, Jr. and John G. Hawes. October 1952. 65p. diagrs., photos., tab. (NACA RM L52H19)

Results are presented of a low-speed investigation of the downwash, sidewash, and wake characteristics in three planes behind a large-scale 60° triangular wing. Included are the effects of yawing 10°, full-span plain flaps deflected 20°, and two leading-edge nose-glove modifications. Calculations of the static longitudinal stability and trim characteristics of an assumed 60° triangular-wing airplane configuration showing the effect of three tail areas, two longitudinal positions, and various vertical positions are also presented.

NACA RM L52I24

SOME LOW-SPEED STUDIES OF THE EFFECTS OF WING LOCATION ON WING-DEFORMATION-BODY-FREEDOM FLUTTER. E. Widmayer, Jr. November 1952. 21p. diagrs., 3 tabs. (NACA RM L52I24)

Some flutter experiments on unswept wings and 45° swept wings involving wing deformation and fuselage mobility in pitch and performed at low air speeds have been reported. The flutter was obtained for a range of wing locations rearward of the pitching axis and was characterized by low values of reduced frequency. An analysis of the flutter has been made, the flutter being calculated for several approximations to the aerodynamic forces. A comparison of the results of the calculations with the results of the experiments indicates that some accounting of the effect of aspect ratio on the aerodynamic forces is needed to adequately predict the flutter. The experiments using the 45° swept wings yielded no flutter for the range of wing locations and fuselage inertias examined.

NACA RM L52J06

A CASCADE - GENERAL-MOMENTUM THEORY OF OPERATION OF A SUPERSONIC PROPELLER ANNULUS. Bernard B. Klawans and Arthur W. Vogeley. January 1953. 25p. diagrs., 2 tabs. (NACA RM L52J06)

A cascade--general-momentum-theory method for calculating the operating conditions of a supersonic propeller annulus throughout the flight Mach number range is presented. Representative subsonic, transonic, and supersonic solutions are given. The method permits consideration of drag due to lift and thickness, shock interference, and solidity and appears useful in studying the general trends of supersonic propeller operation.

NACA RM L52L30a

SUMMARY OF PILOTS' REPORTS OF CLEAR-AIR TURBULENCE AT ALTITUDES ABOVE 10,000 FEET. Harry Press, Martin H. Schindler and James K. Thompson. March 1953. 18p. diagrs., 5 tabs. (NACA RM L52L30a)

A cooperative program for the collection of pilots' reports of clear-air turbulence encountered at high altitudes in normal civil and military operations was undertaken in 1949. A simple postal-card questionnaire was distributed to groups of civil aircraft operators and selected military units, and a summary of the data obtained from this survey is presented together with some additional reports from Air Weather Service reconnaissance flights.

NACA RM L53A29

LOW-SPEED LATERAL CONTROL CHARACTERISTICS OF AN UNSWEPT WING WITH HEXAGONAL AIRFOIL SECTIONS AND ASPECT RATIO 4.0 AT A REYNOLDS NUMBER OF 6.2×10^6. William M. Hadaway. March 1953. 24p. diagrs., photo. (NACA RM L53A29)

Results of wind-tunnel tests to determine the lateral control, hinge moment, aileron load, and aileron balance chamber pressure characteristics of both a 0.79b/2 and 0.40b/2 outboard 25-percent-chord aileron on a hexagonal 6-percent-thick wing of aspect ratio 4.0 and taper ratio 0.625 are presented. Tests were made at a Reynolds number of 6.2×10^6 and a Mach number of 0.15 with a fuselage attached to the wing. Effects of deflection of leading- and trailing-edge flaps on the aileron characteristics of the outboard aileron were also investigated.

NACA RM L53D09

LOW-SPEED, LARGE-SCALE INVESTIGATION OF AERODYNAMIC CHARACTERISTICS OF A SEMISPAN 49° SWEPTBACK WING WITH A FOWLER FLAP IN COMBINATION WITH A PLAIN FLAP, SLATS, AND FENCES. Edward F. Whittle, Jr. and Stanley Lipson. June 1953. 42p. diagrs., photos., tab. (NACA RM L53D09)

Tests were made in the Langley full-scale tunnel to determine the effect of a Fowler flap on the aerodynamic characteristics of a semispan 49.1° swept-back wing having NACA 65A006 airfoil sections, an aspect ratio of 3.78, and a taper ratio of 0.59. Slats, fences, and a plain flap were tested in combination with the Fowler flap, which was located near the trailing edge of the plain flap. The tests were conducted at Reynolds numbers of 6.1×10^6 and 4.4×10^6 with corresponding Mach numbers of 0.10 and 0.07, respectively.

NACA RM L53E01a

MOMENT OF INERTIA AND DAMPING OF FLUID IN TANKS UNDERGOING PITCHING OSCILLATIONS. Edward Widmayer, Jr. and James R. Reese. June 1953. 9p. diagrs. (NACA RM L53E01a)

Studies were made of the fluid dynamics of some different-shaped fuel tanks considered as being in a horizontal flight attitude and undergoing pitching oscillations of a few degrees. For the tank-full case, comparisons of the experimental moment of inertia of the fluid with some theoretical inertia solutions for tanks having elliptic and rectangular sections were made. In the partially full case the experimentally measured inertias were compared with the solid inertias for the same tank fullness with the view of referring the partially full case to the theoretical solutions for the tank-full condition. Studies of the effective fluid damping indicated that for decaying oscillations the damping is nonlinear with amplitude. For steady oscillations, the damping was large as compared with the initial values for decaying oscillations and tended to increase with increasing frequency and amplitude.

NACA RM L53E06b

AN EXPERIMENTAL INVESTIGATION OF WHEEL SPIN-UP DRAG LOADS. Benjamin Milwitzky, Dean C. Lindquist and Dexter M. Potter. June 1953. 18p. diagrs. (NACA RM L53E06b)

This paper presents some recently obtained information on landing-gear applied drag loads and on the nature of the wheel spin-up phenomenon in landing, based on a program of tests under controlled conditions in the Langley impact basin. In particular, a study has been made of the nature and variation of the coefficient of friction between the tire and the runway during the spin-up process. Also, comparisons have been made of the various results obtained in forward-speed impacts, forward-speed impacts with reverse wheel rotation, spin-up drop tests, and forward-speed impacts with wheel prerotation.

NACA RM L53E14a

A FLIGHT INVESTIGATION OF SOME EFFECTS OF AUTOMATIC CONTROL ON GUST LOADS. Chester B. Payne. July 1953. 18p. diagrs., tab. (NACA RM L53E14a)

The results of a limited flight investigation with a transport airplane to determine the effects of automatic control on gust loads indicate that the loads experienced by the test airplane when automatically controlled were less than those without automatic control. The magnitude of the difference between the loads with and without automatic control was roughly 7 percent. There was no apparent change in the effect of the autopilot on gust loads for a small increase in autopilot sensitivity.

NACA RM L53F12

THE CALCULATED AND EXPERIMENTAL INCREMENTAL LOADS AND MOMENTS PRODUCED BY SPLIT FLAPS OF VARIOUS SPANS AND SPANWISE LOCATIONS ON A 45° SWEPTBACK WING OF ASPECT RATIO 8. H. Neale Kelly. September 1953. 35p. diagrs., photo. (NACA RM L53F12)

Experimental data on the incremental lift and pitching moment produced in the linear angle-of-attack range by 20-percent-chord split flaps of various spans and positions on two 45° sweptback wings of aspect ratio 8.02 have been obtained at a Reynolds number of 4,000,000 and a Mach number of 0.19 by pressure-distribution tests in the Langley 19-foot pressure tunnel. The experimental data have been compared with calculated increments in span loading and pitching moment, and the probable causes of the deviations of the calculated values from the experimental are discussed.

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM RESTRICTED TO UNCLASSIFIED, 12/14/53.

NACA RM A8A21

THE EFFECTIVENESS AT HIGH SPEEDS OF A 10-PERCENT-CHORD PLAIN TRAILING-EDGE FLAP ON THE NACA 65-210 AIRFOIL SECTION. Richard J. Ilk. June 14, 1948. 26p. diagrs., tab. (NACA RM A8A21)

This report contains the results of a high-speed wind-tunnel investigation of the effectiveness of a 10-percent-chord plain flap on the NACA 65-210 airfoil section. The results include an indication of the lift-producing characteristics and the effectiveness of the 10-percent-chord flap. From a comparison of the characteristics of the 10-percent-chord flap with those of a 20-percent-chord flap, it was concluded that, although a reduction in flap-chord ratio from 0.20 to 0.10 lessens the severity of the effectiveness loss at supercritical speeds, the 20-percent-chord flap is more effective throughout the entire range of Mach numbers from 0.3 to 0.875.

NACA RM A8D07

INVESTIGATION OF A THIN WING OF ASPECT RATIO 4 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. I - CHARACTERISTICS OF A PLAIN WING. Ben H. Johnson, Jr. June 2, 1948. 37p. diagrs., photo. (NACA RM A8D07)

This report presents results of tests of a semispan model of an unswept wing having an aspect ratio of 4, a taper ratio of 0.5, and a 4.5-percent-thick diamond profile. The effects of rounding the profile ridge were also investigated. The Reynolds number was varied from 2,000,000 to 10,190,000 at 0.20 Mach number, and the Mach Number was varied from 0.20 to 0.94 at Reynolds numbers below 3,000,000. No excessive movement of the aerodynamic center was observed up to a Mach number of 0.94. The boundary layer separated near the ridge at low Reynolds numbers, but rounding the ridge diminished this separation, increased the lift-drag ratio, and decreased the minimum drag.

NACA RM A8D20

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. SUBSONIC MACH AND REYNOLDS NUMBER EFFECTS ON THE CHARACTERISTICS OF THE WING AND ON THE EFFECTIVENESS OF AN ELEVON. Robert M. Reynolds and Donald W. Smith. October 11, 1948. 56p. diagrs., photos., tab. (NACA RM A8D20)

This report presents results of tests of a semispan model of a wing having its leading edge swept back 63°, an aspect ratio of 3.5, a taper ratio of 0.25, zero twist, and the NACA 64A006 profile parallel to the airstream. The effectiveness of an elevon as a longitudinal control was investigated. Aerodynamic characteristics of the model are presented for a range of Mach numbers from 0.18 to 0.925 at Reynolds numbers of 2.35 to 3.55 million and for a range of Reynolds numbers from 2.35 to 10 million at 0.18 Mach number.

NACA RM A8E21

TESTS OF A TRIANGULAR WING OF ASPECT RATIO 2 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. III - THE EFFECTIVENESS AND HINGE MOMENTS OF A SKEWED WING-TIP FLAP. Carl D. Kolbe and Bruce E. Tinling. September 21, 1948. 30p. diagrs., photo. (NACA RM A8E21)

Results of wind-tunnel tests of a semispan model of a triangular wing of aspect ratio 2 with a skewed wing-tip flap are presented. Lift, drag, pitching-moment, and hinge-moment data are included for subsonic Mach numbers up to 0.95. The flap showed extremely high hinge moments and low effectiveness as a longitudinal control. Although less affected by compressibility, this flap is indicated to be inferior to a constant-chord flap when applied to this triangular wing.

NACA RM A8F15

INVESTIGATION OF A THIN WING OF ASPECT RATIO 4 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. II - THE EFFECT OF CONSTANT-CHORD LEADING- AND TRAILING-EDGE FLAPS ON THE LOW-SPEED CHARACTERISTICS OF THE WING. Ben H. Johnson, Jr. and Angelo Bandettini. October 18, 1948. 42p. diagrs., photos., tabs. (NACA RM A8F15)

Results of tests at low speeds of a thin unswept wing equipped with a constant-chord leading-edge plain flap and a constant-chord trailing-edge flap of either the plain or split type are presented at Reynolds numbers from 3,000,000 to 10,000,000. The maximum lift coefficient obtained by an optimum deflection of these flaps in combination was 1.45 compared to 0.74 for the plain wing with all flaps neutral.

NACA RM A8K19

INVESTIGATION OF A THIN WING OF ASPECT RATIO 4 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. IV - THE EFFECT OF A CONSTANT-CHORD LEADING-EDGE FLAP AT HIGH SUBSONIC SPEEDS. Ben H. Johnson, Jr. and Verlin D. Reed. January 20, 1949. 30p. diagrs., photo. (NACA RM A8K19)

The report presents results of tests at Mach numbers from 0.20 to 0.94 of a thin straight wing of aspect ratio 4, having a full-span, constant-chord, leading-edge flap. The wing profile was a modified diamond having a thickness ratio of 0.042. The investigation was made at a constant Reynolds number of 2,000,000. Deflection of the leading-edge flap produced an increase in maximum lift-drag ratio and an increase in the lift coefficient for maximum lift-drag ratio for all Mach numbers below 0.94. At a Mach number of 0.94, deflection of the flap resulted in a decrease of the maximum lift-drag ratio.

NACA RM A8L20

INVESTIGATION OF A THIN STRAIGHT WING OF ASPECT RATIO 4 BY THE NACA WING-FLOW METHOD. LIFT AND PITCHING-MOMENT CHARACTERISTICS OF THE WING ALONE. George A. Rathert, Jr., Carl M. Hanson and L. Stewart Rolls. February 14, 1949. 37p. diagrs., photos. (NACA RM A8L20)

This report presents measurements of the lift and pitching-moment characteristics of a straight wing of aspect ratio 4, taper ratio 0.5, having a symmetrical double-wedge airfoil section with a maximum thickness of 4.4-percent chord. The tests were conducted in the Mach number range 0.51 to 1.20, Reynolds numbers 380,000 to 660,000, by the NACA wing-flow method. The results are compared with theory and with wind-tunnel tests of a similar model. It is indicated that in the Mach number range 0.82 to 1.00 the model surface, profile, and test Reynolds number all would be very important considerations in any attempt to study or predict full-scale characteristics from small-model tests.

NACA RM A9A24

A PRELIMINARY EXPERIMENTAL INVESTIGATION OF A SUBMERGED CASCADE INLET. R. Duane Christiani and Lauros M. Randall. March 25, 1949. 29p. diagrs., photos., 3 tabs. (NACA RM A9A24)

Results are presented of an experimental investigation of a submerged air inlet incorporating a cascade of airfoils for turning and diffusing the entering air. The geometric variables investigated included ramp plan form, ramp angle, cascade-axis angle, cascade-blade angle, solidity ratio, and the angle of the duct center line aft of the cascade of airfoils. The effects of these variables on the ram-pressure recoveries for the inlet are shown.

NACA RM A9B28

WIND-TUNNEL INVESTIGATION OF TRANSONIC AILERON FLUTTER. Albert L. Erickson and Robert L. Mannes. June 9, 1949. 55p. diagrs., photos., tab. (NACA RM A9B28)

A new type of aileron flutter is shown to exist in the transonic speed range. This flutter is characterized by the fact that only one degree of mechanical freedom is required.

NACA RM A9D08

A FLIGHT INVESTIGATION OF THE EFFECT OF FLAP DEFLECTION ON HIGH-SPEED LONGITUDINAL-CONTROL CHARACTERISTICS. Maurice D. White, Melvin Sadoff, Lawrence A. Clousing and George E. Cooper. June 30, 1949. 28p. diagrs., photos., tab. (NACA RM A9D08)

Flight tests were conducted on two airplanes to study the effect of wing flap deflection on longitudinal stability and control characteristics at supercritical speeds. Negative flap deflection was beneficial in one case but not in the other. The relative effects on longitudinal stability and control of the variation with Mach number of angle of attack, airplane tail-off pitching moment, downwash and dynamic pressure at the tail, and aileron floating angle are presented. Attempts to predict the supercritical characteristics resulting from deflecting the flaps were made, but the results were inconsistent.

NACA RM A9G20

A PRELIMINARY INVESTIGATION OF THE USEFULNESS OF CAMBER IN OBTAINING FAVORABLE AIRFOIL-SECTION DRAG CHARACTERISTICS AT SUPERCRITICAL SPEEDS. Gerald E. Nitzberg, Stewart M. Crandall and Perry P. Polentz. October 7, 1949. 24p. diagrs. (NACA RM A9G20)

The possibility of employing camber to obtain an airfoil section which, at moderate lift coefficients and supercritical speeds, has drag coefficients significantly lower than those of the corresponding uncambered section is demonstrated. The measured high-speed section characteristics of an example, which appeared promising on the basis of calculations of drag-divergence Mach number, are presented.

NACA RM A9J26

THE EFFECT OF ACCELERATING A HYPOTHETICAL AIRCRAFT THROUGH THE TRANSONIC RANGE WITH CONTROLS FIXED. Howard F. Matthews. April 4, 1950. 30p. diagrs., tab. (NACA RM A9J26)

Mach number histories of the motion experienced by a hypothetical, small, straight-wing aircraft in accelerating at various rates through an assumed controls-fixed pitch-down balance change in the transonic range obtained by a differential analyzer are presented. The effect of longitudinal acceleration on the maximum change in normal acceleration is discussed. It is shown that the Mach number variation of the angle of attack for static balance determines to a great extent the degree of the effect of longitudinal acceleration on the normal acceleration. Two approximate analytical solutions of the longitudinal equations of motion are developed and are shown to compare favorably with the differential-analyzer solutions.

NACA RM A9K01

AN ANALYSIS OF THE FORCES AND PRESSURE DISTRIBUTION ON A WING WITH THE LEADING EDGE SWEPT BACK 37.25°. George G. Edwards and Frederick W. Boltz. March 30, 1950. 102p. diagrs., photos., 2 tabs. (NACA RM A9K01)

Results of wind-tunnel tests are presented for a semi-span model of a wing having the leading edge swept back 37.25°, aspect ratio 6, taper ratio 0.5, zero twist, and NACA 64_1-212 sections normal to the quarter-chord line of these sections. Lift, drag, pitching moment, and pressure-distribution data were obtained for a range of Mach numbers from 0.18 to 0.94, at a Reynolds number of 2,000,000. Similar data were obtained for Reynolds numbers of 1,100,000, 3,000,000, and with roughness applied to the wing (at a Reynolds number of 2,000,000). An analysis is made to correlate the changes in pressure distribution over the wing with the changes in the total forces.

NACA RM E8A27

ICE PROTECTION OF TURBOJET ENGINES BY INERTIA SEPARATION OF WATER. I - ALTERNATE-DUCT SYSTEM. Uwe von Glahn. May 28, 1948. 77p. diagrs., photos., 3 tabs. (NACA RM E8A27)

Aerodynamic and icing investigations of internal water-inertia separation inlets designed to prevent automatically entrance of large quantities of water into a turbojet engine in icing conditions was conducted on a one-half scale model. A simplified analytical approach to the design of internal water-inertia separation inlets is included. Results show that in order to be effective in preventing screen and guide-vane icing for an inlet of this type, a ram-pressure recovery of 75 percent was attained at design inlet-velocity ratio in an icing condition. For nonicing operation, ram-pressure recovery is comparable to direct-ram inlet.

NACA RM E8A28

ICE PROTECTION OF TURBOJET ENGINES BY INERTIA SEPARATION OF WATER. II - SINGLE-OFFSET-DUCT SYSTEM. Uwe von Glahn. June 8, 1948. 11p. diagrs., photos. (NACA RM E8A28)

Investigation of a single-offset-duct system designed to prevent entrance of water into a turbojet engine was conducted on a half-scale nacelle model. An investigation was made to determine ram-pressure recovery and radial velocity profiles at the compressor section and icing characteristics of such a duct system. At a design inlet velocity of 0.77, the maximum ram-pressure recovery attained with effective water-separating inlet was 77 percent, which is considerably less than attainable with a direct-ram inlet. Continuous heating of the accessory-housing surface would be required for inlets that have a small ice storage space.

NACA RM E8A29

ICE PROTECTION OF TURBOJET ENGINES BY INERTIA SEPARATION OF WATER. III - ANNULAR SUBMERGED INLETS. Uwe von Glahn. June 8, 1948. 21p. diagrs., photos., tab. (NACA RM E8A29)

Aerodynamic and icing studies were conducted on a one-half-scale model of an annular submerged inlet for use with axial-flow turbojet engines. Pressure recoveries, screen radial-velocity profiles, circumferential mass-flow variations, and icing characteristics were determined at the compressor inlet. In order to be effective in maintaining water-free induction air, the inlet gap must be extremely small and ram-pressure recoveries consequently are low, the highest achieved being 65 percent at inlet-velocity ratio of 0.86. All inlets exhibited considerable screen icing. Severe mass-flow shifts occurred at angles of attack.

NACA RM E8B27

ANALYSIS OF PARAMETERS FOR THRUST CONTROL OF A TURBOJET ENGINE EQUIPPED WITH AIR-INLET THROTTLE AND VARIABLE-AREA EXHAUST NOZZLE. Aaron S. Boksenbom and Melvin S. Feder. August 10, 1948. 62p. diagrs. (NACA RM E8B27)

By means of an analysis developed in this report, characteristics of a typical turbojet engine equipped with an air-inlet throttle, a variable-area exhaust nozzle, or with a combination of the two were predicted and control-parameter curves were chosen from which such control systems can be designed. The thrust control characteristics of a turbojet engine could be substantially improved by the addition to the conventional control system of either an air-inlet throttle, a variable-area exhaust nozzle, or a combination of the two.

NACA RM E8C09

EFFECT OF INLET-AIR PARAMETERS ON COMBUSTION LIMIT AND FLAME LENGTH IN 8-INCH DIAMETER RAM-JET COMBUSTION CHAMBER. A. J. Cervenka and R. C. Miller. July 22, 1948. 24p. diagrs. (NACA RM E8C09)

The effect of inlet-air parameters on combustion limit and flame length was determined for an 8-inch-diameter ram-jet combustion chamber. For a given combustion-chamber length, combustion efficiency increased with increasing inlet-air temperature or decreasing inlet-air velocity and pressure. Flame length increased with increasing fuel-air ratio, inlet-air pressure, inlet-air velocity, and decreasing inlet-air temperature.

NACA RM E8C18

PRELIMINARY RESULTS OF NATURAL ICING OF AN AXIAL-FLOW TURBOJET ENGINE. Loren W. Acker. August 6, 1948. 16p. diagrs., photos. (NACA RM E8C18)

A flight investigation in natural icing conditions was conducted to determine effect of ice formations on performance of an axial-flow turbojet engine. Re-

sults are presented for a flight in which the icing rate varied from 5.1 to 2.1 inches per hour. During 45 minutes in icing, tail-pipe temperature increased from 761° to 1065° F and jet thrust decreased from 1234 to 910 pounds. Ice penetrated to the second-stage stator blades.

NACA RM E8D13

EXPERIMENTAL INVESTIGATION OF HOT-GAS BLEEDBACK FOR ICE PROTECTION OF TURBO-JET ENGINES. I - NACELLE WITH OFFSET AIR INLET. Edmund E. Callaghan, Robert S. Ruggeri and Richard P. Krebs. July 9, 1948. 22p. diagrs. (NACA RM E8D13)

Investigations were conducted on a two-thirds-scale model of a turbojet-engine nacelle to provide icing protection for the engine, protective screen, and accessory housing by the introduction of hot gases into the inlet-air stream. The hot gas was injected into the inlet-air stream from a series of orifice holes around the inlet. Results indicate that if a minimum kinetic temperature of 32° F is maintained throughout the screen, adequate ice protection will be obtained for the entire installation.

NACA RM E8F01a

NATURAL ICING OF AN AXIAL-FLOW TURBOJET ENGINE IN FLIGHT FOR A SINGLE ICING CONDITION. Loren W. Acker. August 12, 1948. 16p. diagrs., photos. (NACA RM E8F01a)

A flight investigation in natural icing conditions was conducted to determine the effect of ice formations on performance of axial-flow turbojet engines. Results are presented for a flight in which liquid-water content varied from 0.077 to 0.490 gram per cubic meter. During 60 minutes in icing, tail-pipe temperature increased from 865° to 965° F and the jet thrust decreased from 1950 to 1700 pounds. The engine was satisfactorily accelerated to take-off power near the end of the icing period.

NACA RM E8J25b

ANALYSIS OF EFFECTS OF INLET PRESSURE LOSSES ON PERFORMANCE OF AXIAL-FLOW TYPE TURBOJET ENGINE. Newell D. Sanders and John Palasics. November 24, 1948. 39p. diagrs. (NACA RM E8J25b)

The effects of inlet pressure losses on the net thrust and specific fuel consumption for an axial-flow type turbojet engine have been determined. At low altitudes and flight Mach numbers, a 10-percent loss in inlet total pressure will result in a 14-percent loss in net thrust and a 15-percent increase in specific fuel consumption, and at high altitudes and flight Mach numbers a 10-percent inlet total-pressure loss produces a 22-percent loss in net thrust and an increase of 16 percent in specific fuel consumption.

NACA RM E8J25c

INLET ICING AND EFFECTIVENESS OF HOT-GAS BLEEDBACK FOR ICE PROTECTION OF TURBO-JET ENGINE. William A. Fleming and Martin J. Saari. November 26, 1948. 37p. diagrs., photos. (NACA RM E8J25c)

A method of protecting the inlet of a turbojet engine from ice was studied in the NACA Cleveland altitude wind tunnel whereby hot gas was bled from the turbine inlet and injected into the induction system ahead of the compressor. At ambient-air temperatures of 25° to 30° F, the hot-gas bleedback system removed ice from the compressor inlet in 3 to 5 minutes; however, at ambient temperatures of about 0° F, ice formed on the compressor inlet very slowly below 11,000 rpm with the hot-gas bleedback system in operation.

NACA RM E9B23

EFFECT OF HOT-GAS BLEEDBACK ICE PREVENTION ON PERFORMANCE OF A TURBOJET ENGINE WITH FIXED-AREA TAIL-PIPE NOZZLE. Robert O. Dietz, Jr. and Richard P. Krebs. May 16, 1949. 26p. diagrs. (NACA RM E9B23)

An analytical investigation was conducted to show that the inlet of a turbojet engine can be protected from ice accretions by bleeding hot gases from other locations within the engine to the inlet without undue loss in thrust. Bleedback from the combustion chamber was preferable to tail-pipe bleedback because the pressure was greater, less bleedback was required, and smaller thrust losses resulted. The thrust available at take-off from an engine protected against icing conditions in temperatures as low as -40° F with liquid-water contents as high as 2.5 grams per cubic meter exceeded the thrust available from the same engine in an ambient-air temperature of 100° F.

NACA RM E9C16

EXPERIMENTAL INVESTIGATION OF HOT-GAS BLEEDBACK FOR ICE PROTECTION OF TURBO-JET ENGINES. II - NACELLE WITH LONG STRAIGHT AIR INLET. Edmund E. Callaghan and Robert S. Ruggeri. May 26, 1949. 34p. diagrs., photo. (NACA RM E9C16)

Investigations were conducted on a two-thirds-scale model of a turbojet-engine nacelle to provide basic design criterions for hot-gas bleedback systems. The hot gas was injected into the inlet-air stream from a series of orifices around the inlet. General rules for obtaining a satisfactory orifice configuration are presented. Satisfactory agreement between calculated and measured heat requirements was obtained.

NACA RM E9E06

ANALYSIS AND PRELIMINARY INVESTIGATION OF EDDY-CURRENT HEATING FOR ICING PROTECTION OF AXIAL-FLOW-COMPRESSOR BLADES. Thomas Dallas and C. Ellisman. August 8, 1949. 66p. diagrs., photos., tab. (NACA RM E9E06)

An analysis and a preliminary experimental investigation of the use of eddy currents for heating the blades of an axial-flow compressor of a turbojet engine as a means of ice protection is presented. Steinmetz's analysis of eddy currents in flat plates is extended and formulas are derived that permit calculations of currents, voltages, flux distribution, and power when operation is not limited to conditions of constant permeability. The application of eddy-current heating appears to be feasible for the generation of power densities required for icing protection of axial-flow-compressor blades.

NACA RM E9E12

EXPERIMENTAL INVESTIGATION OF HOT-GAS BLEEDBACK FOR ICE PROTECTION OF TURBOJET ENGINES. III - NACELLE WITH SHORT STRAIGHT AIR INLET. Robert S. Ruggeri and Edmund E. Callaghan. August 4, 1949. 24p. diagrs., photo. (NACA RM E9E12)

An aerodynamic and icing investigation was conducted on a two-thirds-scale model of a turbojet-engine nacelle utilizing a hot-gas bleedback system for ice prevention. The optimum temperature distribution inside the model was obtained at a bleedback of 4.9 percent for a gas temperature of 1000° F and was independent of tunnel velocity. Icing protection for the accessory housing could not be attained at bleedbacks less than 6.0 percent for a gas temperature of 1000° F. Satisfactory agreement between measured and calculated heat requirements for icing conditions was obtained.

NACA RM E9I27

ALTITUDE-CHAMBER PERFORMANCE OF BRITISH ROLLS-ROYCE NENE II ENGINE. II - 18.41-INCH-DIAMETER JET NOZZLE. J. C. Armstrong, H. D. Wilsted and K. R. Vincent. October 26, 1949. 55p. diagrs., 2 tabs. (NACA RM E9I27)

An altitude-chamber investigation of British Rolls-Royce Nene II turbojet engine was conducted over range of altitudes from sea level to 60,000 feet and ram-pressure ratios from 1.00 to 3.50, using 18.41-inch-diameter jet nozzle. The 18.41-inch-diameter jet nozzle showed a small decrease in net-thrust specific fuel consumption from the standard 18.75-inch-diameter jet nozzle at cruise conditions.

NACA RM E9K25a

TRANSIENT OPERATING CHARACTERISTICS OF A TURBOJET ENGINE WHEN SUBJECTED TO STEP CHANGES IN FUEL FLOW. Arthur H. Bell and J. Elmo Farmer. February 20, 1950. 45p. diagrs., photos., 2 tabs. (NACA RM E9K25a)

An investigation was conducted on a typical centrifugal compressor type turbojet engine to determine operating characteristics during changes in engine speed resulting from approximate step changes in fuel flow. The data show the variation with time of engine speed, thrust, fuel flow, and critical gas and material temperatures as caused by sudden changes in fuel flow. Results show that the gas temperature at the tail-cone exit indicated the approximate turbine blade temperature during periods of acceleration and deceleration and that the time required for rotor speed to reach equilibrium was approximately the same for accelerations and decelerations of the same magnitude for the same range of speeds.

NACA RM L8A30a

A COMPILATION OF THE PRESSURES MEASURED ON A WING AND AILERON WITH VARIOUS AMOUNTS OF SWEEP IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Richard T. Whitcomb. April 13, 1948. 84p. diagrs., 78 tabs. (NACA RM L8A30a)

A compilation is made in tabular form of all the pressures measured on a thin high-aspect-ratio wing and aileron with no sweep and with 30° and 45° of sweepback and sweepforward at high subsonic Mach numbers in the Langley 8-foot high-speed tunnel.

NACA RM L8C11

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS AT TRANSONIC SPEEDS OF A SEMISPAN AIRPLANE MODEL HAVING A 45° SWEPTBACK WING AND TAIL AS OBTAINED BY THE TRANSONIC-BUMP METHOD. M. Leroy Spearman. June 30, 1948. 21p. diagrs., photo., tab. (NACA RM L8C11)

Tests were made using the transonic-bump method to determine the stability and control characteristics in the transonic range of a semispan airplane model having a 45° sweptback wing and tail. The lift, drag, and pitching-moment coefficients for two stabilizer settings were obtained at various angles of attack through a Mach number range from 0.50 to 1.23.

NACA RM L8C12

AN INVESTIGATION OF THE DOWNWASH BEHIND A HIGH-ASPECT-RATIO WING WITH VARIOUS AMOUNTS OF SWEEP IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Richard T. Whitcomb. May 11, 1948. 25p. diagrs., 2 tabs. (NACA RM L8C12)

Downwash angles have been measured at vertical positions at the probable tail location behind a high-aspect-ratio wing with an NACA 65-210 section with no sweep and 30° and 45° of sweepback and sweepforward in conjunction with a fuselage at Mach numbers up to 0.96. Presented are the variations of downwash angles with normal-force coefficient and Mach number.

NACA RM L8C15

LANGLEY FULL-SCALE-TUNNEL INVESTIGATION OF THE CHARACTERISTICS IN YAW OF A TRAPEZOIDAL WING OF ASPECT RATIO 4 WITH CIRCULAR-ARC AIRFOIL SECTIONS. Ralph W. May, Jr. and George L. Stevens. August 30, 1948. 19p. diagrs., photos. (NACA RM L8C15)

Results are given of an investigation at an approximate Reynolds number of 4,100,000 and Mach number

of 0.07 to determine the characteristics in yaw of a trapezoidal wing of aspect ratio 4 with circular-arc airfoil sections and 0.20-chord rear and drooped-nose flaps. Measurements of the lift, the lateral force, the rolling moment, and the yawing moment of five configurations were made through a range of angle of attack at several yaw angles ranging from approximately -6° to 18°.

NACA RM L8D06

EFFECT OF HIGH-LIFT DEVICES ON THE LONGITUDINAL AND LATERAL CHARACTERISTICS OF A 45° SWEPTBACK WING WITH SYMMETRICAL CIRCULAR-ARC SECTIONS. Eugene R. Guryansky and Stanley Lipson. October 1, 1948. 45p. diagrs., photo. (NACA RM L8D06)

An investigation was made in the Langley full-scale tunnel at a Reynolds number of 4.5×10^6 of the longitudinal characteristics of several leading-edge and trailing-edge flap configurations and the lateral characteristics of one flapped configuration of a 45° sweptback wing having symmetrical circular-arc sections, aspect ratio 3.5, and taper ratio 0.5. Investigation included tests of chordwise fences with and without a rounded leading-edge modification installed on the outer semispan of the wing.

NACA RM L8D14

PRELIMINARY CORRELATION OF THE EFFECT OF COMPRESSIBILITY ON THE LOCATION OF THE SECTION AERODYNAMIC CENTER AT SUBCRITICAL SPEEDS. Edward C. Polhamus. November 3, 1948. 7p. diagr., tab. (NACA RM L8D14)

A correlation of available two-dimensional airfoil data to determine the effects of compressibility on the location of the section aerodynamic center at low lift coefficients has been made. The results indicate that large forward or rearward movements of the aerodynamic center with Mach number are possible. It appears that thickness ratio is an important parameter controlling the variation with Mach number.

NACA RM L8D30

EFFECT OF LEADING-EDGE HIGH-LIFT DEVICES AND SPLIT FLAPS ON THE MAXIMUM-LIFT AND LATERAL CHARACTERISTICS OF A RECTANGULAR WING OF ASPECT RATIO 3.4 WITH CIRCULAR-ARC AIRFOIL SECTIONS AT REYNOLDS NUMBERS FROM 2.9×10^6 TO 8.4×10^6. Roy H. Lange and Ralph W. May, Jr. November 10, 1948. 70p. diagrs., photos. (NACA RM L8D30)

Results are presented of an investigation at high Reynolds numbers and low Mach numbers in the Langley full-scale tunnel to determine the effects of leading-edge high-lift devices and split flaps on the maximum-lift and lateral characteristics of a rectangular wing of aspect ratio 3.4 with circular-arc airfoil sections. Measurements were made of the static-aerodynamic characteristics in pitch and in yaw of the basic wing and of the wing with several leading-edge high-lift devices and 0.20-chord split flaps deflected alone and in combination with one another. Scale effects were investigated at Reynolds numbers ranging from 2.9×10^6 to 8.4×10^6.

NACA RM L8F16

LOW-SPEED PRESSURE DISTRIBUTIONS OVER THE DROOPED-NOSE FLAP OF A 42° SWEPTBACK WING WITH CIRCULAR-ARC AIRFOIL SECTIONS AT A REYNOLDS NUMBER OF 5.3×10^6. Stanley H. Spooner and Robert L. Woods. September 23, 1948. 28p. diagrs., tab. (NACA RM L8F16)

Pressure distributions over the drooped-nose flap of a 42° sweptback wing having circular-arc airfoil sections are presented for several angles of attack. The drooped-nose-flap normal-force and hinge-moment coefficients are determined. The effects of nose-flap deflection and span and of half-span trailing-edge split flaps are shown. The Reynolds number and Mach number of the investigation were 5.3×10^6 and 0.11, respectively.

NACA RM L8F17

INVESTIGATION OF FLOW CONDITIONS AND THE NATURE OF THE WALL-CONSTRICTION EFFECT NEAR AND AT CHOKING BY MEANS OF THE HYDRAULIC ANALOGY. Clarence W. Matthews and Ray H. Wright. September 1, 1948. 62p. diagrs. (NACA RM L8F17)

Field surveys are presented of subcritical, supercritical, and choking flow about several airfoils at zero lift in a water channel. A qualitative study is made of the effects of the channel walls on supercritical flow about the airfoils, of the development of the choking condition from supercritical flow, and of the effects of airfoil characteristics on the choking stream Mach number. The experimental wall-interference results are compared with results obtained by theoretical calculations.

NACA RM L8F29

AN INVESTIGATION AT LOW SPEED OF A 51.3° SWEPTBACK SEMISPAN WING WITH A RAKED TIP AND WITH 16.7-PERCENT-CHORD AILERONS HAVING THREE SPANS AND THREE TRAILING-EDGE ANGLES. Jack Fischel and Leslie E. Schneiter. July 21, 1948. 52p. diagrs. photos., 2 tabs. (NACA RM L8F29)

Contains results and discussion of aerodynamic and lateral-control investigation at low speed of a 51.3° sweptback semispan wing with a raked tip and with 16.7-percent-chord sealed plain ailerons having spans of 34, 66, and 93 percent of the span of a full-span aileron, each with trailing-edge angles of 6°, 14°, and 25°. Lift and lateral-control data were obtained throughout a large angle-of-attack range. Spanwise variations of rolling-moment and hinge-moment parameters, as well as the effects of the aileron trailing-edge angles, were determined from the aileron configurations tested.

NACA RM L8G05

FULL-SCALE INVESTIGATION OF AN EQUILATERAL TRIANGULAR WING HAVING 10-PERCENT-THICK BICONVEX AIRFOIL SECTIONS. Edward F. Whittle, Jr. and J. Calvin Lovell. September 30, 1948. 32p. diagrs., photos. (NACA RM L8G05)

Contains the results of an investigation made at a Reynolds number of 6.0×10^6 to determine the low-speed characteristics of a wing having triangular plan form, 60° of sweepback at the leading edge, and 10-percent-thick biconvex airfoil sections. The investigation consisted of the determination of the effects on the stalling and static longitudinal characteristics of semispan and full-span leading-edge and trailing-edge flaps and the effects on the static lateral stability characteristics of a vertical fin.

NACA RM L8G22

DOWNWASH, SIDEWASH, AND WAKE SURVEYS BEHIND A 42° SWEPTBACK WING AT A REYNOLDS NUMBER OF 6.8×10^6 WITH AND WITHOUT A SIMULATED GROUND. G. Chester Furlong and Thomas V. Bollech. December 13, 1948. 77p. diagrs., photos., tab. (NACA RM L8G22)

An investigation, with and without a simulated ground, has been conducted to provide flow inclination and wake data behind a 42° sweptback wing. Tests were made for two model configurations; namely, the plain wing and the wing with inboard trailing-edge split flaps and outboard leading-edge flaps deflected. Contour charts of downwash, sidewash, and dynamic-pressure ratio at two longitudinal stations behind the wing (2.0 and 2.8 mean aerodynamic chords) are presented. Integrations have been made to obtain variations of average downwash and dynamic-pressure ratio with angle of attack. The possibility of extending the lifting-line method r) used for calculating the downwash behind unswept wings to the case of a sweptback wing has been briefly investigated.

NACA RM L8H20

AN INVESTIGATION AT LOW SPEED OF A 51.3° SWEPTBACK SEMISPAN WING EQUIPPED WITH 16.7-PERCENT-CHORD PLAIN FLAPS AND AILERONS HAVING VARIOUS SPANS AND THREE TRAILING-EDGE ANGLES. Jack Fischel and Leslie E. Schneiter. November 12, 1948. 81p. diagrs., photo., 2 tabs. (NACA RM L8H20)

Contains results and discussion of an aerodynamic investigation at low speed of a 51.3° sweptback semispan wing equipped with 16.7-percent-chord plain flaps and ailerons having various spans, spanwise locations, and trailing-edge angles. Variation of the lift and lateral-control data with flap or aileron span and spanwise location were determined through a large angle-of-attack range. The effects of aileron trailing-edge angle and the aerodynamic characteristics of a spoiler-aileron configuration on the wing were also determined.

NACA RM L8I03

THE EFFECTS OF HIGH-LIFT DEVICES ON THE LOW-SPEED STABILITY CHARACTERISTICS OF A TAPERED 37.5° SWEPTBACK WING OF ASPECT RATIO 3 IN STRAIGHT AND ROLLING FLOW. M. J. Queijo and Jacob H. Lichtenstein. November 9, 1948. 27p. diagrs., photo., tab. (NACA RM L8I03)

Contains results of tunnel tests to determine effects of various combinations of split flaps, slats, and nose slats on the stability characteristics of a tapered 37.5° sweptback wing of aspect ratio 3 in straight and rolling flow.

NACA RM L8I30

TRANSONIC-FLUTTER INVESTIGATION OF WINGS ATTACHED TO TWO LOW-ACCELERATION ROCKET-PROPELLED VEHICLES. Reginald R. Lundstrom, William T. Lauten, Jr. and Ellwyn E. Angle. November 23, 1948. 24p. diagrs., photos., 3 tabs. (NACA RM L8I30)

Two low-acceleration transonic-flutter vehicles were launched and flown. The first carried two test wings, one of which fluttered at $M = 0.92$ at a frequency of 61.4 cycles per second. The reference flutter speed determined from two-dimensional theory for an unswept wing in incompressible flow is conservative when compared to the experimental flutter speed. The second vehicle carried two test wings, one of which failed at $M = 0.71$ because of a low-frequency divergent oscillation. Since this failure was not caused by conventional flexure-tors on flutter, no comparison with a reference flutter speed can be made.

NACA RM L8J11

INITIAL EXPERIMENTS ON FLUTTER OF UNSWEPT CANTILEVER WINGS AT MACH NUMBER 1.3. W. J. Tuovila, John E. Baker and Arthur A. Regier. January 6, 1949. 23p. diagrs., photos., 2 tabs. (NACA RM L8J11)

This paper contains experimental data for the bending torsion flutter of unswept cantilever wings at Mach number 1.3. Comparison with the theory of flutter at supersonic speeds indicates that the theory is applicable in predicting cantilever-wing flutter. These preliminary experiments consider also various overall effects of center-of-gravity location, elastic-axis location, mass-density parameter, section shape, and some wing-tip moments of inertia.

NACA RM L8K12

LATERAL-CONTROL INVESTIGATION ON A 37° SWEPTBACK WING OF ASPECT RATIO 6 AT A REYNOLDS NUMBER OF 6,800,000. Robert R. Graham and William Koven. January 27, 1949. 58p. diagrs., photo. (NACA RM L8K12)

Lateral-control devices including an aileron, a plain spoiler at two chordwise locations, and a step

spoiler were investigated. The effects of stall control and high-lift devices including a leading-edge flap, slat, and drooped leading edge and split and double slotted trailing-edge flaps on the lateral control characteristics were also investigated. Force and moment data are presented for all the devices and in addition hinge-moment and balance compartment pressure coefficients are presented for the aileron.

NACA RM L8L01

ANALYTICAL CONSIDERATIONS REGARDING A CONTROL-SURFACE BALANCE ARRANGEMENT FOR SUBSONIC AND SUPERSONIC FLIGHT. Thomas A. Toll and Glenn H. Adair. January 10, 1949. 20p. diagrs. (NACA RM L8L01)

Presents results of a simplified analysis to indicate the possibility of utilizing the principle of the sealed internal balance to reduce control-surface hinge moments at both subsonic and supersonic speeds. Certain design considerations and possible advantages of such a balance are discussed.

NACA RM L8L29

LOW-SPEED STATIC-STABILITY AND ROLLING CHARACTERISTICS OF LOW-ASPECT-RATIO WINGS OF TRIANGULAR AND MODIFIED TRIANGULAR PLAN FORMS. Byron M. Jaquet and Jack D. Brewer. March 29, 1949. 44p. diagrs., photos., tab. (NACA RM L8L29)

Presents results of an investigation conducted in the Langley stability tunnel to determine effects of changes in profile and aspect ratio on the low-speed static-stability and rolling characteristics of triangular wings. The investigation was extended to determine the effects of adding fins to the upper surface and of cutting portions from the tips of a triangular wing to form low-aspect-ratio tapered wings. Results are compared with available swept-wing theory and triangular-wing theory.

NACA RM L9B25a

COMPARISON OF SEMISPAN DATA OBTAINED IN THE LANGLEY TWO-DIMENSIONAL LOW-TURBULENCE PRESSURE TUNNEL AND FULL-SPAN DATA OBTAINED IN THE LANGLEY 19-FOOT PRESSURE TUNNEL FOR A WING WITH 40° SWEEPBACK OF THE 0.27-CHORD LINE. Jones F. Cahill. April 22, 1949. 33p. diagrs., photo. (NACA RM L9B25a)

Results obtained in this investigation show that data obtained from semispan-wing tests in the Langley two-dimensional low-turbulence pressure tunnel may be expected to be in good agreement with data obtained from full-span tests of the wing alone except for unusually sensitive configurations where the lift distribution is such that small disturbances may cause a radical change in the location of the original stall or in the manner in which the stall progresses.

NACA RM L9B25b

CONTINUATION OF WING FLUTTER INVESTIGATION IN THE TRANSONIC RANGE AND PRESENTATION OF A LIMITED SUMMARY OF FLUTTER DATA. William T. Lauten, Jr. and J. G. Barmby. April 21, 1949. 21p. diagrs., photos., 2 tabs. (NACA RM L9B25b)

Results of four unswept flutter airfoils attached to two freely falling bodies are reported. One airfoil fluttered at a transonic Mach number of 1.17. Flutter frequency and phasing were recorded. A limited summary of experimental subsonic and supersonic flutter data is included and a critical flutter region is defined.

NACA RM L9E18

EFFECTS OF VARIOUS OUTBOARD AND CENTRAL FINS ON LOW-SPEED STATIC-STABILITY AND ROLLING CHARACTERISTICS OF A TRIANGULAR-WING MODEL. Byron M. Jaquet and Jack D. Brewer. June 29, 1949. 60p. diagrs., photos., 2 tabs. (NACA RM L9E18)

Results of an investigation conducted in Langley stability tunnel to determine effects of various outboard and central-fin arrangements on low-speed static-stability and rolling characteristics of a triangular-wing model are presented. One of the purposes was the determination of the fin configuration to provide good directional stability throughout the lift-coefficient range.

NACA RM L9F24

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF SWEEPBACK ON THE FLUTTER OF A UNIFORM CANTILEVER WING WITH A VARIABLE LOCATED CONCENTRATED MASS. Herbert C. Nelson and John E. Tomassoni. August 31, 1949. 33p. diagrs., tab. (NACA RM L9F24)

An experimental investigation of the effect of sweepback on the flutter characteristics of an untapered cantilever wing carrying a concentrated weight is reported. The investigation covered sweepback angles of 0°, 45°, and 60°. The weight used in the investigation was approximately 14 percent heavier than the wing. The data presented may be used in conjunction with analytical methods of predicting flutter to indicate the validity of the methods used.

NACA RM L9H17

LOW-SPEED STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A CANARD MODEL HAVING A 60° TRIANGULAR WING AND HORIZONTAL TAIL. William R. Bates. November 9, 1949. 16p. diagrs., tab. (NACA RM L9H17)

Contains results of force tests and flow surveys made in the Langley free-flight tunnel to determine the stability and control characteristics of a canard model having a 60° triangular plan-form wing and horizontal tail. Tests were made with the horizontal tail used as a fixed-nose elevator or floating freely at various tab deflections.

NACA RM L9H18

LATERAL-CONTROL INVESTIGATION AT A REYNOLDS NUMBER OF 5,300,000 OF A WING OF ASPECT RATIO 5.8 SWEPTFORWARD 32° AT THE LEADING EDGE. Robert R. Graham. February 7, 1950. 44p. diagrs., photo. (NACA RM L9H18)

Lateral-control devices, including an aileron and plain and step spoilers, were investigated. The effects of an inboard leading-edge flap and a trailing-edge double-slotted flap on the lateral-control characteristics were also investigated. Force and moment data are presented for all the devices and, in addition, hinge-moment, normal-force, and balance-compartment-pressure coefficients are presented for the aileron.

NACA RM L9J07

LOW-SPEED PRESSURE-DISTRIBUTION AND FLOW INVESTIGATION FOR A LARGE PITCH AND YAW RANGE OF THREE LOW-ASPECT-RATIO POINTED WINGS HAVING LEADING EDGE SWEPT BACK 60° AND BICONVEX SECTIONS. Ralph W. May, Jr. and John G. Hawes. November 18, 1949. 109p. diagrs., photos., tab. (NACA RM L9J07)

Low-speed pressure distributions and flow characteristics through a yaw range of 0° to 35° and an angle-of-attack range through the stall are presented for three small-scale low-aspect ratio pointed wings having 10-percent-thick biconvex sections, 60° sweptback leading edge, and 0°, 30°, and -30° trailing-edge sweep. Also given are section lift coefficients and centers of pressure at zero yaw, and wing spanwise load distributions, force, and moment coefficients throughout the yaw range. A correlation is established between the pressure distributions and the vortex flow characteristics.

NACA RM L9J21a

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF ROOT RESTRAINT ON THE FLUTTER OF A SWEPTBACK, UNIFORM, CANTILEVER WING WITH A VARIABLE LOCATED CONCENTRATED MASS. John E. Tomassoni and Herbert C. Nelson. March 31, 1950. 36p. diagrs., tab. (NACA RM L9J21a)

An experimental subsonic flutter investigation of the effect of root restraint on sweptback, uniform, cantilever wings carrying a concentrated weight is reported. The results pertain only to wings with relatively large length-to-chord ratios where the restrained root is a small portion of the whole wing.

NACA RM L9K04

LOW-SPEED INVESTIGATION OF THE AERODYNAMIC LOADS ON THE DROOP-NOSE FLAP OF A WING WITH LEADING EDGE SWEPT BACK 47.5° AND HAVING SYMMETRICAL CIRCULAR-ARC AIRFOIL SECTIONS AT A REYNOLDS NUMBER OF 4.3×10^6. Edward F. Whittle, Jr. and Marvin P. Fink. January 16, 1950. 34p. diagrs., 3 tabs. (NACA RM L9K04)

The results of an investigation of the pressure distribution over the full-span droop-nose flap of a wing with the leading edge swept back 47.5° and having symmetrical circular-arc airfoil sections are presented in this paper. The configurations tested included the basic configuration, the full-span droop-nose flap deflected 10°, 20°, 30°, and 40°, the semi-span plain flap deflected 40°, and both flaps deflected 40°. The investigation was conducted in the Langley full-scale tunnel at a Reynolds number of 4.3×10^6 and a Mach number of 0.07.

NACA RM L9K28a

PRELIMINARY EXPERIMENTS ON FORCES AND MOMENTS OF AN OSCILLATING WING AT HIGH-SUBSONIC SPEEDS. S. A. Clevenson and E. Widmayer, Jr. February 20, 1950. 28p. diagrs., tab. (NACA RM L9K28a)

Experimental results of lifts and moments about the quarter chord of an oscillating wing at high-subsonic Mach numbers are presented. A comparison of the experimental magnitude of the lift vector with the theory as given by Dietze showed good agreement. Comparisons of the moments and the quadrature component of lift with theory indicated that some refinements in the testing technique are necessary for the experimental determination of these quantities in the transonic range.

NACA RM L9L09a

THE EFFECT OF AILERON SPAN AND SPANWISE LOCATION ON THE LOW-SPEED LATERAL CONTROL CHARACTERISTICS OF AN UNTAPERED WING OF ASPECT RATIO 2.09 AND 45° SWEEPBACK. Rodger L. Naeseth and William M. O'Hare. February 10, 1950. 20p. diagrs. (NACA RM L9L09a)

Presents results of a low-speed wind-tunnel investigation of the effects of span and spanwise location of 0.25-chord flap-type ailerons on the lateral control characteristics of an untapered complete wing of aspect ratio 2.09 and 45° sweepback. The tests were made at a Reynolds number of 3,100,000.

NACA RM L9L13

ANALYSIS OF V-g DATA OBTAINED FROM SEVERAL NAVAL AIRPLANES. James O. Thornton. July 7, 1950. 28p. diagrs., 4 tabs. (NACA RM L9L13)

V-g records obtained with the F8F-1, SB2C-5, and F6F-5 airplanes from 1945 to 1949 are analyzed statistically to give the frequency of maximum loads and airspeeds made in bombing, gunnery, dive pull-outs, and simulated attacks. Composite V-g diagrams are shown for the F4U-4 and TBM-3 airplanes.

CURRENT NACA REPORTS

NACA TN 3050

A PHOTOGRAPHIC METHOD FOR DETERMINING VERTICAL VELOCITIES OF AIRCRAFT IMMEDIATELY PRIOR TO LANDING. Emanuel Rind. January 1954. 23p. diagrs., photos. (NACA TN 3050)

A photographic method which has been successfully used for obtaining statistical data on vertical velocities of land-based aircraft immediately prior to landing contact is described. A long-focal-length (40-inch) lens is used. No instrument installation on the aircraft or interference with airport operation is required. A relatively simple data reduction is employed.

NACA TN 3059

ELASTIC BUCKLING UNDER COMBINED STRESSES OF FLAT PLATES WITH INTEGRAL WAFFLE-LIKE STIFFENING. Norris F. Dow, L. Ross Levin and John L. Troutman. January 1954. 19p. diagrs., photos., tab. (NACA TN 3059)

Theory and experiment were compared and found in good agreement for the elastic buckling under combined stresses of long flat plates with integral waffle-like stiffening in a variety of configurations. For such flat plates, 45° waffle stiffening was found to be the most effective of the configurations for the proportions considered over the widest range of combinations of compression and shear.

NACA TN 3064

DATA ON THE COMPRESSIVE STRENGTH OF SKIN-STRINGER PANELS OF VARIOUS MATERIALS. Norris F. Dow, William A. Hickman and B. Walter Rosen. January 1954. 49p. diagrs., photo., 7 tabs. (NACA TN 3064)

Flat skin-stringer compression panels of stainless steel, mild steel, titanium, copper, four aluminum alloys, and a magnesium alloy were tested. The results show the effect of variations in yield stress, Young's modulus, and both yield stress and Young's modulus for constant yield strain on the buckling, and load-shortening characteristics of the panels.

NACA TN 3113

ANALYSIS OF STRAIGHT MULTICELL WINGS ON CAL-TECH ANALOG COMPUTER. Stanley U. Benscoter and Richard H. MacNeal, California Institute of Technology. January 1954. 79p. diagrs., 4 tabs. (NACA TN 3113)

Using the Cal-Tech analog computer, structural analyses have been made for four straight multicell wings. Wings with aspect ratios of 2 and 4 with rectangular and biconvex cross sections have been considered. The wings are supported rigidly along two lines at the faces of the fuselage. Concentrated loads are applied at the intersection points of the ribs and spars. The effects of shearing strains in the ribs and spars are included. Deflections and all internal force quantities have been recorded as well as vibration modes and frequencies.

NACA TN 3116

CORRELATIONS INVOLVING PRESSURE FLUCTUATIONS IN HOMOGENEOUS TURBULENCE. Mahinder S. Uberoi, Johns Hopkins University. January 1954. 61p. diagrs., 2 tabs. (NACA TN 3116)

It is shown that the correlation of fluctuating static pressure (in an incompressible and homogeneous turbulence) with any fluctuating quantity in the flow field can be expressed in terms of the correlation of the same quantity with two or more components of the velocity. The correlations of pressure with itself and of pressure with two velocity components are investigated in detail for the case of isotropic turbulence. A postulated relation between the fourth-order and second-order correlations is investigated. The consequences of this relation are compared with the measurements of the fourth-order correlations. The root-mean-square pressure and pressure gradients are computed from second-order correlation for a range of turbulence Reynolds numbers. Since the pressure gradient is related to diffusion of marked particles from a source, the computed pressure-gradient level is compared with that calculated from a set of diffusion measurements. The triple correlation equation and plausible hypotheses relating higher order correlations with second-order correlation are examined for the possibility of getting a determinate set of equations for isotropic turbulence.

NACA TN 3118

DESIGN DATA FOR MULTIPOST-STIFFENED WINGS IN BENDING. Roger A. Anderson, Aldie E. Johnson, Jr. and Thomas W. Wilder, III. January 1954. 31p. diagrs., 3 tabs. (NACA TN 3118)

The results of a computational program are presented which give numerical values of the stiffnesses required of the various components of a multipost-stiffened wing to achieve desired buckling-stress values under bending loads. Two arrangements of the posts are considered, upright posts and posts used as diagonals of a Warren truss. This work extends and summarizes the calculations presented in NACA RM L52K10a.

NACA TN 3119

STATIC PROPERTIES AND RESISTANCE CHARACTERISTICS OF A FAMILY OF SEAPLANE HULLS HAVING VARYING LENGTH-BEAM RATIO. Arthur W. Carter and David R. Woodward. January 1954. 38p. diagrs., photo., 3 tabs. (NACA TN 3119)

The principal results of the investigation of the static properties of a family of seaplane hulls are presented in charts from which draft, trim, and upsetting moment may be obtained for wide ranges of load, center-of-gravity location, and angle of roll. Charts are presented for the determination of resistance and trimming moment for length-beam ratios of 6 and 15.

NACA TN 3120

SPAN LOAD DISTRIBUTIONS RESULTING FROM CONSTANT VERTICAL ACCELERATION FOR THIN SWEPTBACK TAPERED WINGS WITH STREAMWISE TIPS. SUPERSONIC LEADING AND TRAILING EDGES. Isabella J. Cole and Kenneth Margolis. January 1954. 62p. diagrs., 2 tabs. (NACA TN 3120)

On the basis of the linearized supersonic-flow theory, equations for the span load distribution resulting from constant vertical acceleration (i.e., linear angle-of-attack variation with time) are derived for a series of thin sweptback tapered wings with streamwise tips. The analysis is valid, in general, at Mach numbers for which the wing leading and trailing edges are supersonic. Computational results are presented in the form of generalized design curves which permit fairly rapid estimation of the load distribution for broad ranges of the parameters aspect ratio, taper ratio, leading-edge sweepback, and Mach number.

NACA TN 3121

SOME EFFECTS OF ASPECT RATIO AND TAIL LENGTH ON THE CONTRIBUTION OF A VERTICAL TAIL TO UNSTEADY LATERAL DAMPING AND DIRECTIONAL STABILITY OF A MODEL OSCILLATING CONTINUOUSLY IN YAW. Lewis R. Fisher. January 1954. 49p. diagrs., photos., 6 tabs. (NACA TN 3121)

A fuselage—vertical-tail combination with tails of two aspect ratios, each of which was tested at four fuselage tail lengths, was oscillated in yaw through a range of reduced-frequency parameter corresponding to the lateral motions of airplanes. The phase lag of the tail force was measured during oscillation and converted to damping in yaw to determine the effects of varying these parameters. A complementary theoretical analysis based on the finite-span theory of Biot and Boehnlein is made on the effects of tail length and aspect ratio on the unsteady lateral damping and directional stability.

NACA TN 3122

EXPERIMENTAL INVESTIGATION AT A MACH NUMBER OF 2.41 OF AVERAGE SKIN-FRICTION COEFFICIENTS AND VELOCITY PROFILES FOR LAMINAR AND TURBULENT BOUNDARY LAYERS AND AN ASSESSMENT OF PROBE EFFECTS. Robert M. O'Donnell. January 1954. 38p. diagrs., photos. (NACA TN 3122)

Average skin-friction coefficients for laminar and turbulent flows were measured on a hollow cylinder at a Mach number of 2.41 and over a Reynolds number range from 0.06×10^6 to 0.95×10^6 per inch. Comparisons with various laminar- and turbulent-boundary-layer theories are presented, together with an assessment of probe effects.

NACA TN 3124

A METHOD FOR ESTIMATING THE EFFECT OF TURBULENT VELOCITY FLUCTUATIONS IN THE BOUNDARY LAYER ON DIFFUSER TOTAL-PRESSURE-LOSS MEASUREMENTS. Jerome Persh and Bruce M. Bailey. January 1954. 16p. diagrs. (NACA TN 3124)

A method has been devised for estimating the effect of turbulent velocity fluctuations on diffuser total-pressure-loss measurements. In the development of this method, continuity of flow is stipulated, and it is assumed that the inlet conditions and the diffuser dimensions are accurately known, that the flow is symmetrical, and that the velocity outside the boundary layer at the downstream measuring stations is not measurably influenced by turbulent velocity fluctuations. Only the case of a conical diffuser with incompressible flow is considered, although the procedure may be easily modified to include compressible-flow considerations.

NACA TN 3131

ON THE KERNEL FUNCTION OF THE INTEGRAL EQUATION RELATING THE LIFT AND DOWNWASH DISTRIBUTIONS OF OSCILLATING FINITE WINGS IN SUBSONIC FLOW. Charles E. Watkins, Harry L. Runyan and Donald S. Woolston. January 1954. 44p. (NACA TN 3131)

The kernel function of an integral equation relating the downwash to the lift distribution of a finite wing oscillating in subsonic compressible flow is treated. The kernel is reduced to a form which is amenable to calculations and the types of singularities are shown. As a check, it is shown that the kernel for the three-dimensional case reduces exactly to the known kernel for the two-dimensional case. In addition, results for the special cases of Mach number of 0 (incompressible case) and frequency of 0 (steady case) are given.

NACA TN 3132

FATIGUE TESTS AT STRESSES PRODUCING FAILURE IN 2 TO 10,000 CYCLES. 24S-T3 AND 75S-T6 ALUMINUM-ALLOY SHEET SPECIMENS WITH A THEORETICAL STRESS-CONCENTRATION FACTOR OF 4.0 SUBJECTED TO COMPLETELY REVERSED AXIAL LOAD. Herbert F. Hardrath and Walter Illg. January 1954. 14p. diagrs., photo., 2 tabs. (NACA TN 3132)

Notched specimens made of 24S-T3 and 75S-T6 aluminum-alloy sheet material, with theoretical stress-concentration factors equal to 4.0, were subjected to completely reversed axial loads. Failures occurred in less than 50 cycles at two-thirds of the static tensile strength and in as few as 2 cycles when the applied load was near the static strength of the specimen. The S-N curves were found to be concave upward for almost the complete range of fatigue lives; a reversal of curvature occurred at about 10

cycles of load. The fatigue strengths were equivalent for specimens made of each of the two materials and tested at stresses below 25 ksi; above that stress the 75S-T6 specimens had the greater fatigue strength. Compared on the basis of percent of ultimate tensile strength, the 24S-T3 specimens were stronger at all stress levels. Test techniques and special test apparatus are described.

NACA TN 3133

THE FREE-STREAM BOUNDARIES OF TURBULENT FLOWS. Stanley Corrsin and Alan L. Kistler, Johns Hopkins University. January 1954. 109p. diagrs., photos. (NACA TN 3133)

An experimental and theoretical study has been made of the instantaneously sharp and irregular front which separates turbulent fluid from contiguous "nonturbulent" fluid at a free-stream boundary. The overall behavior of the front is described statistically in terms of its wrinkle-amplitude growth and its lateral propagation relative to the fluid as functions of downstream coordinate. It is proposed and justified that the front actually consists of a very thin fluid layer in which direct viscous forces transmit mean and fluctuating vorticity to previously nonturbulent fluid. Outside this "laminar superlayer" there is presumably a field of irrotational velocity fluctuations (the "nonturbulent" flow) with constant mean velocity. Theoretical analysis based on this physical picture gives results which are in plausible agreement with experimental results for three turbulent shear flows.

NACA TN 3136

CREEP BENDING AND BUCKLING OF LINEARLY VISCOELASTIC COLUMNS. Joseph Kempner, Polytechnic Institute of Brooklyn. January 1954. 22p. diagrs. (NACA TN 3136)

The general dynamic equation of creep bending of a beam loaded laterally and axially was derived for a linearly viscoelastic material whose mechanical properties can be characterized by four parameters. The material can exhibit instantaneous and retarded elasticity as well as pure flow. The equation was used to determine creep characteristics of a beam in pure bending and a column with an initially sinusoidally deformed axis. The results showed that creep deflection characteristics of the beam are identical to the creep strain characteristics of a bar under simple tension or compression. For compressive end loads less than the Euler load, the column exhibited creep deflections which increase continuously with time and approach infinity only as time approaches infinity.

NACA TN 3137

CREEP BENDING AND BUCKLING OF NONLINEARLY VISCOELASTIC COLUMNS. Joseph Kempner, Polytechnic Institute of Brooklyn. January 1954. 27p. diagrs., 3 tabs. (NACA TN 3137)

Differential equations of bending of an idealized H-section beam column were derived for a nonlinearly viscoelastic material whose mechanical properties are analogous to a model consisting of a linear spring in series with a nonlinear dashpot whose strain rate is proportional to a power of the applied stress. The equations were used to obtain the creep-bending deflections of a beam in pure bending and of a column with initial sinusoidal deviation from straightness. The results for the simple beam showed that the deflections vary linearly with time. The results for the column, with the assumption that the original shape was maintained, showed the existence of a finite critical time at which the deflections become indefinitely large. The critical time decreases rapidly with increasing axial compression and column inaccuracy.

NACA TN 3138

CREEP BUCKLING OF COLUMNS. Joseph Kempner and Sharad A. Patel, Polytechnic Institute of Brooklyn. January 1954. 24p. diagrs., 2 tabs. (NACA TN 3138)

Formulas are presented for the determination of the creep deflection-time characteristics of an initially curved idealized H-section column. These results were obtained from closed-form solutions of the differential equation of bending (derived in NACA TN 3137) of a beam column whose creep properties are of a nonlinearly viscoelastic nature. The critical time (the time required for infinite deflections to develop) established by these solutions is tabulated and plotted for a wide range of the parameters involved.

NACA TN 3139

TIME-DEPENDENT BUCKLING OF A UNIFORMLY HEATED COLUMN. Nathan Ness, Polytechnic Institute of Brooklyn. January 1954. 18p. diagrs. (NACA TN 3139)

A theoretical investigation is presented of the time-temperature- dependent buckling of a pin-jointed constant-section column, whose initial curvature is defined by a half-sine wave when the material is linearly viscoelastic and is heated uniformly along the column at a prescribed time rate. It was found that the deviations from straightness increase with time and become indefinitely large when heating reduces the Young's modulus of the material to the value at which the applied load is the Euler load of the column. When the column is heated very rapidly this critical time represents its limit of usefulness. When heating takes place less rapidly the deflections cause bending stresses exceeding the yield stress of the material at a time considerably smaller than the critical time.

NACA TN 3157

METHOD FOR CALCULATION OF COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH AXIAL PRESSURE GRADIENT AND HEAT TRANSFER. Paul A. Libby and Morris Morduchow, Polytechnic Institute of Brooklyn. January 1954. 44p. diagrs. (NACA TN 3157)

A rapid and sufficiently accurate method, for most practical purposes, of determining laminar-boundary-layer characteristics in flow with a given free-stream Mach number and given velocity distribution at the edge of the boundary layer is presented. The method can be easily applied to flow with zero pressure gradient for any (constant) Prandtl number of the order of unity and any given temperature distribution along the wall. For flow in an axial pressure gradient, the method can be applied for a Prandtl number of unity and any given uniform wall temperature.

NACA RM E53J07

MEASUREMENT OF HEAT-TRANSFER AND FRICTION COEFFICIENTS FOR FLOW OF AIR IN NONCIRCULAR DUCTS AT HIGH SURFACE TEMPERATURES. Warren H. Lowdermilk, Walter F. Weiland, Jr. and John N. B. Livingood. January 1954. 26p. diagrs. (NACA RM E53J07)

Measurements of average heat-transfer and friction coefficients were obtained with air flowing through electrically heated ducts having square, rectangular (aspect ratio, 5), and triangular cross sections for a range of surface temperature from 540° to 1780° R and Reynolds number from 1000 to 330,000. The results indicate that the effect of heat flux on correlations of the average heat-transfer and friction coefficients is similar to that obtained for circular tubes in a previous investigation and was nearly eliminated by evaluating the physical properties and density of the air at a film temperature halfway between the average surface and fluid bulk temperatures. With the Nusselt and Reynolds numbers based on the hydraulic diameter of the ducts, the data for the noncircular ducts could be represented by the same equations obtained in the previous investigation for circular tubes. Correlation of the average difference between the surface corner and midwall temperatures for the square duct was in agreement with predicted values from a previous analysis. However, for the rectangular and triangular ducts, the measured corner temperature was greater by approximately 20 and 35 percent, respectively, than the values predicted by analysis.

NACA TM 1364

THE PLANE PROBLEM OF THE FLAPPING WING. (Das ebene problem des schlagenden flugels). Walter Birnbaum. January 1954. 38p. diagrs., tab. (NACA TM 1364. Trans. from Zeitschrift für augewandte Mathematik und Mechanik, v.4, no.4, August 1924, p.277-292).

A theoretical study, based on vortex theory as applied to the linearized equations of motion, is made of the air forces on wings of infinite aspect ratio in incompressible flow. Expressions for forces and moments associated with steady harmonic oscillations in vertical translation and pitching of wings are derived in the form of power series in terms of a reduced frequency parameter. Use is made of the derived forces first to treat the problem of propulsion due to wing flapping and second to determine theoretical flutter speeds of some simple spring mounted configurations.

Royal Aircraft Establishment (Gt. Brit.)
SOME NOTES ON THE DESIGN AND PERFORMANCE OF A THERMAL WATER CONTENT METER FOR USE IN CLOUDS. J. Rudman and F. J. Bigg. September 1953. 33p. diagrs., photos. (RAE Tech. Note Mech. Eng. 145)

Various methods of measuring the liquid water content of clouds are briefly reviewed and their probable applications pointed out. It is concluded that the best type of indicator for use primarily as a warning instrument in conditions of icing is one of a thermal type. An instrument is described which consists of two small heated cylinders, one exposed and the other in a sheltered position. Free water caught on the exposed cylinder produces a temperature difference, relative to the sheltered one, which is used as a measure of free water content. A theoretical analysis of the performance of this type of instrument shows that it is likely to be satisfactory as a warning device but only good for accurate measurement over a limited range of water concentrations, unless a resetting process is used.

CORROSION, STRESS-CORROSION AND FATIGUE TESTS ON AN ALUMINIUM ALLOY HAVING A HIGH YOUNG'S MODULUS. G. Meikle, C. Braithwaite and M. S. Binning. September 1953. 7p. diagr., 2 tabs. (RAE Tech. Note Met. 180)

Corrosion tests have been made on an aluminum alloy containing 10.5 percent silicon and other elements to produce a high "E" value. The corrosion resistance of the alloy was not good, having lost about 17 percent of the proof stress and about 30 percent of the U. T. S. in 12 months' exposure to sea water spray. The stress corrosion resistance of the alloy was not very good. High fatigue results showed that improvement was imparted to the solution treated material but not to be fully heat-treated alloy by polishing. Reverse bend fatigue tests also showed an improvement by polishing the solution treated alloy but no improvement by polishing the fully heat-treated material.

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECT OF HEATING SOME ALUMINIUM ALLOYS FOR SHORT PERIODS UP TO 340°C. September 1953. 10p. diagrs., 3 tabs. (RAE Tech. Note Met. 181)

Samples of 20 S.W.G. (0.036 in.) sheets of DTD.610, DTD.546, and DTD.687 were heated at 200°, 250°, 300°, and 340° C for periods from 5 seconds to 32 minutes. The loss in strength of DTD.610 and DTD.546 at 200° C is negligible but becomes appreciable as the temperature is increased. DTD.687 loses strength at 200° C even with very short periods of heating. When heated at 340° C, resolution occurs in DTD.687 which, on subsequent natural ageing, offsets the loss of strength due to softening at 340° C.

N-28057*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) THE PERFORMANCE OF A MULTI-ENGINE HELICOPTER FOLLOWING FAILURE OF ONE ENGINE DURING TAKE-OFF OR LANDING. A. L. Oliver. October 30, 1953. 15p. diagrs., tab. (AAEE/Res/277)

A theoretical analysis is made of the performance of multiengine helicopters following failure of one engine in take-off and landing from the type of site proposed for civil operation in built-up areas. The performance of a twin engine helicopter of similar class to the Bristol 173 appears to be just adequate for safe operation from such a site but the nicety of handling judgment involved in return landings may make the performance difficult to achieve. A take-off technique allowing climb-away after engine failure at any stage is preferable but this is not possible for the twin engine machine within the space available. It is possible if the twin engines are replaced by four of the same effective total power but only if a turning climb-away is made after engine failure. A helicopter with sufficient performance for a straight climb-away can in general hover with one engine inoperative.

ACTUATOR DISC APPLIED TO WALL BOUNDARY LAYERS IN CASCADES. W. R. Hawthorne and J. H. Horlock. December 22, 1952. 32p. diagrs. (ARC 15,490; EA 270)

Using the actuator disk theory developed by Bragg and Hawthorne and Pinsley, a solution for the flow of a perfect fluid with initial velocity gradients through a moving cascade is found. The boundary-layer form factor at exit from the cascade is shown to be dependent upon the entry boundary-layer parameters, the exit air angle relative to the cascade, and the ratio of cascade blade speed to the main stream axial velocity at entry. A comparison is made between the values of these variables at which the cascade would stall, and those at which the flow might be expected to break away from the wall. The investigation is extended to consider a complete compressor stage.

Aeronautical Research Council (Gt. Brit.)
ON THE SOLUTION OF THE NAVIER-STOKES EQUATIONS FOR A TYPE OF STEADY RADIALLY-SYMMETRIC VISCOUS FLOW. S. C. R. Dennis. March 11, 1953. 13p. diagrs. (ARC 15,723; FM 1878)

The solution of the Navier-Stokes equations for the steady motion of a viscous fluid near an infinite rotating disk can be made to depend upon the solution of a pair of simultaneous nonlinear ordinary differential equations; the same equations govern the flow between two coaxial rotating disks. In this paper a method of solution is developed sufficiently to give some numerical results in a number of related cases. The results given are not necessarily unique, for in some cases the equations have been found to admit of more than one solution. Further solutions are not considered here, but it is hoped in a later paper to describe a method of obtaining them.

THE REPRESENTATION OF GAS PROPERTIES IN TERMS OF MOLECULAR CLUSTERS. Harold W. Woolley. March 1, 1952. ii, 13p. diagrs., tabs. (National Bureau of Standards. Rept. 1491)

This report presents a new and more adequate method for representing the actual thermodynamic properties of nonpolar gases, through the modification of the usual selection of force law parameters for the Lennard-Jones type of interaction potential. Instructions and generalized tables and charts are included which, together with existing tables of second and third virial coefficients, facilitate the fitting of experimental data for all nonpolar gases. Results are shown for A, N_2, CO, CO_2, CH_4, C_2H_4.

DECLASSIFIED NACA REPORTS

THE RECLASSIFICATION CHANGES LISTED IN THIS ISSUE COMPLETE THE ACTION REQUIRED BY EXECUTIVE ORDER NO. 10501 ON REPORTS INITIALLY ISSUED BY THE NACA AS RESTRICTED.

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM RESTRICTED TO UNCLASSIFIED, 12/14/53.

NACA RM 8C29

A RESTRICTED LIST OF AIRCRAFT MATERIALS RESEARCH PROJECTS. Sponsored by Government Agencies. May 4, 1948. 95p. (NACA RM 8C29)

This report contains a selected list of Government sponsored research projects on related aircraft materials in effect during the calendar year 1947. Information is contained on titles, description, sponsoring and conducting agencies.

NACA RM A7D10

THE DEVELOPMENT OF JET-ENGINE NACELLES FOR A HIGH-SPEED BOMBER DESIGN. Robert E. Dannenberg. August 29, 1947. 37p. diagrs., photos., tab. (NACA RM A7D10)

The results of an experimental investigation made for the purpose of developing suitable jet-engine nacelle designs for a high-speed medium bomber are presented. Two types of nacelles were investigated, the first enclosing two 4000-pound-thrust jet engines and a 65-inch-diameter landing wheel and the second enclosing a single 4000-pound-thrust jet engine. Both types of nacelles were tested in positions underslung beneath the wing and centrally located on the wing. The report summarizes the low-speed investigation and includes some results from the high-speed portion.

NACA RM A7I06

AN EXPERIMENTAL INVESTIGATION OF NACA SUBMERGED AIR INLETS ON A 1/5-SCALE MODEL OF A FIGHTER AIRPLANE. Donald E. Gault. December 5, 1947. 32p. diagrs., photos., 4 tabs. (NACA RM A7I06)

The results of an experimental investigation of an NACA submerged inlet system on a 1/5-scale model of a fighter airplane are presented. Duct system total pressure losses and pressure distributions over the lip and ramp were obtained. It is shown that the inlet location investigated is unsatisfactory.

NACA RM A7I26

PRELIMINARY RESULTS OF A FLIGHT INVESTIGATION TO DETERMINE THE EFFECT OF NEGATIVE FLAP DEFLECTION ON HIGH-SPEED LONGITUDINAL-CONTROL CHARACTERISTICS. Maurice D. White, Melvin Sadoff, Lawrence A. Clousing and George E. Cooper. December 16, 1947. 22p. diagrs., photos. (NACA RM A7I26)

Flight tests were conducted on two airplanes having wings of different airfoil section to determine the effect of deflecting the landing flaps upward on the high-speed longitudinal-control characteristics. For the airplane with the NACA 66-series airfoil, a decrease in the diving tendency at high Mach numbers resulted from a reduction in the variation of wing and tail angle of attack with Mach number with deflected flaps. For the airplane with the NACA 230-series airfoil, a change in the pitching moment of the airplane without the tail apparently offset the effect produced by the reduction of the angle-of-attack variation so that no appreciable improvement in diving tendencies resulted with deflected flaps.

NACA RM A7I30

AN EXPERIMENTAL INVESTIGATION OF THE DESIGN VARIABLES FOR NACA SUBMERGED DUCT ENTRANCES. Emmet A. Mossman and Lauros M. Randall. January 8, 1948. 59p. diagrs., 3 tabs. (NACA RM A7I30)

The effect of configuration modifications on the characteristics of NACA submerged duct entrances is presented. These tests were made with the duct inlet installed in the wall of an 8-inch by 36-inch wind channel. The modifications investigated were ramp plan form, ramp angle, width-to-depth ratio, ramp floor shape, deflectors and boundary-layer thickness.

NACA RM A7J13

AN ANALYSIS OF THE EFFECTS OF WING ASPECT RATIO AND TAIL LOCATION ON STATIC LONGITUDINAL STABILITY BELOW THE MACH NUMBER OF LIFT DIVERGENCE. John S. Axelson and J. Conrad Crown. January 9, 1948. 14p. diagrs. (NACA RM A7J13)

An analysis of the influence of wing aspect ratio and tail location on the effects of compressibility on static longitudinal stability indicates that the use of reduced wing aspect ratios or short tail lengths lead to serious reduction in high-speed stability below the Mach number of lift divergence.

NACA RM A7J22

HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A MODEL TAIL PLANE WITH MODIFIED NACA 65-010 SECTIONS AND 0° AND 45° SWEEPBACK. Joseph L. Anderson and Andrew Martin. January 12, 1948. 85p. diagrs., photo., 2 tabs. (NACA RM A7J22)

This report presents high-speed aerodynamic characteristics determined from wind-tunnel tests of a model tail plane having modified NACA 65-010 sections and a tapered plan form. Results are shown for the tail plane in an unswept and a 45° sweptback condition. For the unswept tail the Mach number of lift divergence was 0.80 while for the sweptback tail it was above 0.875. The report shows how the substitution of a 45° sweptback horizontal tail for an unswept tail affects the longitudinal stability and control forces of an airplane.

NACA RM A7J23

HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF FOUR THIN NACA 63-SERIES AIRFOILS. Richard J. Ilk. December 31, 1947. 53p. diagrs., photo., tab. (NACA RM A7J23. Now issued as TN 2670)

This report contains the results of high-speed wind-tunnel tests made of the NACA 63-206, 63-208, 63-210, and 63-212 airfoil sections. The results indicate the effect of thickness on the aerodynamic characteristics of thin NACA 63-series airfoils. The data of these tests have been compared to similar data for corresponding NACA 64-series airfoils to show the effect of thickness distribution on the high-speed aerodynamic characteristics of NACA 6-series airfoils. It was concluded that, although the differences are small, the aerodynamic characteristics of thin NACA 64-series airfoils are more favorable for high-speed applications than those of comparable NACA 63-series airfoils.

NACA RM A7L02

A SUMMARY AND ANALYSIS OF WIND-TUNNEL DATA ON THE LIFT AND HINGE-MOMENT CHARACTERISTICS OF CONTROL SURFACES UP TO A MACH NUMBER OF 0.90. John A. Axelson. April 30, 1948. 43p. diagrs., tab. (NACA RM A7L02)

This report contains an extensive summary of wind-tunnel data showing the lift and hinge-moment characteristics of control surfaces up to a Mach number of 0.90. The many factors affecting C_{h_α}, C_{h_δ}, C_{L_α}, and C_{L_δ} are discussed, including sweep, airfoil section, aerodynamic balance, control surface profile, and trailing-edge angle.

NACA RM A8H12

HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A LATERAL-CONTROL MODEL. I - NACA 0012-64 SECTION WITH 20-PERCENT-CHORD PLAIN AILERON AND 0° AND 45° SWEEPBACK. Joseph L. Anderson and Walter J. Krumm. September 27, 1948. 28p. diagrs., photo., 2 tabs. (NACA RM A8H12)

Wind-tunnel tests were made to determine the aerodynamic and lateral-control characteristics of a semispan wing having the NACA 0012-64 section. The characteristics were determined through a large Mach number range for the wing unswept and swept back 45° and for a 20-percent-chord, plain, trailing-edge aileron. Results indicate an aileron overbalance and effectiveness reversal at high subsonic Mach numbers for the wing unswept but only an overbalance for the wing swept back 45°.

NACA RM A9G19

COMPARISON OF THE AERODYNAMIC CHARACTERISTICS OF THE NACA 0010 AND 0010-64 AIRFOIL SECTIONS AT HIGH SUBSONIC MACH NUMBERS. Perry P. Polentz. October 7, 1949. 23p. diagrs., tab. (NACA RM A9G19)

Section lift, drag, and pitching-moment characteristics of the NACA 0010 and NACA 0010-64 airfoil sections measured at Mach numbers up to 0.91 and Reynolds numbers between 1.0×10^6 and 1.9×10^6 are presented. Comparisons are made to determine the principal effects of varying the chordwise location of the maximum thickness.

NACA RM A9K22

EXPLORATORY INVESTIGATION OF THE EFFECT OF SKEWED PLAIN NOSE FLAPS ON THE LOW-SPEED CHARACTERISTICS OF A LARGE-SCALE TRIANGULAR-WING-FUSELAGE MODEL. Bradford H. Wick and David Graham. January 12, 1950. 12p. diagrs., photo. (NACA RM A9K22)

Presented are lift, drag, and pitching-moment data obtained from tests of a triangular-wing-fuselage combination with skewed nose flaps. The Reynolds numbers of the tests were 12.5 and 14.1 million (based on the wing mean aerodynamic chord). The semi plan form of the flaps was such that the flap chord varied from 0 percent wing chord at the model center line to 100 percent at about 91-percent wing semispan. It was concluded that skewed nose flaps of the investigated plan form are a promising means of delaying both the leading-edge separation and the tip stalling that occur on a thin, low-aspect-ratio triangular wing.

NACA RM A9L27

HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A LATERAL-CONTROL MODEL. II - MODIFIED NACA 0012-64 SECTION WITH A 26.6-PERCENT-CHORD, PLAIN, TRAILING-EDGE AILERON; WING UNSWEPT AND SWEPT BACK 45°. Walter J. Krumm and Joseph L. Anderson. March 15, 1950. 55p. diagrs., photo., 2 tabs. (NACA RM A9L27)

Wind-tunnel tests were made to determine the aerodynamic characteristics of a semispan model wing having a modified NACA 0012-64 section. The lateral-control characteristics for a 26.6-percent-chord, plain, trailing-edge aileron were determined for a Mach number range from 0.40 through 0.925 with the wing unswept and swept back 45°.

NACA RM E6I20

ALTITUDE-WIND-TUNNEL INVESTIGATIONS OF THRUST AUGMENTATION OF A TURBOJET ENGINE. I - PERFORMANCE WITH TAIL-PIPE BURNING. W. A. Fleming and R. O. Dietz. September 25, 1946. 56p. diagrs., photos. (NACA RM E6I20)

Engine thrust and fuel consumption were determined for a wide range of simulated flight conditions and tail-pipe fuel flows. The investigation was particularly directed toward evaluation of thrust augmentation for high-speed and high-altitude flight. The engine tail pipe was modified for the investigation to reduce the gas velocity at the inlet of the tail-pipe combustion chamber. The general trends of the experimental values were in agreement with values calculated from theoretical equations.

NACA RM E6K27

INVESTIGATION OF SHOCK DIFFUSERS AT MACH NUMBER 1.85. I - PROJECTING SINGLE-SHOCK CONES. W. E. Moeckel, J. F. Connors and A. H. Schroeder. June 17, 1947. 47p. diagrs., photos. (NACA RM E6K27)

Single-shock cones having angles of 20°, 30°, 40°, 50°, 60°, and 70° were tested with curved and straight diffuser-inlet sections. The variation of total-pressure recovery with tip projection and outlet area was investigated for each cone to determine optimum contraction ratios and shock locations. The effect of angle of attack was also investigated for several configurations. Maximum total-pressure recovery was obtained with the 50° cone using the straight inlet. The highest total-pressure recoveries were obtained with subsonic entrance flow.

NACA RM E6L13

INVESTIGATION OF SHOCK DIFFUSERS AT MACH NUMBER 1.85. II - PROJECTING DOUBLE-SHOCK CONES. W. E. Moeckel, J. F. Connors and A. H. Schroeder. June 17, 1947. 41p. diagrs., photos. (NACA RM E6L13)

The total-pressure recovery (at a Mach number of 1.85) of a shock diffuser having projecting cones designed to produce two oblique shocks ahead of the diffuser inlet was investigated. Four cones with different included angles were used. Each cone was investigated with a straight and with a curved diffuser-inlet section. The effect of angle of attack and the distribution of static and total pressures at the diffuser outlet were also investigated for the best configurations. The highest total-pressure recoveries were obtained with subsonic inlet flow. The results were compared with those obtained with single-shock cones.

NACA RM E6L27a

CHARACTERISTICS OF A HOT JET DISCHARGED FROM A JET-PROPULSION ENGINE. William A. Fleming. December 27, 1946. 20p. diagrs. (NACA RM E6L27a)

An investigation of a heated jet was conducted to provide information by which an engine could be so located in an airplane that no external surface is overheated by the jet. The temperature and the velocity on the axis of the jet and the diameter of the jet are presented nondimensionally as functions of the axial distance from the jet-nozzle outlet and the diameter of the jet at the vena contracta.

NACA RM E7B11h

COMPUTED TEMPERATURE DISTRIBUTION AND COOLING OF SOLID GAS-TURBINE BLADES. J. George Reuter and Carl Gazley, Jr. February 11, 1947. 13p. diagrs., tab. (NACA RM E7B11h)

Computations were made to determine the effects of gas temperature, blade-root temperature, blade thermal conductivity, and net gas-to-metal heat-transfer coefficient on the temperature distribution in a typical solid turbine blade.

NACA RM E7C12

ALTITUDE-WIND-TUNNEL INVESTIGATION OF THRUST AUGMENTATION OF A TURBOJET ENGINE. II - PERFORMANCE WITH WATER INJECTION AT COMPRESSOR INLET. Robert O. Dietz and William A. Fleming. May 19, 1947. 33p. diagrs. (NACA RM E7C12)

Engine performance at an engine speed of 7600 rpm was obtained over a wide range of water-air ratios at pressure altitudes of 5,000 and 20,000 feet and at a ram-pressure ratio corresponding to a flight Mach number of about 0.265. A fixed-area tail-pipe nozzle 16-3/8 inches in diameter was used for this investigation. Data are presented to show the effect of water injection on engine performance. A discussion of the effect of water injection on the pressure and temperature distribution at the compressor outlet of the turbojet engine is included.

NACA RM E7C26

THE USE OF PERFORATED INLETS FOR EFFICIENT SUPERSONIC DIFFUSION. John C. Evvard and John W. Blakey. June 25, 1947. 34p. diagrs., photo. (NACA RM E7C26. Now issued as RM E51B10)

The use of wall perforations on supersonic diffusers to avoid the internal contraction-ratio limitation is described. Experimental results at a Mach number of 1.85 on a preliminary model of a perforated diffuser having a geometric internal contraction ratio of 1.49 (the isentropic value) are presented. A theoretical discussion of the flow coefficients as well as the size and the spacing of the perforations is also included. At angles of attack of 0°, 3°, and 5°, total-pressure recoveries of 0.931, 0.920, and 0.906, respectively, were obtained.

NACA RM E7D22

A FUEL-DISTRIBUTION CONTROL FOR CONTINUOUS-FLOW MANIFOLD INJECTION ON RECIPROCATING ENGINES. Harold Gold and David M. Straight. June 6, 1947. 16p. diagrs., photos. (NACA RM E7D22)

A fuel-distribution control for continuous-flow manifold injection on reciprocating engines is described. A method of installation of the control on an engine is suggested.

NACA RM E7E12

PRELIMINARY INVESTIGATION OF EFFECTS OF GAMMA RADIATION ON AGE-HARDENING RATE OF AN ALUMINUM-COPPER ALLOY. J. Howard Kittel. June 20, 1947. 4p. diagr. (NACA RM E7E12)

A preliminary investigation was made to determine the effects of gamma radiation on the age-hardening rate of an aluminum-copper alloy at temperatures of 32° and 70° F. The gamma radiation from a 100-milligram radium source appeared to have no significant effect on the age-hardening rate of the alloy. A metallographic examination of the test specimens showed no microstructural changes that could be attributed to the gamma radiation.

NACA RM E7E13

PRELIMINARY INVESTIGATION OF EFFECTS OF ALPHA-PARTICLE BOMBARDMENT ON THE CREEP RATE OF ALUMINUM. J. Howard Kittel. July 3, 1947. 6p. diagrs. (NACA RM E7E13)

A preliminary investigation was made to determine the effects of alpha-particle bombardment on the creep rate of aluminum wire at 400° F. The alpha radiation from an 85-millicurie polonium source appeared to decrease slightly the creep rate of the aluminum. A metallographic examination of the creep specimens showed no microstructural changes that could be attributed to the alpha-particle bombardment.

NACA RM E7F10

ALTITUDE-WIND-TUNNEL INVESTIGATION OF THRUST AUGMENTATION OF A TURBOJET ENGINE. III - PERFORMANCE WITH TAIL-PIPE BURNING IN STANDARD-SIZE TAIL PIPE. William A. Fleming and Richard L. Golladay. August 11, 1947. 47p. diagrs., photos. (NACA RM E7F10)

Thrust augmentation of a turbojet engine by burning fuel in the tail pipe has been investigated in the NACA Cleveland altitude wind tunnel. The engine performance was determined at several simulated flight conditions throughout the range of tail-pipe fuel flows. A tail-pipe combustion chamber having the same external dimensions as the standard turbojet engine tail pipe was investigated to determine whether satisfactory operation could be obtained at high-speed and high-altitude flight conditions. Two different flame holders were used.

NACA RM E7F11

COMBUSTION-EFFICIENCY INVESTIGATION OF SPECIAL FUELS IN SINGLE TUBULAR-TYPE COMBUSTOR AT SIMULATED ALTITUDE CONDITIONS. Ralph T. Dittrich. August 15, 1947. 25p. diagrs., 2 tabs. (NACA RM E7F11)

Ten special straight-run distillate fuels were investigated. The distillates were obtained from various crude oils and consisted of hydrocarbon mixtures with distillation temperatures varying from 93° to 690° F. Three commercial fuels were also tested. The operating conditions simulated engine operation at an altitude of 40,000 feet at engine speeds of 7000 and 10,500 rpm. Under certain operating conditions the flame extended beyond the turbine position. The tests showed that as the distillation temperature of the fractions from the same crude increased, the combustion efficiency decreased.

NACA RM E7F12

FUEL INVESTIGATION IN A TUBULAR-TYPE COMBUSTOR OF A TURBOJET ENGINE AT SIMULATED ALTITUDE CONDITIONS. Adelbert O. Tischler and Ralph T. Dittrich. August 1, 1947. 41p. diagrs., photo., 2 tabs. (NACA RM E7F12)

A series of 11 fuels, which ranged in volatility from gasoline to Diesel oil and which included hydrocarbons of the paraffinic, naphthenic, olefinic, and aromatic types, was tested in a single tubular combustion chamber of a turbojet engine under inlet-air conditions that simulated engine operation at two engine speeds at an altitude of 40,000 feet. Tests were also conducted at two additional inlet-air conditions. Temperature-rise data at various fuel-air ratios were obtained for each set of air-flow conditions.

NACA RM E7G03

EXPERIMENTAL INVESTIGATION OF PERFORMANCE AND OPERATING CHARACTERISTICS OF A TAIL-PIPE BURNER FOR A TURBOJET ENGINE. David S. Gabriel, E. Vincent Martinson and Robert H. Essig. October 30, 1947. 29p. diagrs. (NACA RM E7G03)

Presents description and operating characteristics of 10 full-scale tail-pipe burners. The combustion and pressure-drop characteristics of most satisfactory burner were investigated. A tail-pipe burner was developed that operated satisfactorily over a range of fuel-air ratios with inlet conditions of gas temperature and velocity simulating those in a typical turbojet engine.

NACA RM E7I25a

AN ANALYSIS OF CONTROL REQUIREMENTS AND CONTROL PARAMETERS FOR DIRECT-COUPLED TURBOJET ENGINES. David Novik and Edward W. Otto. February 18, 1948. 50p. diagrs. (NACA RM E7I25a)

Presents discussion of control parameters for direct-coupled turbojet engine, based on analysis of steady-state operation, acceleration, and deceleration, and describes operation of a hypothetical control system.

NACA RM E7J19

EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF 4000-POUND-THRUST CENTRIFUGAL-FLOW-TYPE TURBOJET ENGINE BY INJECTION OF WATER AND ALCOHOL AT COMPRESSOR INLETS. William L. Jones and Helmuth W. Engelman. May 14, 1948. 23p. diagrs. (NACA RM E7J19)

Contains curves and data to determine amount of thrust augmentation obtainable by injection of various water and alcohol mixtures at compressor inlets of a 4000-pound-thrust turbojet engine at standard NACA conditions. A maximum thrust augmentation of 26 percent was obtained by injection of 4.5 pounds per second of water and 2.0 pounds per second of alcohol.

NACA RM E7K14

EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF AXIAL-FLOW-TYPE 4000-POUND-THRUST TURBOJET ENGINE BY WATER AND ALCOHOL INJECTION AT COMPRESSOR INLET. Burnett Baron, Harry W. Dowman and William C. Dackis. July 8, 1948. 41p. diagrs., photos. (NACA RM E7K14)

Reports on experimental investigation of thrust augmentation of axial-flow-type turbojet engine with a 4000-pound-thrust rating by means of water-alcohol injection at the compressor inlet. Augmentation was limited by centrifugal separation of liquid and air in the compressor and was sensitive to engine inlet-air temperature. A thrust augmentation of 15.4 percent was obtained with injection of 3 pounds per second of water alone at an inlet-air temperature of 548° F.

NACA RM E7L12

RELATION OF NOZZLE-BLADE AND TURBINE-BUCKET TEMPERATURES TO GAS TEMPERATURES IN A TURBOJET ENGINE. J. Elmo Farmer. April 30, 1948. 37p. diagrs., photos. (NACA RM E7L12)

Presents results of investigation to determine experimentally turbine-nozzle-blade and turbine-bucket temperatures in a turbojet engine and to correlate these temperatures with gas temperatures. Maximum indicated temperatures were about 1900° F for the nozzle blade and 1500° F for the turbine bucket. The maximum turbine-nozzle-blade temperature was 80° to 270° F higher than the calculated average turbine-inlet-gas temperature; the maximum turbine-bucket temperature was about 150° F less than the calculated average turbine-inlet-gas temperature.

NACA RM E7L16

ALTITUDE-WIND-TUNNEL INVESTIGATION OF THRUST AUGMENTATION OF A TURBOJET ENGINE. IV - PERFORMANCE WITH TAIL-PIPE BURNING AND WATER INJECTION. Robert O. Dietz, Jr., George Wishnek and John K. Kuenzig. June 15, 1948. 31p. diagrs., photo. (NACA RM E7L16)

Results of investigation of thrust augmentation of axial-flow-type turbojet engine by combination of tail-pipe burning and water injection are presented. Thrust increases obtainable with engine-inlet water injection reached a peak at a water-air ratio of 0.035 and decreased with larger amounts of injection; whereas thrust increases obtainable with combustion-chamber water injection increased as water-air ratio was raised throughout range of water-air ratios investigated. Greater maximum thrust increases were available with combustion-chamber water injection than with engine-inlet water injection. Thrust increases were accompanied by large increases in specific liquid consumption.

NACA RM E7L17

CONTROL DURING STARTING OF GAS-TURBINE ENGINES. Robert J. Koenig and Marcel Dandois. June 17, 1948. 39p. diagrs., photos. (NACA RM E7L17)

Reports on investigation of variables pertinent to the control of gas temperatures during starting of gas-turbine engines. Results indicate that poor control of gas temperatures during starting is caused by an accumulation of fuel in the engine before ignition and by excessive fuel-flow rates at the time of ignition. Prompt ignition was obtained by use of well atomized fuel sprays.

NACA RM E7L18

VIBRATION OF TURBINE BLADES IN A TURBOJET ENGINE DURING OPERATION. W. C. Morgan, R. H. Kemp and S. S. Manson. April 22, 1948. 17p. diagrs., photos. (NACA RM E7L18)

An experimental investigation was made to determine the vibration phenomena that occur in gas-turbine blades during service operation. Through the use of high-temperature strain gages, vibratory phenomena in turbine blades were observed and evaluated in terms of modes, frequencies, and stress range. The frequencies of the principal vibrations were found to be related to the number of nozzle blades and combustion chambers.

NACA RM E7L30

COMBUSTION-EFFICIENCY AND ALTITUDE-LIMIT INVESTIGATIONS OF FIVE FUELS IN AN ANNULAR TURBOJET COMBUSTOR. Jerrold D. Wear and Edmund R. Jonash. June 7, 1948. 19p. diagrs. (NACA RM E7L30)

Five fuels of various boiling temperatures and various hydrocarbon types were investigated in a jet-propulsion annular combustor of 10-3/8 inch diameter to determine the effect of boiling temperature and paraffinic and aromatic hydrocarbon types on combustion efficiency and altitude operational limit at three inlet-air conditions. The performance difference among the fuels was greatest at inlet-air conditions characterized by unstable combustion.

NACA RM E8A28a

BENCH AND ENGINE OPERATION OF A FUEL-DISTRIBUTION CONTROL. Harold Gold and Robert J. Koenig. June 14, 1948. 34p. diagrs., photos. (NACA RM E8A28a)

Presents application of a fuel-distribution-control method to actual gas-turbine engine operation. The control used was designed to equalize the flow to the 14 nozzles of a gas-turbine engine. The maximum measured deviation from perfect distribution during engine operation was 3.8 percent. It was shown that the control model is capable of maintaining this accuracy independently of changes in fuel-nozzle resistances from 0 up to 1.46 times the resistance of a normal engine fuel nozzle.

NACA RM E8C02a

EFFECT OF FUELS AND FUEL-NOZZLE CHARACTERISTICS ON PERFORMANCE OF AN ANNULAR COMBUSTOR AT SIMULATED ALTITUDE CONDITIONS. Richard J. McCafferty. September 28, 1948. 90p. diagrs., photos., tab. (NACA RM E8C02a)

The effect of fuels and fuel-nozzle characteristics on performance of an annular combustor at simulated altitude conditions was determined by operating with different fuels and fuel-nozzle sizes with the combustor inlet-air conditions each independently altered near the altitude operational limits. Results indicate that amount of difference in performance at altitude among different fuels is determined by hydrocarbon type and fuel boiling points. Reduction in fuel-nozzle size increased combustion efficiency at low heat-input values but produced lower temperature-rise limits.

NACA RM E8C08

A FUEL-DISTRIBUTION CONTROL FOR GAS-TURBINE ENGINES. Harold Gold and David M. Straight. June 14, 1948. 17p. diagrs., photos. (NACA RM E8C08)

A device to control the distribution of fuel to any number of discharge nozzles of a gas-turbine engine is presented. A model of the device controlled the flow to four discharge nozzles within 2 percent of perfect distribution over a wide range of fuel flows and was unaffected by uneven discharge-nozzle pressures.

NACA RM E8D12

INVESTIGATION OF HIGH-TEMPERATURE OPERATION OF LIQUID-COOLED GAS TURBINES. I - TURBINE WHEEL OF ALUMINUM ALLOY, A HIGH-CONDUCTIVITY NONSTRATEGIC MATERIAL. Harry Kottas and Bob W. Sheflin. July 22, 1948. 15p. diagrs., photos., tab. (NACA RM E8D12)

A liquid-cooled gas turbine with aluminum-alloy blades and disk was built to investigate the effect of liquid cooling and high-conductivity metals on limiting turbine-inlet gas temperature. The turbine was successfully operated at a speed of 19,000 rpm and an inlet gas temperature of 2100° F.

NACA RM E8D14

GAS-TURBINE-ENGINE OPERATION WITH VARIABLE-AREA FUEL NOZZLE. Harold Gold and David M. Straight. July 9, 1948. 47p. diagrs., photos. (NACA RM E8D14)

The characteristics of variable-area and fixed-area atomizing nozzles are discussed in relation to use in aircraft gas-turbine engines. A variable-area nozzle and a fuel-distribution control that were used in the operation of a gas-turbine engine are described. When the engine was equipped with variable area fuel nozzles, thrust specific fuel consumption in the lower half of the fuel-flow range was reduced, fuel pressures were lowered in the upper half of the fuel-flow range, and starting characteristics were improved.

NACA RM E8D23

PERFORMANCE OF SEVERAL AIR EJECTORS WITH CONICAL MIXING SECTIONS AND SMALL SECONDARY FLOW RATES. S. C. Huddleston, H. D. Wilsted and C. W. Ellis. July 19, 1948. 74p. diagrs. (NACA RM E8D23)

Experimental results presented are limited to investigations of conical-type mixing-section ejectors at ratios of mixing-section minimum diameter to primary-jet-nozzle diameter of 1.21, 1.10, and 1.00 using unheated air. Results were cross-plotted in charts to show the performance of all ejectors within the range of configurations investigated. For diameter ratios of 1.21 and 1.10, the spacing giving maximum airflow varied with diameter ratio but did not vary with primary and secondary pressure ratios. In general, the ejector had little effect on the primary nozzle thrust.

NACA RM E8D29

EFFECT OF MACH NUMBER ON PERFORMANCE OF AN AXIAL-FLOW COMPRESSOR ROTOR-BLADE ROW. Paul D. Dugan, John J. Mahoney and William A. Benser. September 28, 1948. 27p. diagrs., photo. (NACA RM E8D29)

An investigation was conducted to study the influence of high relative inlet Mach number on the performance of a highly loaded rotor blade row. A range of weight flow was investigated for equivalent tip speeds ranging from 300 to 915 feet per second, which correspond to relative inlet Mach numbers of 0.30 to 0.90 at the mean radius. At high Mach numbers, above 0.70, the blade-section-performance results of this investigation indicated good correlation with low-speed cascade results. The efficiency gradually decreased from 0.950 to 0.915 as the relative inlet Mach number increased from 0.30 to 0.82.

NACA RM E8E10

ANALYTICAL INVESTIGATION OF EFFECT OF WATER-COOLED TURBINE BLADES ON PERFORMANCE OF TURBINE-PROPELLER POWER PLANTS. William D. Bowman. August 16, 1948. 67p. diagrs. (NACA RM E8E10)

Performance of six turbine-propeller power plants, each having a multistage turbine equipped with water-cooled turbine blades and designed for maximum turbine inlet temperatures of 2000°, 2500°, 3000°, 4000°, and 4500° R, respectively, is calculated over a range of flight speeds from 200 to 600 miles per hour at altitudes from sea level to 35,000 feet. High temperature operation possible with water-cooled blades yields, at appropriate pressure ratios, performance gains that are not vitiated by losses incurred in cooling process. The heat-exchanger capacity and size are approximately 20 percent of that of a liquid-cooled piston engine of equal rated power.

NACA RM E8F04

DESIGN AND PERFORMANCE OF EXPERIMENTAL AXIAL-DISCHARGE MIXED-FLOW COMPRESSOR. I - IMPELLER DESIGN THEORY. Arthur W. Goldstein. August 12, 1948. 32p. diagrs. (NACA RM E8F04)

An axial-discharge centrifugal compressor, especially adapted for jet engines because of the large mass flow per unit frontal area, is described. General equations of relative fluid motion are developed to show assumptions involved and empirical character of simplifications. The best impeller was selected on basis of maximum air-flow capacity, which was 19.6 pounds per second for 14-inch diameter with tip speed of 1480 feet per second and pressure ratio of 3.5.

NACA RM E8F09

ALTITUDE-WIND-TUNNEL INVESTIGATION OF A 4000-POUND-THRUST AXIAL-FLOW TURBOJET ENGINE. I - PERFORMANCE AND WINDMILLING DRAG CHARACTERISTICS. William A. Fleming. August 3, 1948. 76p. diagrs., photos. (NACA RM E8F09)

Performance of a 4000-pound-thrust axial-flow turbojet engine was investigated at altitudes from 5000 to 40,000 feet and at ram pressure ratios from 1.02 to 1.86. The specific fuel consumption based on net thrust horsepower decreased rapidly with airspeed. Windmilling drag of the engine was relatively high and the inlet should be closed when the engine is inoperative in flight. The results show that an accurate calculation of the jet thrust of the engine can be made from measurements of the temperatures and pressures obtained from a survey across the jet-nozzle exit.

NACA RM E8F09a

ALTITUDE-WIND-TUNNEL INVESTIGATION OF A 4000-POUND-THRUST AXIAL-FLOW TURBOJET ENGINE. II - OPERATIONAL CHARACTERISTICS. William A. Fleming. August 6, 1948. 53p. diagrs., photos., 3 tabs. (NACA RM E8F09a)

Operational characteristics of a 4000-pound-thrust axial-flow turbojet engine were obtained at pressure altitudes from 5000 to 50,000 feet, ram pressure ratios from 1.00 to 1.86, and temperatures from 60° to -50° F. The effects of altitude and airspeed on such operational characteristics as combustion stability acceleration, starting, and fuel-control system were studied. The engine could be operated at full speed without serious burner unbalance at altitudes up to 50,000 feet. Acceleration of the engine was relatively slow and the time required for acceleration increased with altitude. The engine started normally and easily below 20,000 feet.

NACA RM E8F09b

ALTITUDE-WIND-TUNNEL INVESTIGATION OF A 4000-POUND-THRUST AXIAL-FLOW TURBOJET ENGINE. III - PERFORMANCE CHARACTERISTICS WITH THE HIGH-FLOW COMPRESSOR. William A. Fleming and Richard L. Golladay. August 5, 1948. 69p. diagrs., photos. (NACA RM E8F09b)

An investigation was conducted to determine the performance of a 4000-pound-thrust axial-flow turbojet engine with a high-flow compressor at altitudes from 5000 to 40,000 feet and ram pressure ratios from 1.00 to 1.82. Engine performance with high-flow and low-flow (standard) compressors is compared. Installation of a high-flow compressor in the engine in place of a low-flow compressor at a corrected engine speed of 7600 rpm and a ram pressure ratio of 1.40 gave an increase in corrected jet thrust of 11 percent, in corrected net thrust of 6.5 percent, in corrected fuel consumption of 14 percent, and in corrected airflow of 12 percent.

NACA RM E8F09c

ALTITUDE-WIND-TUNNEL INVESTIGATION OF A 4000-POUND-THRUST AXIAL-FLOW TURBOJET ENGINE. IV - ANALYSIS OF COMPRESSOR PERFORMANCE. Robert O. Dietz, Jr. and Frank L. Suozzi. August 5, 1948. 54p. diagrs., photos., tab. (NACA RM E8F09c)

Performance of two 11-stage axial-flow compressors operating in a 4000-pound-thrust axial-flow turbojet engine was investigated at simulated altitudes from 5000 to 40,000 feet, ram pressure ratios from 1.00 to 1.86, and compressor Mach numbers from 0.24 to 0.95. One was a standard compressor and the other, a similar compressor except that the blade angles of the rotor and stator blades were increased about 5° to obtain greater airflow. Maximum adiabatic efficiency for both compressors was about 85 percent. Increasing the blade angles 5° increased the airflow approximately 10 percent. Efficiency and pressure ratio at a given compressor Mach number were unaffected by changes in Reynolds number.

NACA RM E8F09d

ALTITUDE-WIND-TUNNEL INVESTIGATION OF A 4000-POUND-THRUST AXIAL-FLOW TURBOJET ENGINE. V - ANALYSIS OF TURBINE PERFORMANCE. Richard P. Krebs and Reece V. Hensley. August 4, 1948. 27p. diagrs., photo. (NACA RM E8F09d)

Performance characteristics of a turbine from a 4000-pound-thrust axial-flow turbojet engine were obtained at altitudes from 5000 to 40,000 feet and at ram pressure ratios from 1.01 to 1.77. Turbine efficiency was practically unaffected by changes in altitude or ram pressure ratio. The maximum efficiency obtained was about 82 percent.

NACA RM E8F17

PERFORMANCE INVESTIGATION OF CAN-TYPE COMBUSTOR. I - INSTRUMENTATION, ALTITUDE OPERATIONAL LIMITS AND COMBUSTION EFFICIENCY. Eugene V. Zettle and William P. Cook. September 16, 1948. 21p. diagrs., photo., tab. (NACA RM E8F17)

Investigation of single can-type combustor of turbojet engine was conducted to determine altitude operational limits with two fuels, combustion efficiencies at various altitudes and engine speeds, combustor-outlet temperature distribution, and combustor total-pressure drop. Limits with AN-F-32 fuel were approximately 60,000 feet for engine speed of 6000 rpm and 38,000 feet for engine speed of 4000 rpm. Altitude operational limits with AN-F-32 fuel are higher over largest part of engine-speed range than with AN-F-28 fuel.

NACA RM E8F29

OPERATING TEMPERATURES OF I-40-5 TURBOJET ENGINE BURNER LINERS AND THE EFFECT OF TEMPERATURE VARIATION ON BURNER-LINER SERVICE LIFE. H. D. Wilsted, Robert T. Duffy and Ralph E. Grey. August 23, 1948. 25p. diagrs., photos. (NACA RM E8F29)

The metal temperature and the temperature distribution in an I-40-5 turbojet engine were determined over the operating range of engine speeds using thermocouples welded to the outer surface of the burner liner. A ceramic-coated thermocouple was used throughout the investigation. Burner-liner temperatures increased at an increasing rate with engine speed; the highest temperature recorded was 1500° F. Temperature gradients were as large as 700° F per inch. The high local temperature gradients were apparently the cause of short burner-liner service life.

NACA RM E8G02

INVESTIGATION OF THE I-40 JET-PROPULSION ENGINE IN THE CLEVELAND ALTITUDE WIND TUNNEL. I - PERFORMANCE AND WINDMILLING DRAG CHARACTERISTICS. Stanley L. Gendler and William K. Koffel. August 24, 1948. 75p. diagrs., photos. (NACA RM E8G02)

An altitude-wind-tunnel investigation of the performance and windmilling characteristics of an I-40 jet-propulsion engine was conducted over a range of simulated flight conditions to determine the effects of altitude and ram pressure ratio. The use of generalizing factors for estimating altitude performance of the engine gave only fair results. Specific fuel consumption based on net thrust horsepower showed no effect of altitude but decreased with increasing ram pressure ratio at an engine speed of 11,500 rpm.

NACA RM E8G02a

INVESTIGATION OF THE I-40 JET-PROPULSION ENGINE IN THE CLEVELAND ALTITUDE WIND TUNNEL. II - ANALYSIS OF COMPRESSOR PERFORMANCE CHARACTERISTICS. Robert O. Dietz, Jr. and Robert M. Geisenheyner. August 26, 1948. 28p. diagrs., photos. (NACA RM E8G02a)

Performance characteristics of a centrifugal compressor operating as an integral part of a jet propulsion engine were obtained for a range of compressor Mach numbers from 0.72 to 1.46, ram pressure ratios from 0.98 to 1.76, and simulated altitudes from 10,000 to 40,000 feet. From results obtained over a wide range of altitudes, it was determined that the compressor performance is primarily dependent on the compressor-inlet Mach number. Variations of Reynolds number of the air at the compressor inlet had little effect on compressor performance.

NACA RM E8G02b

INVESTIGATION OF THE I-40 JET-PROPULSION ENGINE IN THE CLEVELAND ALTITUDE WIND TUNNEL. III - ANALYSIS OF TURBINE PERFORMANCE AND EFFECT OF TAIL-PIPE DESIGN ON ENGINE PERFORMANCE. Richard P. Krebs and Frederick C. Foshag. August 26, 1948. 27p. diagrs., photo. (NACA RM E8G02b)

Performance characteristics of a turbine operating as an integral part of a jet-propulsion engine were determined for a range of simulated altitudes from 10,000 to 40,000 feet and ram pressure ratios from 0.98 to 1.76. A comparison of engine performance with three different tail pipes is also presented. Turbine efficiency was unaffected by changes in altitude or the tail-pipe designs but varied with changes in ram pressure ratio. The most satisfactory engine performance was obtained with a constant-diameter tail pipe having a short nozzle at the outlet.

NACA RM E8G02c

INVESTIGATION OF THE I-40 JET-PROPULSION ENGINE IN THE CLEVELAND ALTITUDE WIND TUNNEL. IV - ANALYSIS OF COMBUSTION-CHAMBER PERFORMANCE. Reece V. Hensley. August 25, 1948. 34p. diagrs. (NACA RM E8G02c)

Combustion-chamber performance characteristics have been determined from an I-40 jet-propulsion engine over a range of simulated altitudes and ram pressure ratios. Combustion efficiency varied directly with ram pressure ratio and engine speed and varied inversely with altitude. Percentage losses in total pressure were appreciably affected by changes in altitude or ram pressure ratio up to a value of 1.3.

NACA RM E8G02d

INVESTIGATION OF THE I-40 JET-PROPULSION ENGINE IN THE CLEVELAND ALTITUDE WIND TUNNEL. V - OPERATIONAL CHARACTERISTICS. Richard L. Golladay and Stanley L. Gendler. August 25, 1948. 71p. diagrs., photos., 6 tabs. (NACA RM E8G02d)

Operational characteristics of a jet-propulsion engine determined at pressure altitudes from 10,000 to 50,000 feet and ram pressure ratios from 1.00 to 1.76 include effects of altitude and airspeed on operating speed range, starting, windmilling, acceleration, speed regulation, cooling, and vibration of the standard and modified engines. Maximum engine speed was obtainable at all altitudes and airspeeds with each fuel-control system investigated. The maximum idling speed was raised by increases in altitude and airspeed. Ignition at 30,000 feet was difficult. Windmilling starts were not successful. The engine speed was held constant during simulated dives and climbs at constant throttle position.

NACA RM E8H11

THEORETICAL COMPARISON OF SEVERAL METHODS OF THRUST AUGMENTATION FOR TURBOJET ENGINES. Eldon W. Hall and E. Clinton Wilcox. October 27, 1948. 40p. diagrs. (NACA RM E8H11. Now issued as Rept. 992)

Performance of several methods of thrust augmentation for turbojet engines was calculated for flight Mach numbers from 0 to 2.5 and for altitudes of sea level and 35,332 feet. The methods investigated were tail-pipe burning, water injection at compressor inlet, combination of tail-pipe burning and water injection, bleedoff, and rocket assist. Results indicated that tail-pipe burning plus water injection was best for large amounts of thrust augmentation and tail-pipe burning was best for smaller amounts inasmuch as these methods have the lowest ratio of augmented-to-normal total liquid consumption for a given thrust increase.

NACA RM E8H12

DETERMINATION OF AVERAGE HEAT-TRANSFER COEFFICIENTS FOR A CASCADE OF SYMMETRICAL IMPULSE TURBINE BLADES. I - HEAT TRANSFER FROM BLADES TO COLD AIR. Gene L. Meyer. 41p. diagrs., photos. (NACA RM E8H12)

A cascade of symmetrical impulse turbine blades was investigated to determine average surface heat-transfer coefficients. The results were correlated with other cascade data for impulse blades and are presented in dimensionless form. Heat-transfer coefficients based on an effective gas temperature were independent of Mach number.

NACA RM E8I03

EFFECT OF PRESSURE RATIO AND INLET PRESSURE ON PERFORMANCE OF EXPERIMENTAL GAS TURBINE AT INLET TEMPERATURE OF 800° R. Robert C. Kohl and Robert G. Larkin. November 22, 1948. 7p. diagrs. (NACA RM E8I03)

An experimental gas turbine was operated over a range of blade-jet speed ratios, total pressure ratios, and inlet total pressures at a constant inlet temperature of 800° R. Peak over-all efficiencies were obtained at blade-jet speed ratios from 0.525 to 0.575 for all runs. The variation in peak efficiency with inlet pressure and pressure ratio was of small magnitude for the conditions investigated.

NACA RM E8I21

SOME EFFECTS OF STATOR CONE ANGLE AND BLADE-TIP LEAKAGE ON 40-PERCENT-REACTION TURBINE HAVING ROTOR-BLADE CAPS. Robert E. English, Robert J. McCready and John S. McCarthy. March 23, 1949. 28p. diagrs., photo. (NACA RM E8I21)

A turbine having 40-percent reaction and rotor-blade caps, which form a continuous rotating cylindrical shroud, was operated with two stators having cone angles of 70° and 0° and with two stationary shrouds—a labyrinth, no-leakage shroud and a cylindrical shroud. With the 0°-cone-angle stator, the efficiency was 0.04 higher than with the 70°-cone-angle stator. Replacing the labyrinth shroud with the cylindrical shroud having a radial clearance 0.016 of the blade height produced no measurable change in efficiency.

NACA RM E8J22

VIBRATION SURVEY OF BLADES IN 10-STAGE AXIAL-FLOW COMPRESSOR. I - STATIC INVESTIGATION. Andre J. Meyer, Jr. and Howard F. Calvert. January 31, 1949. 34p. diagrs., photos., 2 tabs. (NACA RM E8J22)

Natural frequencies were measured in the blading of a 10-stage axial-flow compressor and these frequencies were compared with possible exciting forces. Node shapes of higher modes of vibration were determined from sand patterns in an attempt to correlate the position of high-stress points for the various modes with the location of actual failures in the seventh- and tenth-stage blades. Critical-speed diagrams were plotted to show possible cause of failures.

NACA RM E8J22a

VIBRATION SURVEY OF BLADES IN 10-STAGE AXIAL-FLOW COMPRESSOR. II - DYNAMIC INVESTIGATION. Andre J. Meyer, Jr. and Howard F. Calvert. January 31, 1949. 25p. diagrs., photos. (NACA RM E8J22a)

Vibratory stresses were measured in the first five stages by the use of strain gages mounted on the blades of a 10-stage axial-flow compressor. Effects of surge and of changes in pressure ratio on amplitude of blade vibrations were investigated. Good correlation was obtained between first bending-mode frequencies that were dynamically measured and those that were calculated by correcting static measurements to account for the effects of centrifugal force.

NACA RM E8J22b

VIBRATION SURVEY OF BLADES IN 10-STAGE AXIAL-FLOW COMPRESSOR. III - PRELIMINARY ENGINE INVESTIGATION. Andre J. Meyer, Jr. and Howard F. Calvert. January 31, 1949. 23p. diagrs., photo. (NACA RM E8J22b)

Vibratory stresses were measured in the blading of a 10-stage axial-flow compressor under operating conditions. Curves are presented showing maximum allowable vibratory stress for a given speed, change of damping coefficient with mounting of a strain gage at base of blade, effect of rotor speed on blade natural frequency, and effect of order of the first bending-mode vibration on stress. For all stages, the lower the order of vibration the higher the stress but no destructive vibrations were detected.

NACA RM E8J25

ALTITUDE-WIND-TUNNEL INVESTIGATION OF OPERATIONAL CHARACTERISTICS OF WESTINGHOUSE X24C-4B AXIAL-FLOW TURBOJET ENGINE. W. Kent Hawkins and Carl L. Meyer. November 23, 1948. 39p. diagrs., photos. (NACA RM E8J25)

Operating characteristics of Westinghouse X24C-4B axial-flow turbojet engine presented include: Operable engine-speed range at altitude, acceleration and deceleration, altitude and flight-Mach-number compensation of governor, lubrication-system performance, and starting characteristics. Operable range of engine speeds was limited at high altitudes and low flight Mach numbers. Accelerations and decelerations at altitudes above 25,000 feet were limited by combustion blow-out. Altitude and flight-Mach-number compensation of governor was good at high engine speeds and starting characteristics of one engine configuration were very unsatisfactory.

NACA RM E8J25a

ALTITUDE-WIND-TUNNEL INVESTIGATION OF PERFORMANCE AND WINDMILLING DRAG CHARACTERISTICS OF WESTINGHOUSE X24C-4B AXIAL-FLOW TURBOJET ENGINE. Carl L. Meyer and Harry E. Bloomer. November 23, 1948. 60p. diagrs., photo. (NACA RM E8J25a)

An altitude-wind-tunnel investigation of the performance and windmilling drag characteristics of an original and a modified turbojet engine was conducted over a range of simulated flight conditions. Performance variables depending upon fuel consumption that are obtained from data at one altitude cannot be used to predict these variables at other altitudes; however, thrust and air-flow values can be predicted for a limited range of altitudes from data taken at one altitude. The maximum net thrust of the modified engine was 3 to 20 percent greater than that of the original engine. The windmilling engine speed and drag of the two engines were comparable.

NACA RM E8J25d

INVESTIGATION OF PERFORMANCE OF TURBOJET ENGINE WITH CONSTANT- AND VARIABLE-AREA EXHAUST NOZZLES. Lewis E. Wallner. November 26, 1948. 43p. diagrs., photos., tab. (NACA RM E8J25d)

Presents performance of turbojet engine with constant- and variable-area exhaust nozzles at simulated altitudes from 5000 to 45,000 feet and simulated flight Mach numbers from 0.12 to 0.94. The efficiency of the variable-area nozzle investigated was 1.5 to 8 percent lower than the efficiency of the constant-area nozzle. As a result, lower thrusts and specific fuel consumptions were obtained with the variable-area nozzle as compared to the constant-area nozzle.

NACA RM E8J25e

ALTITUDE-WIND-TUNNEL INVESTIGATION OF TAIL-PIPE BURNING WITH A WESTINGHOUSE X24C-4B AXIAL-FLOW TURBOJET ENGINE. William A. Fleming and Lewis E. Wallner. December 13, 1948. 56p. diagrs., photos., tab. (NACA RM E8J25e)

Thrust augmentation of a 3000-pound-thrust axial-flow type turbojet engine by burning fuel in the tail pipe has been investigated in the NACA Cleveland altitude wind tunnel. The highest net-thrust increase obtained in the investigation was 86 percent with a net thrust specific fuel consumption of 2.91 and a total fuel-air ratio of 0.0523. The highest combustion efficiencies obtained with each of the four configurations investigated ranged from 0.71 to 0.96.

NACA RM E8J28

ALTITUDE-WIND-TUNNEL INVESTIGATION OF WESTINGHOUSE 19B-2, 19B-8, AND 19XB-1 JET-PROPULSION ENGINES. I - OPERATIONAL CHARACTERISTICS. William A. Fleming. 21p. diagrs., photos. (NACA RM E8J28)

Operational characteristics of the 19B-2, 19B-8, and 19XB-1 turbojet engines discussed include effects of altitude and airspeed on operating range, combustion stability, starting, acceleration, and functioning of fuel-control system. Operation of 19B engines above an altitude of 17,000 feet was limited because of combustion blow-out; operational range of the 19XB-1 engine was slightly better than that of 19B engines. Starting characteristics of the 19XB-1 engine were satisfactory but 19B engines did not start consistently.

NACA RM E8J28a

ALTITUDE-WIND-TUNNEL INVESTIGATION OF WESTINGHOUSE 19B-2, 19B-8, AND 19XB-1 JET-PROPULSION ENGINES. II - ANALYSIS OF TURBINE PERFORMANCE OF 19B-8 ENGINE. Richard P. Krebs and Frank L. Suozzi. November 24, 1948. 27p. diagrs., photos. (NACA RM E8J28a)

The performance of the turbine of the 19B-8 turbojet engine was determined from an investigation of the complete engine in the altitude wind tunnel over a range of simulated flight conditions. The effects of altitude, flight Mach number, and tail-cone position on turbine performance are discussed. Turbine efficiency was unaffected by changes in altitude up to 15,000 feet but was a function of tail-cone position and flight Mach number.

NACA RM E8J28b

ALTITUDE-WIND-TUNNEL INVESTIGATION OF WESTINGHOUSE 19B-2, 19B-8, AND 19XB-1 JET-PROPULSION ENGINES. III - PERFORMANCE AND WINDMILLING DRAG CHARACTERISTICS. William A. Fleming and Robert O. Dietz, Jr. November 26, 1948. 71p. diagrs., photos. (NACA RM E8J28b)

Performance of the 19B-8 and 19XB-1 turbojet engines and windmilling drag of the 19B-8 engine were determined in the altitude wind tunnel for a range of simulated flight conditions. Performance variables involving fuel consumption that are obtained from data at one altitude cannot be used to predict these variables at altitudes above 15,000 feet; thrust and air-flow values can be predicted for the range of altitudes investigated from data taken at one altitude. At similar operating conditions, corrected values of jet thrust and air flow were approximately the same for both engines.

NACA RM E8J28c

ALTITUDE-WIND-TUNNEL INVESTIGATION OF WESTINGHOUSE 19B-2, 19B-8, AND 19XB-1 JET-PROPULSION ENGINES. IV - ANALYSIS OF COMPRESSOR PERFORMANCE. Robert O. Dietz and John K. Kuenzig. November 26, 1948. 48p. diagrs., photos. (NACA RM E8J28c)

Performance of the compressors of the 19B-8 and 19XB-1 turbojet engines was determined from an investigation of the complete engines over a range of simulated flight conditions. For the range of compressor operation investigated, Reynolds number had no measurable effect on compressor performance. The operating lines of the 19B-8 compressor were on the low-air-flow side of the region of maximum efficiency. The pressure ratio of the 19XB-1 compressor was higher than that of the 19B-8 compressor.

NACA RM E8J28d

ALTITUDE-WIND-TUNNEL INVESTIGATION OF WESTINGHOUSE 19B-2, 19B-8, AND 19XB-1 JET-PROPULSION ENGINES. V - COMBUSTION-CHAMBER PERFORMANCE. Bemrose Boyd. November 26, 1948. 41p. diagrs., photo. (NACA RM E8J28d)

Combustion-chamber pressure losses of the 19B-2 and 19B-8 turbojet engines and combustion efficiencies of these two engines and the 19XB-1 turbojet engine are presented. Data were obtained from investigation of the complete engine over a range of simulated flight conditions. Maximum combustion efficiency was shifted to higher engine speeds by increasing altitude. Combustion efficiency was decreased at low engine speeds by increasing tunnel Mach number and was decreased at high engine speeds by extension of the tail cone.

NACA RM E8J29

SIMULATED ALTITUDE PERFORMANCE OF COMBUSTOR OF WESTINGHOUSE 19XB-1 JET-PROPULSION ENGINE. J. Howard Childs and Richard J. McCafferty. November 30, 1948. 44p. diagrs., photo., 2 tabs. (NACA RM E8J29)

A 19XB-1 combustor was operated under conditions simulating zero-ram operation of the 19XB-1 turbojet engine at various altitudes and engine speeds. The combustion efficiencies and the altitude operational limits were determined; data were also obtained on the character of the combustion, the pressure drop through the combustor, and the combustor outlet temperature and velocity profiles.

NACA RM E8K22

CARBON DEPOSITION OF 19 FUELS IN AN ANNULAR TURBOJET COMBUSTOR. Jerrold D. Wear and Edmund R. Jonash. February 3, 1949. 21p. diagrs., 2 tabs. (NACA RM E8K22)

Effects of fuel properties and change in simulated engine operating conditions on carbon deposition were evaluated in an annular turbojet combustor with a diameter of 10-3/8 inches. The fuels included hydrocarbons of the paraffinic, olefinic, and aromatic types as well as fuel mixtures. Carbon deposition increased with increase in boiling temperature of fuels of the same hydrocarbon type. Aromatic fuels deposited more carbon than the other types of fuel of the same boiling temperature. An empirical correlation of the carbon deposition and the boiling temperature and hydrogen-carbon weight ratio of the fuel was obtained.

NACA RM E8L02

COMPARISON OF FLIGHT PERFORMANCE OF AN-F-58 AND AN-F-32 FUELS IN J35 TURBOJET ENGINE. Loren W. Acker and Kenneth S. Kleinknecht. April 7, 1949. 15p. diagrs., photo., 2 tabs. (NACA RM E8L02)

Performance of fuels corresponding to specifications AN-F-58 and AN-F-32 was investigated in a J35 turbojet engine in flight. Comparatively, AN-F-58 fuel indicated slightly higher net thrust and fuel consumption, inferior blowout limits, and similar altitude starting characteristics and carbon deposits.

NACA RM E8L20a

ALTITUDE PERFORMANCE OF AN-F-58 FUELS IN J35-C-3 SINGLE COMBUSTOR. Edward G. Stricker and Warren D. Rayle. June 14, 1949. 21p. diagrs., 2 tabs. (NACA RM E8L20a)

Three fuel blends conforming to AN-F-58 specifications were tested in order to determine the influence of boiling temperatures and aromatic content on altitude performance in single combustor of 4000-pound-thrust turbojet engine. At simulated engine conditions from an altitude of 30,000 to an altitude of 60,000 feet and 85-percent rated engine speed, the three AN-F-58 fuels showed little difference in performance.

NACA RM E9B02

INVESTIGATION OF SEVERAL CLAMSHELL VARIABLE-AREA EXHAUST NOZZLES FOR TURBOJET ENGINES. Bruce T. Lundin. May 26, 1949. 52p. diagrs., photos. (NACA RM E9B02)

Efficiency of five different types of clamshell variable area exhaust nozzle for turbojet engines is compared with performance of various conventional fixed-area conical nozzles. Variable-area nozzles had satisfactory mechanical reliability even under afterburning conditions and three of the nozzles investigated provided jet thrust within 0 to 1-1/2 percent of that obtained with the fixed-area nozzles. Larger thrust losses for the other two nozzles were attributed principally to a nonplanar outlet configuration of the movable nozzle flaps.

NACA RM E9C15

TURBINE-ROTOR-BLADE DESIGNS BASED ON ONE-DIMENSIONAL-FLOW THEORY. I - PERFORMANCE OF SINGLE-STAGE TURBINE HAVING 40-PERCENT REACTION. Robert E. English and Cavour H. Hauser. June 10, 1949. 31p. diagrs., photo. (NACA RM E9C15)

The performance of the first of a family of turbine-rotor-blade designs is presented. The rotor blade was designed for a total-to-static pressure ratio of 4.00 and 40-percent reaction using one-dimensional-flow theory. Constant static pressure was assumed over the blade height at the entrance and the exit of each row of blades. The brake internal efficiency had a maximum value slightly greater than 0.84 and was equal to 0.82 at design conditions. For design conditions, the static pressure varied 5 percent over the blade height at the rotor exit.

NACA RM E9D01

EVALUATION OF PISTON-TYPE GAS-GENERATOR ENGINE FOR SUBSONIC TRANSPORT OPERATION. A. F. Lietzke and Hugh M. Henneberry. July 15, 1949. 29p. diagrs., tab. (NACA RM E9D01)

A piston-type gas-generator engine was evaluated by comparing performances of a transport airplane powered by this engine with an airplane having same characteristics powered by other types of engine. Turbojet, turbine-propeller, compound, and turbo-supercharged reciprocating engine were compared with gas-generator engine. Comparison is based on pay-load ton-miles per hour operation per ton take-off gross weight. Gas-generator engine was found to have a marked advantage over other engine types for long range at subsonic flight speeds. At short ranges no one engine showed great superiority, but the turbojet engine exhibits some advantages at high velocity.

NACA RM E9E16

EFFECT OF TEMPERATURE ON PERFORMANCE OF SEVERAL EJECTOR CONFIGURATIONS. H. D. Wilsted, S. C. Huddleston and C. W. Ellis. June 13, 1949. 27p. diagrs. (NACA RM E9E16)

An investigation was made to determine the effect of the primary-jet temperature on the performance of several ejector configurations. In general, for ejectors with short straight mixing lengths and short spacings, weight-flow ratio varies directly as the square root of ratio of total primary temperature to total secondary temperature. For ejectors with longer lengths and spacings, which pump greater weight flows through the secondary annulus, however, the pressure increase in the plane of the primary-nozzle exit decreases secondary weight flow so much that the temperature-ratio correction factor does not completely describe temperature effect on ejector performance.

NACA RM E9G01

PROPERTIES OF CERTAIN INTERMETALLICS AS RELATED TO ELEVATED-TEMPERATURE APPLICATIONS. I - MOLYBDENUM DISILICIDE. W. A. Maxwell. October 6, 1949. 27p. diagrs., 4 tabs. (NACA RM E9G01)

Methods were developed for the preparation, purification, and formation by pressing and sintering of molybdenum disilicide. The modulus-of-rupture strength and oxidation resistance at 2000° and 2400° F were studied as well as the general properties. Sintered molybdenum disilicide was found to have high comparative strength at 2400° F and to possess exceptional resistance to oxidation at high temperatures. The material deformed plastically at temperatures well below the melting point despite complete brittle behavior at room temperature.

NACA RM E9G08

ALTITUDE PERFORMANCE AND OPERATIONAL CHARACTERISTICS OF 29-INCH-DIAMETER TAIL-PIPE BURNER WITH SEVERAL FUEL SYSTEMS AND FLAME HOLDERS ON J35 TURBOJET ENGINE. E. William Conrad and William R. Prince. November 8, 1949. 50p. diagrs., photos., tab. (NACA RM E9G08)

An investigation of afterburning was conducted in the Lewis altitude wind tunnel using a full-scale turbojet engine to obtain information on afterburner design variables. Radial distribution and direction of injection of the tail-pipe fuel and several flame-holder types were studied. Direction of fuel injection had no effect on combustion efficiency; however, poor radial fuel distribution resulted in low combustion efficiencies. As altitude was increased, the decrease in peak combustion efficiency became more rapid as the blocking area of the flame holder was reduced. Problems of tail-pipe cooling and ignition are discussed and satisfactory solutions obtained.

NACA RM E9G13

CYCLIC ENGINE OPERATION OF CAST VITALLIUM TURBINE BLADES AT AN EXHAUST-CONE GAS TEMPERATURE OF 1440 ± 20° F. Charles Yaker and Floyd B. Garrett. September 19, 1949. 41p. diagrs., photos., 4 tabs. (NACA RM E9G13)

An investigation was conducted to study engine performance of cast Vitallium turbine blades at an estimated maximum blade temperature of 1600° F. The blades, mounted in a Timken 16-25-6 wheel, were subjected to 20-minute cycles consisting of approximately 5 minutes at idle and 15 minutes at rated speed. After 7-1/2 cycles (2 hr, 30 min), one

blade fractured due to fatigue, a large number of blades had intercrystalline cracks, and two blades had large transcrystalline cracks. Examination of broken and unbroken blades disclosed no correlation between blade failure and elongation as compared with grain size and hardness.

NACA RM E9G25

VIBRATIONAL MODES OF SEVERAL HOLLOW TURBINE BLADES AND OF SOLID TURBINE BLADE OF SIMILAR AERODYNAMIC DESIGN. R. H. Kemp and J. Shifman. October 3, 1949. 17p. diagrs., photos. (NACA RM E9G25)

Vibrational modes of several hollow turbine blades and a solid turbine blade of similar aerodynamic design were experimentally determined. Most of the observed vibrational modes of the hollow blades could be excited if the blades were operated in a conventional turbojet engine. A breathing effect was found in hollow blades at approximately 1230 cycles per second in which the blade walls moved toward each other and then away, producing stress concentrations at the leading and trailing edges. Little similarity in vibrational modes existed between the hollow blades and the solid blade. Approximately twice as many readily excited modes were found in the hollow blades as in the solid blade.

NACA RM E9I07

VIBRATION OF LOOSELY MOUNTED TURBINE BLADES DURING SERVICE OPERATION OF A TURBOJET ENGINE WITH CENTRIFUGAL COMPRESSOR AND STRAIGHT-FLOW COMBUSTION CHAMBERS. W. C. Morgan, R. H. Kemp and S. S. Manson. November 3, 1949. 18p. diagrs., photos. (NACA RM E9I07)

Vibration characteristics of loosely mounted turbine blades were determined during service operation of a turbojet engine. High-temperature strain gages were used to measure turbine-blade vibrations. Vibration occurred in first bending and first torsional modes; in addition, a small number of complex-mode vibrations was observed. Comparison was made between vibrations in loosely mounted blades and those observed during a previous investigation of similar blades tightly mounted in a turbine wheel. The comparison did not indicate that any considerable gain in damping was effected by the use of loosely mounted blades.

NACA RM E9I23

ALTITUDE-CHAMBER PERFORMANCE OF BRITISH ROLLS-ROYCE NENE II ENGINE. I - STANDARD 18.75-INCH-DIAMETER JET NOZZLE. Zelmar Barson and H. D. Wilsted. September 23, 1949. 58p. diagrs., 2 tabs. (NACA RM E9I23)

An altitude-chamber investigation of the British Rolls-Royce Nene II turbojet engine was conducted over a range of altitudes from sea level to 60,000 feet and ram-pressure ratios from 1.00 to 3.50. Decreasing compressor pressure ratio and efficiency at high altitude prevented prediction of engine performance parameters for altitudes above 20,000 feet from data obtained at any one altitude. Engine performance generalized to a single curve for ram-pressure ratio for all conditions when critical flow existed in the jet nozzle.

NACA RM E9K04

CORRELATION OF LABORATORY SMOKE TEST WITH CARBON DEPOSITION IN TURBOJET COMBUSTORS. Arthur M. Busch. February 3, 1950. 15p. diagrs., 3 tabs. (NACA RM E9K04)

A function of flame heights at the sooting point in a simple wick lamp and boiling point of 19 fuels was correlated with carbon deposition in a 10-3/8 inch annular turbojet combustor operating at a single set of conditions. Two similar investigations with different combustors, operating conditions, and nine different fuels yielded similar correlations. The simple wick lamp may be of value in the evaluation of turbojet fuels.

NACA RM E9L05

EFFECTS OF OBSTRUCTIONS IN COMPRESSOR INLET ON BLADE VIBRATION IN 10-STAGE AXIAL-FLOW COMPRESSOR. Andre J. Meyer, Jr., Howard F. Calvert and C. Robert Morse. February 13, 1950. 16p. diagrs. (NACA RM E9L05)

Resistance-wire strain gages were used to measure blade-vibration characteristics in 10-stage axial-flow compressor during normal jet-engine operation. Effects produced by obstructions in path of air flow entering compressor were also investigated. Aerodynamic damping of vibrating blades was evaluated. Results indicated that obstructions affected blade vibrations throughout compressor, that obstructions could be so located as to reduce some vibrations, and that aerodynamic damping accounted for about four-fifths of total dynamic blade damping.

NACA RM L6J09

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/16-SCALE MODEL OF THE D-558 RESEARCH AIRPLANE. LIFT AND DRAG CHARACTERISTICS OF THE D-558-I AND VARIOUS WING AND TAIL CONFIGURATIONS. John B. Wright and Donald L. Loving. April 18, 1947. 43p. diagrs., 2 tabs. (NACA RM L6J09)

Test results indicated the airplane will have satisfactory lift and drag characteristics up to and including the design Mach number of 0.85. The swept-wing and low-aspect-ratio wing configurations showed pronounced improvement in maintaining lift throughout the Mach number range tested and in increasing critical Mach numbers to the order of 0.9.

NACA RM L6K08

RESUME OF WIND-TUNNEL DATA ON THE EFFECT OF EXTERNAL STORES ON STABILITY OF MODELS OF MILITARY AIRPLANES. H. Norman Silvers and Raymond D. Vogler. December 19, 1946. 7p. 2 tabs. (NACA RM L6K08)

A summary, in tabular form, is presented on the effect on static stability of tanks, torpedoes, bombs, and radar domes. The data obtained indicate that at Mach numbers below 0.4 the effects of external stores on static longitudinal stability were small but may not be negligible. Although data were meager for Mach numbers above 0.4, results indicated that wing-tip tanks which were well faired to the wing contour caused reasonably small changes in static longitudinal stability. The available data were insufficient to estimate the general effects of external stores on lateral stability.

NACA RM L6K08b

PRELIMINARY TESTS OF A BURNER FOR RAM-JET APPLICATIONS. Paul W. Huber. January 15, 1947. 14p. diagrs. (NACA RM L6K08b)

Preliminary tests of a small ram-jet burner have been made and tests of this burner indicate efficient combustion characteristics (combustion was 80 percent complete) and low aerodynamic losses at the conditions tested. The fact that the measured combustion was so nearly complete is due mainly to the method of fuel injection and to mixing of fuel and air before ignition. The pressure drop due to frictional losses at the burner at the inner passage of the ram jet is small, since the air is not greatly disturbed to obtain mixing and ignition.

NACA RM L6L19

THE EFFECT OF HIGH SOLIDITY ON PROPELLER CHARACTERISTICS AT HIGH FORWARD SPEEDS FROM WIND-TUNNEL TESTS OF THE NACA 4-(3)(06.3)-06 AND NACA 4-(3)(06.4)-09 TWO-BLADE PROPELLERS. James B. Delano. February 27, 1947. 50p. diagrs., photos. (NACA RM L6L19)

Two two-blade propellers were tested in the Langley 8-foot high-speed tunnel through a range of blade angle from 20° to 70° for free-stream Mach numbers from 0.165 to 0.725 to determine the effects of high solidity and compressibility on propeller characteristics.

NACA RM L6L27

EFFECTS OF A FUSELAGE AND VARIOUS HIGH-LIFT AND STALL-CONTROL FLAPS ON AERODYNAMIC CHARACTERISTICS IN PITCH OF AN NACA 64-SERIES 40° SWEPT-BACK WING. D. William Conner and Robert H. Neely. May 26, 1947. 40p. diagrs., photos., tab. (NACA RM L6L27)

Wind-tunnel tests were made to determine low-speed lift, drag, and pitching-moment characteristics. The wing had an aspect ratio of 4 and a taper ratio of 0.625. Low-, middle-, and high-wing-fuselage combinations were tested at Reynolds numbers of 3×10^6 and 8.1×10^6.

NACA RM L7C11

AERODYNAMIC CHARACTERISTICS OF A 45° SWEPT-BACK WING WITH ASPECT RATIO OF 3.5 AND NACA 2S-50(05)-50(05) AIRFOIL SECTIONS. Anthony J. Proterra. August 4, 1947. 21p. diagrs., photo. (NACA RM L7C11)

Scale effects were investigated at Reynolds numbers ranging from 2.1×10^6 to 8.0×10^6; the effects of yaw were investigated at a Reynolds number of 4.1×10^6. Results indicate that the wing has poor characteristics from low-speed considerations.

NACA RM L7C24a

INVESTIGATION OF INTAKE DUCTS FOR A HIGH-SPEED SUBSONIC JET-PROPELLED AIRPLANE. Herbert N. Cohen. April 23, 1947. 24p. diagrs., photos., tab. (NACA RM L7C24a)

Results of pressure-loss measurements are presented for full-scale models of two ducts under consideration for use in the induction system of an experimental jet-propelled airplane. Supplementary pressure-loss measurements were made on the better of the two ducts, designated duct II, first with carborundum grains in the duct inlet and then with a spoiler in order to obtain an indication of the importance of inlet roughness and surface discontinuities. Additional measurements were made of duct II incorporating a horizontal "splitter" vane which was under consideration for structural reasons.

NACA RM L7D03

AN INVESTIGATION OF THE LOW-SPEED CHARACTERISTICS OF TWO SHARP-EDGE SUPERSONIC INLETS DESIGNED FOR ESSENTIALLY EXTERNAL SUPERSONIC COMPRESSION. John S. Dennard. June 6, 1947. 32p. diagrs., photos. (NACA RM L7D03)

The investigation has been conducted at low airspeeds to obtain preliminary information concerning the surface-pressure, drag, and pressure recovery of such inlets. Surface-pressure measurements and surveys of the pressures in the internal and external flow were obtained at angles of attack of 0° and 6° for a wide range of inlet-velocity ratio.

NACA RM L7D14

AERODYNAMIC CHARACTERISTICS OF A 42° SWEPT-BACK WING WITH ASPECT RATIO 4 AND NACA 64_1-112 AIRFOIL SECTIONS AT REYNOLDS NUMBERS FROM 1,700,000 TO 9,500,000. Robert H. Neely and D. William Conner. May 23, 1947. 39p. diagrs., photos. (NACA RM L7D14)

Wind-tunnel tests were made to determine low-speed aerodynamic characteristics in pitch and in yaw at high Reynolds numbers. The characteristics in pitch were obtained over a Reynolds number range from 1.7×10^6 to 9.5×10^6 and the characteristics in yaw from 1.7×10^6 to 5.3×10^6.

NACA RM L7E12

FURTHER INVESTIGATION OF NACA 4-(5)(08)-03 TWO-BLADE PROPELLER AT HIGH FORWARD SPEEDS. Melvin M. Carmel and Harold L. Robinson. May 26, 1947. 46p. diagrs. (NACA RM L7E12)

Tests of an NACA two-blade propeller have been made in the Langley 8-foot high-speed tunnel for blade angles of 45° and 60° extending the Mach number range from that of previous tests of this propeller up to a forward Mach number of 0.913.

NACA RM L7E13

EFFECTS OF A FUSELAGE ON THE AERODYNAMIC CHARACTERISTICS OF A 42° SWEPTBACK WING AT REYNOLDS NUMBERS TO 8,000,000. Reino J. Salmi, D. William Conner and Robert R. Graham. June 10, 1947. 32p. diagrs., photos. (NACA RM L7E13)

Tests were made in pitch at Reynolds numbers of 3,040,000 and 8,090,000 and in yaw at Reynolds numbers of 1,720,000 and 5,300,000. The wing had an aspect ratio of 4, a taper ratio of 0.625 and NACA 64_1-112 airfoil sections. Tests were made with the wing in high-, low-, and midwing positions. Tests were made without flaps and with 18.4-percent-chord split flaps extending from 12.3 to 50 percent of the semispan. The presence of the fuselage had little effect on the values of the maximum lift coefficient and the slope of the lift curve, but caused a destabilizing shift in the rate of change of pitching moment with lift.

NACA RM L7E23

LOW-SPEED CHARACTERISTICS IN PITCH OF A 42° SWEPTBACK WING WITH ASPECT RATIO 3.9 AND CIRCULAR-ARC AIRFOIL SECTIONS. Robert H. Neely and William Koven. November 13, 1947. 42p. diagrs., photos., 2 tabs. (NACA RM L7E23)

Characteristics of basic wing were poor. The effects on the wing characteristics of extensible round-nose leading-edge flaps located on the outboard 70 percent of the semispan, and of a fuselage with fineness ratio 10.2 located in the low, middle, and high positions were investigated. Tests covered a range of Reynolds numbers from 3.09×10^6 to 9.60×10^6.

NACA RM L7E29

ESTIMATION OF RANGE OF STABILITY DERIVATIVES FOR CURRENT AND FUTURE PILOTLESS AIRCRAFT. Marvin Pitkin and Herman O. Ankenbruck. October 8, 1947. 22p. diagrs., tab. (NACA RM L7E29)

The estimated range of the aerodynamic and mass stability derivatives for airplanes and missiles is given primarily as an aid to designers of "flight tables" and "simulators."

NACA RM L7F04a

LOW-SPEED CHARACTERISTICS IN PITCH OF A 34° SWEPTFORWARD WING WITH CIRCULAR-ARC AIRFOIL SECTIONS. D. William Conner and Patrick A. Cancro. January 9, 1948, 35p. diagrs., photos. (NACA RM L7F04a)

Contains low-speed lift, drag, and pitching-moment characteristics of a 34° sweptforward wing with aspect ratio 3.9 and circular-arc airfoil sections tested with a fuselage and high-lift and stall-control devices. Adding a fuselage to the basic wing reduced the undesirable variations in pitching moment in the high-lift range. Adding full-span, extended, round-nose, leading-edge flaps to the midwing-fuselage combination increased the maximum lift coefficient to 1.30 without seriously decreasing the longitudinal stability. Combinations with half-span split flaps had unfavorable pitching-moment characteristics.

NACA RM L7F13

MEASUREMENTS OF AERODYNAMIC CHARACTERISTICS OF A 35° SWEPTBACK NACA 65-009 AIRFOIL MODEL WITH 1/4-CHORD PLAIN FLAP BY THE NACA WING-FLOW METHOD. Harold I. Johnson. August 5, 1947. 72p. diagrs., photos. (NACA RM L7F13)

As part of a general investigation of the stability and control characteristics of various airfoil-flap combinations in the transonic speed range, measurements were made by the NACA wing-flow method of the lift, pitching-moment, and hinge-moment characteristics of a 35° sweptback NACA 65-009 airfoil of aspect ratio 3.04, with a full-span 1/4-chord unsealed plain flap. The tests covered Mach numbers from 0.55 to 1.10, Reynolds numbers from about 500,000 to 1,300,000, angles of attack from -2° to 15°, and flap deflections from about -20° to 20°.

NACA RM L7F16

LANGLEY FULL-SCALE-TUNNEL INVESTIGATION OF MAXIMUM LIFT AND STABILITY CHARACTERISTICS OF AN AIRPLANE HAVING APPROXIMATELY TRIANGULAR PLAN FORM (DM-1 GLIDER). J. Calvin Lovell and Herbert A. Wilson, Jr. August 5, 1947. 44p. diagrs., photos., tab. (NACA RM L7F16)

This glider had an aspect ratio of 1.8 and 60° sweepback. The investigation consisted of the determination of the separate effects of the following modifications made to the glider on its maximum lift and stability characteristics: (a) installation of sharp leading edges over the inboard semispan of the wing, (b) removal of the vertical fin, (c) sealing of the elevon control-balance slots, (d) installation of redesigned thin vertical surfaces, (e) installation of faired sharp leading edges, and (f) installation of canopy.

NACA RM L7F19

PRELIMINARY INVESTIGATION OF SPOILER LATERAL CONTROL ON A 42° SWEPTBACK WING AT TRANSONIC SPEEDS. Leslie E. Schneiter and Howard L. Ziff. August 12, 1947. 13p. diagrs. (NACA RM L7F19)

This investigation was performed on a double-wedge type semispan wing by the NACA wing-flow method of testing. Above a Mach number of 0.6, the effectiveness of the spoiler in producing rolling moment at an angle of attack of 3° increased as a Mach number of 0.90 was approached. At Mach numbers greater than 0.90, the spoiler effectiveness decreased rapidly until a Mach number of 1.05 was attained, above which point the effectiveness increased slightly as speed was further increased.

NACA RM L7I24

AN ANALYSIS OF DUCTED-AIRFOIL RAM JETS FOR SUPERSONIC AIRCRAFT. Paul R. Hill and A. A. Gammal. July 7, 1948. 43p. diagrs. (NACA RM L7I24)

The effect of sweepback on the external aerodynamics of ducted airfoils with the leading edge ahead of the Mach cone is shown to be small. Possible total pressure recoveries are determined for two-dimensional wedge-type diffuser inlets in order to compute thrust and propulsive coefficients for a wide range of hydrocarbon fuel-air ratios. The possible range and acceleration performances are determined for aircraft with fineness ratio 10, parabolic body-of-revolution fuselages with both ducted wing and ducted tails of various sizes relative to the fuselage size.

NACA RM L7I30

YAW CHARACTERISTICS AND SIDEWASH ANGLES OF A 42° SWEPTBACK CIRCULAR-ARC WING WITH A FUSELAGE AND WITH LEADING-EDGE AND SPLIT FLAPS AT A REYNOLDS NUMBER OF 5,300,000. Reino J. Salmi and James E. Fitzpatrick. December 10, 1947. 38p. diagrs., photos., tab. (NACA RM L7I30)

Contains results of tests of a 42° sweptback wing at a Mach number of 0.11. The dihedral effect of the sharp-edged-airfoil wing became negative at moderate lift coefficients similar to low Reynolds number results of round-nosed airfoil wings. Flap deflection produced positive effective dihedral. The plain wing had neutral directional stability with flaps neutral but was stable with flaps deflected. Air-stream surveys of the sidewash angles of various wing fuselage combinations showed that maximum vertical-tail effectiveness would be obtained on a low-wing combination.

NACA RM L7J03

INVESTIGATION OF PRESSURE DISTRIBUTION OVER AN EXTENDED LEADING-EDGE FLAP ON A 42° SWEPTBACK WING. D. William Conner and Gerald V. Foster. December 19, 1947. 12p. diagrs. (NACA RM L7J03)

Pressure distributions over an extended leading-edge flap, mounted on a 42° sweptback wing and deflected 50°, are presented for several angles of attack. Results indicate that the flap normal-force coefficient increased almost linearly with angle of attack to a maximum value of 3.25. Peak negative pressures built up at the flap leading edge with angle of attack and caused the chordwise location of the flap center of pressure to be moved forward. For the high angle-of-attack range, the center of pressure ranged between 49 and 55 percent of the flap chord.

NACA RM L7J10

PRELIMINARY TESTS TO DETERMINE THE MAXIMUM LIFT OF WINGS AT SUPERSONIC SPEEDS. James J. Gallagher and James N. Mueller. December 11, 1947. 41p. diagrs., photos., 3 tabs. (NACA RM L7J10)

Contains a variety of wing plan forms of random thickness distribution which were tested at Mach numbers of 1.55, 1.90, and 2.32 at angles of attack ranging from zero up through the angle at which maximum lift occurred. In general, at these Mach numbers the value of maximum lift coefficient was approximately 1.05 ± 0.05; it appeared to be independent of plan form and decreased slightly with increasing Mach number. No discontinuities in lift occurred from zero angle of attack through maximum lift, which was attained at approximately 40° angle of attack. Lift-drag ratios at maximum lift were of the order of 1.0.

NACA RM L7K13

WIND-TUNNEL INVESTIGATION OF THE LOW-SPEED STABILITY AND CONTROL CHARACTERISTICS OF A MODEL WITH A SWEPTBACK VEE TAIL AND A SWEPTBACK WING. Edward C. Polhamus. May 25, 1948. 31p. diagrs. (NACA RM L7K13)

Tests were made in the Langley 300-mph 7- by 10-foot tunnel of a complete model with a sweptback vee tail and a sweptback wing to determine its low-speed stability and control characteristics. Tests were also made of the wing alone and of the wing in combination with the fuselage. Comparisons are made with the results of tests of the same tail panel with zero dihedral (horizontal tail) on the same wing-fuselage combination.

NACA RM L8B13

MEASUREMENT THROUGH THE SPEED OF SOUND OF STATIC PRESSURES ON THE REAR OF UNSWEPT AND SWEPTBACK CIRCULAR CYLINDERS AND ON THE REAR AND SIDES OF A WEDGE BY THE NACA WING-FLOW METHOD. Richard H. Sawyer and Fred L. Daum. July 21, 1948. 13p. diagrs., photos. (NACA RM L8B13)

Static-pressure measurements were made through the speed of sound by the NACA wing-flow method at the rear of two unswept circular cylinders of different length-diameter ratio and one 45° sweptback circular cylinder. Additional measurements were made at the rear and sides of a wedge. A Mach number range from about 0.7 to about 1.2 was covered in the tests.

NACA RM L8D23

TESTS OF THE NACA 64_1-012 AND 64_1A012 AIRFOILS AT HIGH SUBSONIC MACH NUMBERS. W. F. Lindsey and Milton D. Humphreys. July 9, 1948. 19p. diagrs., tab. (NACA RM L8D23)

An investigation of NACA 64_1-012 and 64_1A012 airfoils at Mach numbers between 0.35 and 0.89 and at low Reynolds numbers showed the effect of increasing the trailing-edge angle from 9° (NACA 64_1-012) to 14° (NACA 64_1A012).

NACA RM L8H25

STATIC LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A 52° SWEPTBACK WING OF ASPECT RATIO 2.88 AT REYNOLDS NUMBERS FROM 2,000,000 TO 11,000,000. James E. Fitzpatrick and Gerald V. Foster. November 16, 1948. 21p. diagrs., photo. (NACA RM L8H25)

Presents results of test of a 52° sweptback wing with aspect ratio of 2.88, taper ratio 0.625, and NACA 64_1-112 airfoil sections perpendicular to the 0.282-chord line for Reynolds number range of 2,000,000 to 11,000,000. Tests were made with and without half-span split flaps for both the smooth and rough conditions. The tests also included a study of the flow changes at moderate to high lift coefficients.

NACA RM L8H25a

STATIC TESTS OF FOUR TWO-BLADE NACA PROPELLERS DIFFERING IN CAMBER AND SOLIDITY. Robert J. Platt, Jr. December 2, 1948. 23p. diagrs., photo. (NACA RM L8H25a)

Contains static-test data on two-blade propellers of the NACA 4-(3)(08)-03, 4-(5)(08)-03, 4-(10)(08)-03, and 4-(3)(08)-045 designs at blade angles from 0° to 40°. Some earlier data are included which were obtained with the propellers fluttering.

NACA RM L8H30

INVESTIGATION OF THE EFFECT OF SWEEP ON THE FLUTTER OF CANTILEVER WINGS. J. G. Barmby, H. J. Cunningham and I. E. Garrick. November 15, 1948. 70p. diagrs., photo., 7 tabs. (NACA RM L8H30. Now issued as TN 2121; Rept. 1014)

An experimental and analytical investigation of the flutter of uniform, cantilever, sweptback wings is reported. The experiments employed groups of wings swept back by rotating and by shearing. The angle of sweep ranged from 0° to 60° and the Mach numbers extended to approximately 0.9. Comparison with experiment indicates that the analysis developed in the present paper is satisfactory for nearly uniform cantilever wings of moderate length-to-chord ratios.

NACA RM L8I17

A METHOD FOR CALCULATING FLOW FIELDS OF COWLINGS WITH KNOWN SURFACE-PRESSURE DISTRIBUTIONS. Robert W. Boswinkle, Jr. November 22, 1948. 23p. diagrs. (NACA RM L8I17)

Describes a way in which the data of three previous papers may be utilized to compute the incompressible flow fields of cowling-spinner combinations and open-nose inlets at zero incidence. The method consists of regarding the cowling surface as replaced by a ring vortex sheet whose strength at any point is equal to the local tangential velocity. The field of the ring vortex sheet is integrated to give the induced velocities of the body. An approximate method is given for cowlings at angles of attack. A comparison of calculated points with experimental data indicates that the method gives adequate accuracy for propeller design purposes. The application of the Prandtl-Glauert rule for compressible flow is given in detail.

NACA RM L8I24

SURFACE-PRESSURE DISTRIBUTIONS ON A SYSTEMATIC GROUP OF NACA 1-SERIES COWLINGS WITH AND WITHOUT SPINNERS. Robert W. Boswinkle, Jr. and Arvid L. Keith, Jr. November 30, 1948. 188p. diagrs., 3 tabs. (NACA RM L8I24)

Presents the static-pressure distributions on the tops of 79 NACA 1-series cowling-spinner combinations and 9 NACA 1-series open-nose cowlings over wide ranges of inlet-velocity ratio at angles of attack of 0°, 2°, 4°, and 6° for use in calculating the flow fields of such cowlings. This flow field information is useful in the design of propellers. Some effects of changes in the internal lip shape and of propeller operation on the surface pressures on the cowlings are shown.

NACA RM L8J01

INVESTIGATION OF HORN BALANCES ON A 45° SWEPTBACK HORIZONTAL TAIL SURFACE AT HIGH SUBSONIC SPEEDS. Harold S. Johnson and Robert F. Thompson. December 3, 1948. 63p. diagrs., photo., 2 tabs. (NACA RM L8J01)

A wind-tunnel investigation of horn balances on a 45° sweptback, semispan, horizontal tail surface was made to determine the effects of horn size and inboard-edge fairing at a Mach number of 0.30 and to determine the effects of compressibility up to a Mach number of 0.89. Presented are lift, drag, pitching-moment, and hinge-moment data and lift and hinge-moment parameters.

NACA RM L8K19

WIND-TUNNEL INVESTIGATION AT LOW SPEEDS OF VARIOUS PLUG-AILERON AND LIFT-FLAP CONFIGURATIONS ON A 42° SWEPTBACK SEMISPAN WING. Leslie E. Schneiter and James M. Watson. January 26, 1949. 45p. diagrs., photos. (NACA RM L8K19)

Contains results and discussion of a high-lift and lateral-control investigation at low speed on a 42° sweptback semispan-wing model. The lift characteristics of a full-span slotted flap at various deflections and positions of the flap nose, a partial-span slotted flap, and a partial-span Zap flap were determined in addition to a determination of the lateral-control characteristics of a plug-aileron configuration and various modifications thereof, and the characteristics of a partial-span plain aileron in both the flap-retracted and flap-deflected configurations.

NACA RM L8L06

AN INVESTIGATION OF THE CHARACTERISTICS OF THREE NACA 1-SERIES NOSE INLETS AT SUBCRITICAL AND SUPERCRITICAL MACH NUMBERS. Robert E. Pendley and Norman F. Smith. January 13, 1949. 38p. diagrs., photo. (NACA RM L8L06)

Results of measurements of pressure distribution and drag are presented for NACA 1-65-050, NACA 1-50-100, and NACA 1-40-200 nose inlets. Data were obtained at two fineness ratios and at Mach numbers up to 0.925 for a range of inlet-velocity ratio. An appreciable margin was measured between the critical Mach number and the Mach number at which a drag rise occurred. A sharp pressure peak raised at the inlet lip at low inlet-velocity ratios did not affect the Mach number for drag rise.

NACA RM L9A07

LOW-SPEED INVESTIGATION OF AILERON AND SPOILER CHARACTERISTICS OF A WING HAVING 42° SWEEPBACK OF THE LEADING EDGE AND CIRCULAR-ARC AIRFOIL SECTIONS AT REYNOLDS NUMBERS OF APPROXIMATELY 6.0×10^6. Stanley H. Spooner and Robert L. Woods. March 10, 1949. 58p. diagrs., photos. (NACA RM L9A07)

The lateral characteristics of an aileron and several spoiler arrangements on a 42° sweptback wing with symmetrical circular-arc airfoil sections and various high-lift and stall-control devices are shown. Includes aileron normal-force, hinge-moment, and balance-chamber pressure coefficients. The Reynolds number of the tests, which were conducted in the Langley 19-foot pressure tunnel, varied from 5.3×10^6 to 6.9×10^6 which corresponded to a Mach number range of 0.11 to 0.15.

NACA RM L9A18

PRESSURE-DISTRIBUTION MEASUREMENTS OVER AN EXTENSIBLE LEADING-EDGE FLAP ON TWO WINGS HAVING LEADING-EDGE SWEEP OF 42° AND 52°. Reino J. Salmi. March 7, 1949. 36p. diagrs., photos. (NACA RM L9A18)

Contains results of pressure-distribution measurements over a leading-edge flap on two wings having leading-edge sweep of 42° and 52° with NACA 64_1-112 sections. The 42° sweptback wing was of aspect ratio 4.01, taper ratio 0.625, equipped with half-span split flaps and was tested in combination with a circular fuselage at a Reynolds number of 5.12×10^6 and Mach number of 0.11. The 52° sweptback wing was of aspect ratio 2.88, taper ratio 0.625, equipped with half-span split flaps and a fence. The tests were made at a Reynolds number of 4.4×10^6 and Mach number of 0.08, and at various angles of yaw.

NACA RM L9F10

PRELIMINARY AERODYNAMIC INVESTIGATION OF THE EFFECT OF CAMBER ON A 60° DELTA WING WITH ROUND AND BEVELED LEADING EDGES. John M. Riebe and Joseph E. Fikes. August 16, 1949. 46p. diagrs., photos., tab. (NACA RM L9F10)

Contains the results of an investigation in the Langley 300-mph 7- by 10-foot wind tunnel to determine the effect of camber on lift-drag ratio and the longitudinal and lateral stability characteristics on a 60° delta wing at Reynolds numbers of 1.5×10^6 and 3.0×10^6. Angles of attack ranged from 0° to 40°; angles of yaw ranged from -4° to 20°. Camber was produced by full-span leading-edge flaps of round and beveled shapes deflected through a range of 0° to 60°.

NACA RM L9H09

PERFORMANCE CHARACTERISTICS OF TWO 6° AND TWO 12° DIFFUSERS AT HIGH FLOW RATES. William J. Nelson and Eileen G. Popp. October 19, 1949. 26p. diagrs. (NACA RM L9H09)

The aerodynamic characteristics of two circular-inlet and two annular-inlet diffusers of fixed area ratio (1.75) have been determined at inlet Mach numbers from 0.2 to the choked condition. The pressure-loss coefficient and diffuser effectiveness of each of these diffusers is shown to be essentially independent of Reynolds number in the subcritical-flow range; the performance falls off rapidly when sonic velocity is exceeded at any point in the system. Pressure distributions across both the inlet and exit and along the diffuser walls are presented. Inlet-boundary-layer profiles were also measured.

NACA RM L9H23

AN INVESTIGATION OF THE CHARACTERISTICS OF AN UNSWEPT WING OF ASPECT RATIO 4.01 IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL. Ralph P. Bielat and Maurice S. Cahn. November 8, 1949. 32p. diagrs., 2 tabs. (NACA RM L9H23)

An investigation of the characteristics of a wing of aspect ratio 4.01 was conducted at high subsonic Mach numbers in the Langley 8-foot high-speed tunnel. The results of this investigation indicate that the severe changes in aerodynamic characteristics usually associated with wings of average or high aspect ratio were alleviated and were delayed to higher Mach numbers.

NACA RM L9J03

SURVEY OF TWO-DIMENSIONAL DATA ON PITCHING-MOMENT CHANGES NEAR MAXIMUM LIFT CAUSED BY DEFLECTION OF HIGH-LIFT DEVICES. Jerold M. Bidwell and Jones F. Cahill. December 2, 1949. 13p. diagrs., tab. (NACA RM L9J03)

The large pitching-moment increments associated with deflection of certain types of trailing-edge high-lift devices have made it difficult or impossible to obtain trim during landing and take-off. As an aid in the selection of high-lift devices, therefore, a survey has been made of two-dimensional data on the changes in pitching moment resulting from deflection at various types of high-lift devices. The types of high-lift devices investigated include extensible and nonextensible leading-edge and trailing-edge flaps and slats.

NACA RM E6J21

EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF A TURBOJET ENGINE AT ZERO RAM BY MEANS OF TAIL-PIPE BURNING. Bruce T. Lundin, Harry W. Dowman and David S. Gabriel. January 6, 1947. 34p. diagrs., photos., tab. (NACA RM E6J21)

The performance of a turbojet engine equipped with a tailpipe burner designed by the NACA has been investigated at zero ram over a range of rotor speeds and tailpipe-burner fuel flows. The burner consisted essentially of an enlarged tailpipe incorporating fuel-spray nozzles and a flame holder. An adjustable-area exhaust nozzle is installed at the burner discharge.

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL TO UNCLASSIFIED, 1/8/54.

NACA RM A8A20

AN INVESTIGATION OF SUBMERGED AIR INLETS ON A 1/4-SCALE MODEL OF A TYPICAL FIGHTER-TYPE AIRPLANE. Noel K. Delany. June 2, 1948. 47p. diagrs., photos. (NACA RM A8A20)

Results are presented for ramp plan forms with parallel and with diverging walls and show the effect of the duct-entrance location (forward of the wing and over the wing), internal ducting efficiency, and deflectors. The air inlets having the ramps with diverging walls were satisfactory in both locations tested on the fuselage. The submerged air inlets with parallel ramp walls had lower ram pressure recoveries for the normal operating range. The ram pressure-recovery ratios measured at the inlets were higher for the forward location of the inlets than for the aft location.

NACA RM E7H27

INDIRECT METHODS FOR OBTAINING RAM-JET EXHAUST-GAS TEMPERATURE APPLIED TO FUEL-METERING CONTROL. Eugene Perchonok, William H. Sterbentz and Stanley H. Moore. January 14, 1948. 36p. diagrs. (NACA RM E7H27)

Presents development and experimental verification of analytical method that gives two independent means of obtaining total-temperature ratio across a ram jet or turbojet tail-pipe burner without direct measurement of final gas temperature. Proposes several total-temperature-ratio meter designs, which provide simple means of evaluating total-temperature ratio and also provide basis for ram-jet fuel-metering controls using total-temperature ratio as control variable.

NACA RM E8D30

VIBRATION SURVEY OF NACA 24-INCH SUPERSONIC AXIAL-FLOW COMPRESSOR. André J. Meyer, Jr. and Morgan P. Hanson. July 30, 1948. 45p. diagrs., photos. (NACA RM E8D30)

Vibration investigations were made of two blade cascades in wind tunnels and of blades operated in the NACA 24-inch supersonic compressor. The results showed that the blade vibrations were present at all tunnel and compressor air velocities and were influenced primarily by tunnel design, simulated centrifugal loading, surging angle of attack, and possible critical Mach numbers.

NACA RM E50I29a

INTERPRETATION OF BOUNDARY-LAYER PRESSURE-RAKE DATA IN FLOW WITH A DETACHED SHOCK. Roger W. Luidens and Robert T. Madden. December 22, 1950. 14p. diagrs., photos. (NACA RM E50I29a)

A procedure is presented for determining boundary-layer quantities from pressure-rake data, which includes the combined effects of viscous and shock losses. The analysis utilizes schlieren photographs of the shock configuration, the continuity of mass relationship, and the characteristic of the turbulent boundary layer that its outer edge is defined by a rapid change in the slope of the Mach number profile.

NACA RM L7A08

EFFECT OF NUMBER OF FINS ON THE DRAG OF A POINTED BODY OF REVOLUTION AT LOW SUPERSONIC VELOCITIES. N. Mastrocola. April 7, 1947. 10p. diagrs., photos. (NACA RM L7A08)

The interference drag increased with increased number of fins up to a Mach number of 1.35; above this value the effect is reversed. The magnitude of interference effects, for the bluff fin sections used in these tests, is such as to make these effects important in estimating the drag of a multifin tail group. The fin drag was found to be comparatively large and was attributed to the blunt leading edge and square trailing edge of the fin airfoil section.

The test data from flight tests of three- and five-fin bodies up to a Mach number of approximately 1.4 are given.

NACA RM L7B20

COMPARATIVE DRAG MEASUREMENTS AT TRANSONIC SPEEDS OF 6-PERCENT-THICK AIRFOILS OF SYMMETRICAL DOUBLE-WEDGE AND CIRCULAR-ARC SECTIONS FROM TESTS BY THE NACA WING-FLOW METHOD. Norman S. Silsby. April 8, 1947. 10p. diagrs. (NACA RM L7B20)

Both airfoils had a thickness of 6 percent of the chord, were of rectangular plan form, and had an aspect ratio of 4.0. The tests were run at M = 0.65 to 1.10. The results indicated that the principal difference in the drag characteristics of the two airfoils at zero lift is the earlier drag rise of the double-wedge section. Although the double-wedge airfoil had a somewhat higher drag throughout the Mach number range tested, the difference decreased with increasing Mach number after the onset of the drag rise of the circular-arc section, and at M = 1.10 the drag coefficient for the two airfoils was about the same.

NACA RM L7C05

DRAG CHARACTERISTICS OF RECTANGULAR AND SWEPT-BACK NACA 65-009 AIRFOILS HAVING VARIOUS ASPECT RATIOS AS DETERMINED BY FLIGHT TESTS AT SUPERSONIC SPEEDS. Warren A. Tucker and Robert L. Nelson. April 22, 1947. 15p. diagrs., photos. (NACA RM L7C05)

Wings of aspect ratios 3.8 to 5.0 were used at Mach numbers 1.0 to 1.3. The drag coefficient decreased as the sweepback angle increased, the rate of decrease being somewhat greater for the larger aspect ratios. For Mach numbers greater than a value somewhat less than that at which the Mach line lies along the leading edge, the drag coefficient decreased with a decrease in aspect ratio.

NACA RM L7K12

PRESSURE DISTRIBUTION OVER A SHARP-NOSE BODY OF REVOLUTION AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. Edward C. B. Danforth and J. Ford Johnston. March 5, 1948. 25p. diagrs., photos. (NACA RM L7K12)

Contains pressure distributions by the NACA wing-flow method at Mach numbers between 0.70 and 1.05, over a sting-mounted body of revolution of circular-arc profile and fineness ratio 6. The measurements are compared with existing subsonic and supersonic theory where applicable. The manner in which transition occurs from the subsonic to the supersonic type of pressure distribution is shown with particular reference to the accompanying rapid increases in pressure drag.

NACA RM L8F23

A LIMIT PRESSURE COEFFICIENT AND AN ESTIMATION OF LIMIT FORCES ON AIRFOILS AT SUPERSONIC SPEEDS. John P. Mayer. August 23, 1948. 18p. diagrs. (NACA RM L8F23)

The results of an estimation of the limit forces on airfoils at supersonic speeds are presented. Computed values of the forces on two-dimensional wings are in good agreement with three-dimensional wind-tunnel data at high angles of attack where detached shock waves are present. A limit pressure coefficient attainable on an airfoil is given as based on experimental data. The empirical limit pressure coefficient corresponds to about 70 percent of the pressure coefficient for a vacuum.

NACA RM L8H06

PRESSURE DISTRIBUTIONS OVER A WING-FUSELAGE MODEL AT MACH NUMBERS OF 0.4 TO 0.99 AND AT 1.2. Clarence W. Matthews. November 3, 1948. 24p. diagrs. (NACA RM L8H06)

Pressure coefficients and Mach numbers are presented for the flow over a prolate spheroid and an NACA 65-010 wing section in the transonic Mach number range. The values over the prolate spheroid are compared with theoretical values. A study is made of the development of a supersonic flow pattern. Tunnel-wall-constriction effects at Mach numbers near unity are also considered.

NACA RM L8H31a

EFFECT OF STRUT-MOUNTED WING TANKS ON THE DRAG OF NACA RM-2 TEST VEHICLES IN FLIGHT AT TRANSONIC SPEEDS. Sidney R. Alexander. November 18, 1948. 13p. diagrs., photos. (NACA RM L8H31a)

Results of a free-flight investigation near zero lift of an NACA RM-2 drag research model equipped with strut-mounted wing tanks of fineness ratio 7.44 are presented for a Mach number range from about 0.7 to 1.1. The addition of the tanks and struts caused the drag rise to occur at a lower Mach number and produced a drag-coefficient increment of 0.075 at a Mach number of 0.72 which increased to 0.82 (the maximum increment obtained) at a Mach number of 1.06. Estimation indicates that the proximity of the struts and tanks may produce significant trim changes in the Mach number range investigated.

NACA RM L8L07a

FLIGHT INVESTIGATIONS AT LOW SUPERSONIC SPEEDS TO DETERMINE THE EFFECTIVENESS OF CONES AND A WEDGE IN REDUCING THE DRAG OF ROUND-NOSE BODIES AND AIRFOILS. Sidney R. Alexander. March 3, 1949. 15p. diagrs., photos. (NACA RM L8L07a)

It is clearly indicated from results and tests conducted at low supersonic speeds that a small cone placed ahead of a round-nose body can effectively reduce the drag of the basic body. The presence of a small wedge placed ahead of a round-nose airfoil did not appreciably affect the drag of the basic airfoil in the investigated Mach number range of M = 1.05 to 1.225.

NACA RM L9A12

AERODYNAMIC CHARACTERISTICS OF A 6-PERCENT-THICK SYMMETRICAL DOUBLE-WEDGE AIRFOIL AT TRANSONIC SPEEDS FROM TESTS BY THE NACA WING-FLOW METHOD. Lindsay J. Lina. March 4, 1949. 27p. diagrs. (NACA RM L9A12)

Tests were made in the transonic speed range by the NACA wing-flow method to investigate the lift, pitching-moment, and drag characteristics of a 6-percent-thick-chord symmetrical double-wedge airfoil having a rectangular plan form of aspect ratio 4.0. The tests covered a range of Mach numbers from 0.66 to 1.12.

NACA RM L9B17

EXPERIMENTAL DETERMINATION OF THE SUBSONIC PERFORMANCE OF A RAM-JET UNIT CONTAINING THIN-PLATE BURNERS. John R. Henry. June 29, 1949. 54p. diagrs., photos. (NACA RM L9B17)

A ram-jet unit containing a cluster of thin-plate burners in a semicircular combustion chamber was tested in Langley induction aerodynamics laboratory. Data were taken over a fuel-air-ratio range from 0 to 0.049, at combustion-chamber inlet velocities from 40 to 195 feet per second, and at simulated free-stream Mach numbers from 0.20 to 0.55. Combustion efficiencies from 56 to 72 percent were obtained. Combustion-chamber characteristics led to the conclusion that high-thrust-output operation would not be feasible. Thrust-coefficient estimates for supersonic flight are regarded as too low to be practical. Diffuser efficiencies of 99 percent were obtained.

NACA RM L9F02

FLIGHT INVESTIGATION AT HIGH-SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS TO DETERMINE ZERO-LIFT DRAG OF BODIES OF REVOLUTION HAVING FINENESS RATIO OF 6.04 AND VARYING POSITIONS OF MAXIMUM DIAMETER. Ellis R. Katz. August 31, 1949. 17p. diagrs., photo. (NACA RM L9F02)

Flight investigation of rocket-powered models was performed at high-subsonic, transonic, and supersonic speeds to determine the zero-lift drag of fin-stabilized bodies of revolution differing only in position of maximum diameter. The bodies were of 6.04 fineness ratio and had cut-off sterns with equal base area for all models.

NACA RM L9H08

AN EMPIRICAL METHOD FOR ESTIMATING TRAILING-EDGE LOADS AT TRANSONIC SPEEDS. T. H. Skopinski. October 6, 1949. 43p. diagrs., tab. (NACA RM L9H08)

An empirical method for estimating trailing-edge loads and moments in the transonic region is presented. A comparison of the experimental trailing-edge normal-force and bending-moment coefficients obtained for 15 different NACA airfoil sections with those calculated by the proposed empirical method indicated that the method may be used as a guide when specific applicable experimental data are not available at the design stage.

NACA RM L9J11

PRELIMINARY INVESTIGATION OF A VARIABLE MASS-FLOW SUPERSONIC NOSE INLET. Clyde Hayes. December 13, 1949. 15p. diagrs., photos. (NACA RM L9J11)

A method employing an inflatable boot on the central-body surface has been analyzed for varying the mass flow of supersonic inlets having a circular cross section and a central body. The tests made at a Mach number of 2.70 show effects of such a method on the entering flow, mass flow, and pressure recovery.

NACA RM L52E29a

PRELIMINARY INVESTIGATION OF THE EFFECTS OF HEAT TRANSFER ON BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. July 1952. 23p. diagrs., photos., tab. (NACA RM L52E29a)

This paper presents the results of a preliminary investigation of the effects of heat transfer on boundary-layer transition on a parabolic body of revolution (NACA RM-10) at Mach number of 1.61. This paper includes also a study of the effectiveness of cooling on boundary-layer transition with model surface roughened and a comparison of the results obtained in this investigation with other available theoretical and experimental data.

NACA RM L53B25

AN EXTENSION OF THE INVESTIGATION OF THE EFFECTS OF HEAT TRANSFER ON BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. March 1953. 21p. diagrs., photo. (NACA RM L53B25)

This paper covers the extension of a previous investigation of the effects of heat transfer on boundary-layer transition to higher Reynolds numbers, to greater amounts of heating, and to a more extensive study of the effects of surface roughness and wind-tunnel flow disturbances. The tests were made at a Mach number of 1.6 and over a Reynolds number range from 2.5×10^6 to 35×10^6. A comparison is made between the experimental results and theory.

CURRENT NACA REPORTS

NACA TN 3053

A NEW METHOD OF ANALYZING EXTREME-VALUE DATA. Julius Lieblein, National Bureau of Standards. January 1954. 88p. diagrs., 9 tabs. (NACA TN 3053)

A new method based on order statistics is presented for analyzing extreme-value data. The method of application is presented in detail and an actual example is worked out. The techniques described provide a simple means for estimating the necessary parameters, making predictions from the fitted curve, estimating the reliability, and evaluating the efficiency of the method in relation to methods now in use. Comparison with Gumbel's method of moments indicates that, although subject to certain limitations, the method of order statistics offers certain important advantages. The method is discussed in terms of application to gust loads, but it is also applicable to other fields in which extreme values occur.

NACA TN 3062

A FLIGHT INVESTIGATION OF THE PRACTICAL PROBLEMS ASSOCIATED WITH POROUS-LEADING-EDGE SUCTION. Paul A. Hunter and Harold I. Johnson. February 1954. 42p. diagrs., photos., 4 tabs. (NACA TN 3062)

This investigation was concerned with the effect of atmospheric dust and rain on the clogging of the porous leading edge, power requirements, and construction details. In the course of the investigation, the extent of porous area was varied to determine the effect on power requirements and maximum lift coefficients.

NACA TN 3065

PRESENT STATUS OF INFORMATION RELATIVE TO THE PREDICTION OF SHOCK-INDUCED BOUNDARY-LAYER SEPARATION. Roy H. Lange. February 1954. 16p. diagrs. (NACA TN 3065)

The present status of available information relative to the prediction of shock-induced boundary-layer separation is discussed. Experimental results showing the effects of Reynolds number and Mach number on the separation of both laminar and turbulent boundary layers are given and compared with results obtained by available methods for predicting separation. The flow phenomena associated with separation caused by forward-facing steps, wedges, and incident shock waves are discussed. Applications of the flat-plate data to problems of separation on spoilers, diffusers, and scoop inlets are indicated for turbulent boundary layers.

NACA TN 3066

EFFECT OF SURFACE ROUGHNESS OVER THE DOWNSTREAM REGION OF A 23° CONICAL DIFFUSER. Jerome Persh and Bruce M. Bailey. January 1954. 57p. diagrs., photo. (NACA TN 3066)

An experimental investigation was conducted to determine the effect of increasing the extent of surface roughness over the downstream region of a 23° conical diffuser with a 2:1 ratio of exit to inlet area and with a constant-area tailpipe approximately 3-1/2 inlet diameters in length. The inlet-boundary-layer thickness was of the order of 5 percent of the inlet diameter. The airflows used in this investigation cover an inlet Mach number range from about 0.10 to 0.40, corresponding to Reynolds numbers of approximately 1×10^6 to 4×10^6 based on inlet diameter. The surface roughening was accomplished by coating the surface of the diffuser with graded cork particles. Incremental bands of roughness were removed from the upstream end (a 1-inch-wide band being retained near the inlet to stabilize the flow) after each series of pressure measurements was made so that the variation of diffuser performance with percent of diffuser length roughened could be determined.

NACA TN 3068

COMPARISON OF MODEL AND FULL-SCALE SPIN RECOVERIES OBTAINED BY USE OF ROCKETS. Sanger M. Burk, Jr. and Frederick M. Healy. February 1954. 63p. diagrs., photos., 5 tabs. (NACA TN 3068)

An investigation of a 1/19-scale model of an unswept-wing trainer airplane was conducted in the Langley 20-foot free-spinning tunnel to determine the rocket spin-recovery characteristics of the model for comparison with available full-scale-airplane results. A rocket was attached to each wing tip to fire in a direction to apply an antispin yawing moment about the Z body axis. The rockets were fired individually and in combination.

NACA TN 3069

INCOMPRESSIBLE FLOW PAST A SINUSOIDAL WALL OF FINITE AMPLITUDE. Carl Kaplan. February 1954. 26p. diagrs., 2 tabs. (NACA TN 3069)

Plane incompressible flow past an infinitely long sinusoidal wall of any amplitude is considered in

the present paper. It was found that this problem could not be treated in the physical plane but had to be transferred to the plane of velocity potential and stream function. In this plane, the problem was not only successfully treated by the small disturbance iteration method but, moreover, its solution was rigorously expressed in the form of a nonlinear integral equation.

NACA TN 3095

THE AMES 10- BY 14-INCH SUPERSONIC WIND TUNNEL. A. J. Eggers, Jr. and George J. Nothwang. January 1954. 43p. diagrs., photos., tab. (NACA TN 3095)

The Ames 10- by 14-inch supersonic wind tunnel is described and pertinent features of the design and operation of the facility are included. The wind tunnel is capable of continuous operation at Mach numbers from 2.7 to 6.3 and Reynolds numbers from 1 million to 11 million per foot. Data on the characteristics of flow in the test section, including pressure and stream-angle distributions, are presented.

NACA TN 3098

DENSITY PROFILES OF SUBSONIC BOUNDARY LAYERS ON A FLAT PLATE DETERMINED BY X-RAY AND PRESSURE MEASUREMENTS. Ruth N. Weltmann and Perry W. Kuhns. February 1954. 30p. diagrs., photos. (NACA TN 3098)

Laminar, transitional, and turbulent boundary layers were investigated in a subsonic wind tunnel at Mach numbers of 0.55 and 0.78 at various Reynolds numbers and stations along a flat plate. Comparisons are made of the density profiles obtained with a total-pressure probe of small frontal opening and by means of an X-ray absorption method and, in a few cases, by using interferometer data. The limitations of the probe and X-ray methods are discussed. The decrease in mass flow in the tunnel due to the insertion of the pressure probe was found to affect the pressure measurements in the boundary layer. A mass-flow correction for the pressure data is suggested. The maximum difference between the mass-flow corrected pressure profiles and the radiation measurements was 0.8 percent in density ratio. No change in boundary-layer type from transitional to turbulent or from laminar to transitional was observed when the probe was inserted into the boundary layer.

NACA TN 3101

STUDY OF THREE-DIMENSIONAL INTERNAL FLOW DISTRIBUTION BASED ON MEASUREMENTS IN A 48-INCH RADIAL-INLET CENTRIFUGAL IMPELLER. Joseph T. Hamrick, John Mizisin and Donald J. Michel. February 1954. 64p. diagrs., photos. (NACA TN 3101)

A study of the loss and velocity distribution in a radial flow impeller was made. It is indicated that secondary flows within the boundary layer and leakage through the blade-to-shroud clearance space result in a concentration of low-energy air at approximately 80 percent of the passage width from the pressure face at the shroud. Comparison of the data from internal measurements made for the impeller of this investigation with hot-wire anemometer studies made at the outlet of a similar impeller indicates that much can be learned about the internal flow picture with hot-wire surveys alone.

NACA TN 3115

ANALYSIS OF SWEPTBACK WINGS ON CAL-TECH ANALOG COMPUTER. Richard H. MacNeal and Stanley U. Benscoter, California Institute of Technology. January 1954. 80p. diagrs., 5 tabs. (NACA TN 3115)

Using the Cal-Tech analog computer, structural analyses have been made of two 45° swept wings of aspect ratio 3. One of these has a constant depth and the other has a constant biconvex cross section in planes parallel to the airstream. The wings extend through the fuselage and are rigidly supported along two lines at the faces of the fuselage. Deflections and all internal forces have been calculated for concentrated static loads. Vibration modes are also presented. The effects of neglecting shearing strains in the ribs and spars and also of assuming the ribs to be rigid have been investigated by modifying the electric circuits to correspond to these simplifications.

NACA TN 3117

LUBRICANTS OF REDUCED FLAMMABILITY. Charles E. Frank, Donald E. Swarts and Kenneth T. Mecklenborg, University of Cincinnati. January 1954. 24p. diagrs., tab. (NACA TN 3117)

Determination of the change in spontaneous ignition temperature with composition for blends of hydrogenated polyisobutylene with typical ester, hydrocarbon, and polyether lubricants has shown that 40 percent hydrogenated polyisobutylene by volume raises the ignition temperature of these lubricants by 60° to 80° C. Preliminary stability tests indicated that the hydrogenated polyisobutylenes possess reasonable thermal stability, suffering a weight loss of about 3 percent after 10 hours at 195° C in an inert atmosphere. Introduction of oxygen accelerates this decomposition rate, but addition of phenyl-beta-naphthylamine reduced the loss to 1 or 2 percent. A practical method for synthesizing polyisobutylene largely in the lubricant molecular weight range has been developed.

NACA TN 3123

EFFECT OF VARIOUS ARRANGEMENTS OF TRIANGULAR LEDGES ON THE PERFORMANCE OF A 23° CONICAL DIFFUSER AT SUBSONIC MACH NUMBERS. Jerome Persh and Bruce M. Bailey. January 1954. 36p. diagrs. (NACA TN 3123)

An experimental investigation was conducted to determine the effect of rough and smooth triangular ledges, approximately one-tenth of the inlet boundary layer thickness in height, on the performance of a 23° conical diffuser with a 2:1 ratio of exit to inlet

area and with a constant-area tailpipe about 3-1/2 inlet diameters in length. The inlet boundary-layer thickness was of the order of 5 percent of the inlet diameter. The airflows used in this investigation covered an inlet Mach number range from about 0.10 to 0.40, corresponding to Reynolds numbers from approximately 1×10^6 to 4×10^6 based on inlet diameter. The rough ledges consisted of graded cork particles and the smooth ledges of balsa-wood strips of triangular cross section. The results of this investigation showed that, although the flow in the diffuser without ledges was very unstable, the presence of a roughness strip near the inlet, with or without additional ledges, assured stable flow. For the configurations investigated, the static-pressure recovery and total-pressure-loss coefficient were either unaffected or slightly impaired by the installation of ledges.

NACA TN 3125

A SIMPLE MECHANICAL ANALOGUE FOR STUDYING THE DYNAMIC STABILITY OF AIRCRAFT HAVING NONLINEAR MOMENT CHARACTERISTICS. Thomas N. Canning. February 1954. 18p. diagrs. (NACA TN 3125)

The analogy between a ball rolling on a suitably contoured surface and a pitching and yawing missile in free flight is developed. The analogue is checked experimentally for the case of linear moment characteristics. Several nonlinear cases are also treated experimentally. Results of ballistic-range firings are also included.

NACA TN 3134

A METHOD FOR ESTIMATING VARIATIONS IN THE ROOTS OF THE LATERAL-STABILITY QUARTIC DUE TO CHANGES IN MASS AND AERODYNAMIC PARAMETERS OF AN AIRPLANE. Ordway B. Gates, Jr. and C. H. Woodling. January 1954. 66p. diagrs., 4 tabs. (NACA TN 3134)

Expressions are presented from which can be calculated the rates of change of the roots of the lateral-stability quartic with respect to the mass and aerodynamic parameters of an airplane. Results obtained from these expressions are compared with the results of exact calculations. The expressions are shown to have a definite relationship to the amplitude coefficients of the lateral modes of motion subsequent to input moments or forces.

NACA TN 3135

INVESTIGATION OF MUTUAL INTERFERENCE EFFECTS OF SEVERAL VERTICAL-TAIL–FUSELAGE CONFIGURATIONS IN SIDESLIP. William H. Michael, Jr. January 1954. 35p. diagrs., photos., 3 tabs. (NACA TN 3135)

This report presents results of sideslip tests made on three circular-arc fuselages and nine unswept vertical tails to determine the mutual interference effects between fuselages and vertical tails. The analysis shows the primary factors affecting the magnitude of the interference effects and the relative magnitudes of the induced loadings on the fuselage and on the vertical tail. Some observations concerning the distribution of the induced loadings are made. Some theoretical calculations of the interference effect of a body on adjacent lifting surfaces are included and compared with the experimental results.

NACA TN 3140

USE OF AERODYNAMIC HEATING TO PROVIDE THRUST BY VAPORIZATION OF SURFACE COOLANTS. W. E. Moeckel. February 1954. 37p. diagrs. (NACA TN 3140)

The thrust and specific impulse obtainable by use of aerodynamic heating to vaporize aircraft surface coolants are determined as a function of Mach number for a variety of possible coolants. Use of hydrogen vaporization as an independent propulsion system yields specific impulses comparable with those of current rocket propellants at very high Mach numbers. For use as an auxiliary power source, coolant vaporization can produce specific impulses comparable with those of current rocket propellants at all Mach numbers.

NACA TN 3158

A SUBSTITUTE-STRINGER APPROACH FOR INCLUDING SHEAR-LAG EFFECTS IN BOX-BEAM VIBRATIONS. William W. Davenport and Edwin T. Kruszewski. January 1954. 23p. diagrs., tab. (NACA TN 3158)

The use of the substitute-stringer approach for including shear-lag in the calculation of transverse modes and frequencies of box beams is discussed. Various thin-walled hollow rectangular beams of uniform wall thickness are idealized by means of the substitute-stringer approach and the resulting frequencies of the idealized structures are compared with those of the original beams. The results indicate how the substitute-stringer idealization could be made in order to yield accurate representation of the shear-lag effect in dynamic analysis.

NACA TN 3159

FLIGHT INVESTIGATION AT LARGE ANGLES OF ATTACK OF THE STATIC-PRESSURE ERRORS OF A SERVICE PITOT-STATIC TUBE HAVING A MODIFIED ORIFICE CONFIGURATION. William Gracey and Elwood F. Scheithauer. February 1954. 25p. diagrs., photos. (NACA TN 3159)

The static-pressure errors of two essentially similar service pitot-static tubes and of three modified orifice arrangements on one of these tubes have been determined from flight tests over a range of angle of attack α of -15° to 45°, at Mach numbers from 0.20 to 0.68 and at Reynolds numbers from 0.9×10^5 to 2.7×10^5 (where Reynolds number is based on local velocity and the diameter of the tube). The tests showed that for Mach numbers from 0.20 to 0.68 and Reynolds numbers from 0.9×10^5 to 1.4×10^5, the static-pressure error will remain within 2 percent of the impact pressure q_c for $\alpha = -10^\circ$ to 30°. Because of pressure fluctuations

and rapidly increasing errors at $\alpha > 30^{\circ}$, the usefulness of the tube is limited to $\alpha < 30^{\circ}$.

NACA RM E53J08

CORRELATION OF ISOTHERMAL CONTOURS FORMED BY PENETRATION OF JET OF LIQUID AMMONIA DIRECTED NORMAL TO AN AIR STREAM. David B. Fenn. February 1954. 38p. diagrs., tab. (NACA RM E53J08)

An investigation was conducted to correlate the isothermal contour lines formed downstream of a single jet of liquid ammonia directed normal to an air stream. Criteria are presented to facilitate the design of jet-engine thrust-augmentation systems utilizing the injection of liquid ammonia to cool the air at the compressor inlet. From the correlation presented, it is possible to construct an isothermal contour map for a single orifice operating within the following range of conditions: air velocity, 112 to 329 feet per second; air density, 0.024 to 0.070 pound per cubic foot; air temperature, 534° to 770° R; ammonia jet velocity, 63 to 244 feet per second; ammonia temperature, 433° to 470° R; mixing distance, 4 to 24 inches; orifice diameter, 0.018 to 0.053 inch. It was verified that the construction of the isothermal contours formed by a multiorifice injection system may be determined by simply adding the temperature drops of the overlapping single-orifice contour maps determined from the correlation.

NACA RM E53K30

FLAME QUENCHING BY A VARIABLE-WIDTH RECTANGULAR-SLOT BURNER AS A FUNCTION OF PRESSURE FOR VARIOUS PROPANE-OXYGEN-NITROGEN MIXTURES. Abraham L. Berlad. January 1954. 42p. diagrs., 3 tabs. (NACA RM E53K30)

Flame quenching by a variable-width rectangular-slot burner as a function of pressure for various propane-oxygen-nitrogen mixtures was investigated. It was found that for cold gas temperatures of 27° C, pressures of 0.1 to 1.0 atmosphere, and volumetric oxygen fractions of the oxidant of 0.17, 0.21, 0.30, 0.50, and 0.70, the relation between pressure p and quenching distance d is approximately given by $d \propto p^{-r}$ with $r = 1$, for equivalence ratios approximately equal to one. The quenching equation of Simon and Belles was tested. For equivalence ratios less than or equal to unity, this equation may be used, together with one empirical constant, to predict the observed quenching distance within 4.2 percent. The equation in its present form does not appear to be suitable for values of the equivalence ratio greater than unity. A quantitative theoretical investigation has also been made of the error implicit in the assumption that flame quenching by plane parallel plates of infinite extent is equivalent to that of a rectangular burner. A curve is presented which relates the magnitude of this error to the length-to-width ratio of the rectangular burner.

NACA RM E53L01

EXPLOSION AND COMBUSTION PROPERTIES OF ALKYLSILANES. I - TEMPERATURE-COMPOSITION LIMITS OF EXPLOSION FOR METHYL-, DIMETHYL-, TRIMETHYL-, TETRAMETHYL-, AND VINYLSILANE AT ATMOSPHERIC PRESSURE. Rose L. Schalla and Glen E. McDonald. February 1954. 11p. diagrs. (NACA RM E53L01)

The explosion limits of five alkylsilanes were determined as a function of temperature and composition at a pressure of 1 atmosphere. Over a fuel concentration range of 2 to 10 percent, the lowest temperatures ($^{\circ}$C) below which explosion did not occur for the five fuels studied were: tetramethylsilane $(CH_3)_4Si$, 450°; trimethylsilane $(CH_3)_3SiH$, 310°; dimethylsilane $(CH_3)_2SiH_2$, 220°; methylsilane CH_3SiH_3, 130°; and vinylsilane $H_2C{=}CH\text{-}SiH_3$, 90°. Explosion limits for hydrocarbons analogous to these silanes fall in a temperature range of 500° to 600° C. Since the explosion temperatures of the alkylsilanes are lower than those of the hydrocarbons and since they decrease as hydrogen atoms are substituted for methyl groups, it was concluded that the Si-H bond is more readily susceptible to oxidation than the C-H bond.

NACA RM E53L08

EFFECT OF WATER ON CARBON MONOXIDE - OXYGEN FLAME VELOCITY. Glen E. McDonald. February 1954. 15p. diagrs., 2 tabs. (NACA RM E53L08)

The flame velocities were measured of 20 percent oxygen and 80 percent carbon monoxide mixtures containing either light water or heavy water. The flame velocity increased from 34.5 centimeters per second with no added water to about 104 centimeters per second for a 1.8 percent addition of light water and to 84 centimeters per second for an equal addition of heavy water. The addition of light water caused greater increases in flame velocity with equilibrium hydrogen-atom concentration than would be predicted by the Tanford and Pease square-root relation. The ratio of the flame velocity of a mixture containing light water to that of a mixture containing heavy water was found to be 1.4. This value is the same as the ratio of the reaction rate of hydrogen and oxygen to that of deuterium and oxygen. A ratio of reaction rates of 1.4 would also be required for the square-root law to give the observed ratio of flame-velocity changes.

NACA RM E53L14

VAPOR PRESSURES AND CALCULATED HEATS OF VAPORIZATION OF CONCENTRATED NITRIC ACID SOLUTIONS IN THE COMPOSITION RANGE 71 TO 89 PERCENT NITRIC ACID, 7 TO 20 PERCENT NITROGEN DIOXIDE, 1 TO 10 PERCENT WATER, AND IN THE TEMPERATURE RANGE 10° TO 60° C. A. B. McKeown and Frank E. Belles. February 1954. 20p. diagrs., 2 tabs. (NACA RM E53L14)

Total vapor pressures were measured for 16 acid mixtures of the ternary system nitric acid, nitrogen dioxide, and water within the temperature range 10° to 60° C and within the composition range 71 to 89 weight percent nitric acid, 7 to 20 weight percent nitrogen dioxide, and 1 to 10 weight percent water. Heats of vaporization were calculated from the vapor pressure measurements for each sample for the temperatures, 25°, 40°, and 60° C. The ullage of the apparatus used for the measurements was 0.46. Ternary diagrams showing isobars as a function of composition of the system were constructed from experimental and interpolated data for the temperatures 25°, 40°, 45°, and 60° C and are presented herein.

NACA TM 1356

EXPERIMENTAL DETERMINATION OF LOCAL AND MEAN COEFFICIENTS OF HEAT TRANSFER FOR TURBULENT FLOW IN PIPES. (Eksperimental'noe Opredelenie Lokal'nykh i Srednikh Koeffitsientov Teplootdachi Pri Turbulentnom Techenii Zhidkosti v Trubakh). I. T. Aladyev. February 1954. 18p. diagrs., 3 tabs. (NACA TM 1356. Trans. from Izvestiya Akademii Nauk SSSR, Otdelenie Tekhnicheskikh Nauk, no. 11, 1951, p. 1669-1681).

Heat-transfer coefficients were determined for the flow of water through a heated pipe. The local heat-transfer coefficient was found to decrease along the length of the pipe up to a distance of about 40 diameters from the entrance. Equations are given for the local and mean heat-transfer coefficients as functions of the Reynolds number, Prandtl number, and length of the pipe in diameters.

THE DETERMINATION OF TURBULENT SKIN FRICTION BY MEANS OF PITOT TUBES. J. H. Preston. March 31, 1953. 31p. diagrs. (ARC 15,758; FM 1883)

A simple method of determining local turbulent skin friction has been developed which utilizes a round pitot tube resting on the surface. Assuming the existence of a region near the surface in which conditions are functions only of the skin friction, the relevant physical constants of the fluid and a suitable length, a universal nondimensional relation is obtained for the difference between the total pressure recorded by the tube and the static pressure at the wall, in terms of the skin friction. This relation is independent of the pressure gradient and surface condition.

THE CHEMISTRY OF SOME COMPLEX ZINC AND CADMIUM CHROME PIGMENTS. H. G. Cole and L. F. Le Brocq. September 1953. 35p. diagrs., photos., 8 tabs. (RAE Met. 75)

By means of pH curves obtained during the progressive addition of alkali to the dichromates of zinc and cadmium, conditions have been found for the formation of double alkali basic chromates of zinc and cadmium with sodium, potassium, and ammonium, and for the decomposition of these compounds by further action of alkali to basic zinc and cadmium chromates. The identity of each compound has been characterized by equation of formation, composition, X-ray diffraction pattern, and solubility. Many of these compounds are of commercial importance as paint pigments.

THE INFLUENCE OF SUB-STRUCTURE ON THE SLIP OBSERVED IN PURE ALUMINIUM AND SOME ALUMINIUM ALLOYS. P. J. E. Forsyth and C. A. Stubbington. October 1953. 14p. diagrs., photos. (RAE Met. 76)

Observations have been made on the modifying effects of substructure on subsequent fatigue deformation both at room and subzero temperatures. Substructures produced by cold rolling altered completely the appearance of the deformation that occurred under subsequent fatigue stresses. A self-annealing process occurred in cold-rolled pure aluminum when subjected to cyclic stresses. It is concluded that fatigue stresses by virtue of their cyclic nature aid the polygonization process in pure aluminum and in certain aluminum alloys and may produce very sharply defined boundaries by a process of crystallite growth.

A METHOD OF PRODUCING HARD SURFACES ON ALUMINIUM AND ITS ALLOYS BY ANODIC OXIDATION. E. G. Savage and E. G. F. Sampson. August 1953. 12p. diagrs., 3 tabs. (RAE Tech. Note Met. 173)

The potential value of relatively thick and hard oxide coatings on aluminum and aluminum alloys led to experiments to determine the conditions under which such coatings, 0.001 inch or more thick, could be produced. It was found that aluminum and a number of aluminum alloys could be successfully treated under one set of conditions in a cooled sulphuric acid electrolyte. Film thickness and abrasion tests were made on the anodised samples and an anodised shaft was run in a steel bearing with promising results. There should be many uses for hard anodised parts, particularly where lightness and wear-resistance are important and where point or line loading or high resistance to fatigue are not required. It is proposed to make a short series of Wöhler-type fatigue tests on hard-anodised material to specification D.T.D.364.

FATIGUE TESTS ON SPECIMENS FROM ALUMINIUM ALLOY D.T.D.683 'Z' SECTION EXTRUSIONS. M. S. Binning and J. T. Ballett. September 1953. 17p. diagrs., 3 tabs. (RAE Tech. Note Met. 179)

Fatigue tests have been made on extruded 'Z' section stringers in high strength aluminum alloy D.T.D.683, to discover if a surface effect detrimental to fatigue strength is present, similar to that found in extruded stringers of aluminum alloy to D.T.D.364. Tests were made in fluctuating tension in high fatigue machines, to determine the effect of surface finish and stress raisers. It has been confirmed that a surface effect is present with D.T.D.683 extrusions. Polishing the extruded surface resulting in an increase of 30 percent in fatigue strength, bringing the fatigue/tensile strength ratio to the same order as that for polished bar to the same specification. When a stress raiser in the form of a hole is present, polishing has little effect but radiusing the edges of the hole increases the fatigue strength by 30 percent.

THE EFFECT OF HEAT AND MOISTURE ON THE TENSILE STRENGTH OF SURFACE-TREATED GLASS FIBRES. R. B. King and E. W. Russell. September 1953. 10p. 4 tabs. (RAE Tech. Note Chem. 1203)

The tensile strength after heat treatment of single high and low alkali glass fibers was examined. The influence of surface agents in reducing the attack of moisture on the glass was also studied. Permanent weakening was sustained with temperatures above 250° C. Of the surface finishes investigated, vinyl trichlorosilane was found to be the most effective. Most of the other treatments showed little or no improvement over control values.

AN ELECTRONIC TRIP TO PREVENT OVERSPEEDING OF A TURBO-ALTERNATOR. D. S. Dean. November 1953. 8p. diagrs. (RAE Tech. Note RPD 91)

A circuit is described which will cut off the fuel supply to a turbine driven alternator when the output of the alternator reaches a predetermined frequency, and thus prevent damage to the unit due to overspeeding. The circuit also incorporates a manual emergency stop which may be operated at any turbine speed. The particular unit described has been designed to operate at any frequency between 2350 and 3000 cycles/second depending upon the setting chosen before the run. It will operate at the same frequency with any input between 2 and 150 volts and is unaffected by the harmonic content of the input signal. The setting is stable to within ±10 cycles/second over a period of weeks.

TRANSIENT TEMPERATURE DISTRIBUTION IN AN INFINITE FLAT PLATE WITH RADIAL HEAT FLOW. S. W. Green. October 1953. 24p. diagrs. (RAE Tech. Note RPD 92)

The temperature distribution in an infinite flat plate originally at uniform temperature has been calculated for prescribed rates of heat transfer across the boundary of a circular hole in the plate. Heat transfer with constant heat-transfer coefficient from a source at constant temperature has been assumed, and the calculations have been made for a range of values of the heat-transfer coefficient.

OUTLINED GENERAL TREATMENT OF THE CALCULATION OF WAVE EFFECTS DUE TO SMALL DISTURBANCES OF STEADY STABILISED BURNING. PART II. P. W. H. Howe. July 1953. 39p. diagrs., 2 tabs. (NGTE R. 135)

The reaction of a region of steady burning to small disturbances (for example, in the fuel supply) is considered. Equations are given for a law of burning such that the rate of change of entropy of a gas particle is proportional to the fuel concentration. It is established that there is a fairly close connection between the pressure pulses produced up to a certain time and extra energy released up to that time. If increased turbulence contributes to the extra heat, release "humped" pressure pulse profiles are obtained.

Marine Aircraft Experimental Establishment (Gt. Brit.) SOME NOTES ON THE CALCULATION OF PRESSURE PICK-UP SENSITIVITY AND THE CONDITIONS FOR MAXIMUM SENSITIVITY. J. K. Friswell. November 1953. 36p. diagrs. (MAEE F/Res/235)

A theoretical analysis is made of the sensitivity of a pressure pickup of the strain-gaged cantilever type and of the conditions for maximum sensitivity. Two different configurations are treated and the effect of tension in the diaphragm is also considered. An account is given of experiments carried out in order to verify the analysis and to observe the behavior outside the range of validity of the theory. Suggestions are made for practical pickup design based on both theory and experiment.

CORROSION OF COMMERCIAL MAGNESIUM ALLOYS. Fred M. Reinhart. May 26, 1953. 25p. photos., 4 tabs. (National Bureau of Standards. Rept. 2519)

An investigation was conducted to determine the relative susceptibilities of all the commercially available magnesium alloys with different surface treatments, both painted and unpainted, to corrosion in marine atmosphere and tidewater environments. The surface coatings on all of the magnesium alloys failed within 24 months after exposure in the marine atmosphere. Paint afforded protection to the majority of the alloys for 12 months in the tidewater. The surface coatings served as good bases for paint for at least 24 months of exposure in the marine atmosphere.

CURRENT NACA REPORTS

NACA Rept. 1123

A STUDY OF INVISCID FLOW ABOUT AIRFOILS AT HIGH SUPERSONIC SPEEDS. A. J. Eggers, Jr., Clarence A. Syvertson and Samuel Kraus. 1953. ii, 27p. diagrs., 6 tabs. (NACA Rept. 1123. Formerly TN 2646; TN 2729)

Steady flow about curved airfoils is investigated analytically, first assuming air behaves as an ideal gas, and then assuming it behaves as a thermally perfect, calorically imperfect gas. Conclusions are drawn from the study.

NACA TN 3063

EFFECTS OF WING POSITION AND FUSELAGE SIZE ON THE LOW-SPEED STATIC AND ROLLING STABILITY CHARACTERISTICS OF A DELTA WING MODEL. Alex Goodman and David F. Thomas, Jr. February 1954. 66p. diagrs., photos., 3 tabs. (NACA TN 3063)

Results are presented of an investigation made to determine the effects of wing position and fuselage size on the low-speed static and rolling stability characteristics of models having a triangular wing and vertical tail surfaces. Interference increments between the various components are evaluated, and the variation of the vertical-tail lift-curve slopes and the efficiency factors with angle of attack as affected by wing position and body size are presented. Tuft-grid pictures of the flow at the vertical tail as affected by wing-fuselage interference are also presented.

NACA TN 3106

AN EVALUATION OF THE SOAP-BUBBLE METHOD FOR BURNING VELOCITY MEASUREMENTS USING ETHYLENE-OXYGEN-NITROGEN AND METHANE-OXYGEN-NITROGEN MIXTURES. Dorothy M. Simon and Edgar L. Wong. February 1954. 30p. diagrs., photos., 5 tabs. (NACA TN 3106)

A nonaqueous soap-bubble method was used to measure the burning velocities of some ethylene-oxygen-nitrogen and methane-oxygen-nitrogen mixtures. Burning velocity calculations were based on high-speed schlieren motion-picture records of the flame growth and a theoretical expansion ratio. An upper limit in the spatial velocity in the range 2500 to 3500 centimeters per second due to the appearance of rough flames was found for the soap-bubble method. Soap-bubble burning velocity measurements were compared with measurements by other methods.

NACA RM 54A04

EFFECTS OF MOLECULAR WEIGHT ON CRAZING AND TENSILE PROPERTIES OF POLYMETHYL METHACRYLATE. I. Wolock, M. A. Sherman and B. M. Axilrod, National Bureau of Standards. February 1954. 11p. diagrs., tab. (NACA RM 54A04)

Tensile and crazing properties are reported for five cast polymethyl-methacrylate sheets in which the molecular weight of the resin was 90,000, 120,000, 200,000, 490,000, and 3,160,000, respectively. Both stress and stress-solvent crazing tests were conducted. The tensile strength and ultimate elongation were found to increase rapidly with increasing molecular weight at the lower molecular weights and to level off at molecular weights of approximately 200,000 and 500,000, respectively. There was no change in the modulus of elasticity over the range studied. The specimens with lowest molecular weight broke at low strains without crazing. The stress and strain at which crazing occurred increased with increasing molecular weights.

KINETIC TEMPERATURE OF WET SURFACES. A METHOD OF CALCULATING THE AMOUNT OF ALCOHOL REQUIRED TO PREVENT ICE, AND THE DERIVATION OF THE PSYCHROMETRIC EQUATION. J. K. Hardy. 1953. 13p. 2 tabs. (ARC R & M 2830. Formerly NACA WR A-8; NACA ARR 5G13)

A method is given for calculating the temperature of a surface wetted either by a pure liquid, such as water, or by a mixture, such as alcohol and water. The method is applied to the problem of protecting, by alcohol, propellers and the induction system of the engine against ice. The minimum quantity of alcohol required is calculated for a number of arbitrarily chosen conditions. The effect of evaporation of alcohol is shown by repeating the calculations for a nonvolatile fluid. The method can be applied to other problems in evaporation, for instance, to the evaporation of fuel in the induction system of the engine. The psychrometric equation, used in wet-bulb hygrometry, is deduced in its general form. The effect of kinetic heating is included in this equation.

OBSERVATIONS ON A THIN CAMBERED AEROFOIL BEYOND THE CRITICAL MACH NUMBER. E. W. E. Rogers. (Read before VIIth International Congress of Applied Mechanics, September 1948) 1953. 16p. diagrs., photos. (ARC R & M 2432. Formerly ARC 13,238; Perf. 685; FM 1455)

In the course of surface pressure measurements and wake traverses on an airfoil section of 10 percent thickness/chord ratio, tested at high subsonic speeds in the 20- by 8-inch (50.8 x 20.3 cm) high-speed wind tunnel of the National Physical Laboratory, it was discovered that at a particular incidence (3.7^{o}) an extensive region of supersonic velocity (M = 1.15) existed without the formation of a well-defined shock wave or a rise of drag. The drag coefficient, in fact, decreased markedly as the Mach number was raised from a low value, and this was accompanied by a rearward movement on the upper surface of the position of boundary-layer transition corresponding to a favorable change of the surface pressure gradient. The transition positions measured with the "china-clay" method are compared with those estimated from the observed drag coefficients. Direct-shadow photographs illustrate the development of the shock-wave pattern.

Aeronautical Research Council (Gt. Brit.)
LOW-SPEED MEASUREMENTS OF THE PRESSURE DISTRIBUTION AT THE SURFACE OF A SWEPT-BACK WING. V. M. Falkner and Doris E. Lehrian. 1953. 36p. diagrs., photo., 27 tabs. (ARC R & M 2741. Formerly ARC 12,647; Perf. 588; S & C 2335)

Measurements were made at selected stations on a sweptback wing with and without body. The wing has 45° sweepback, aspect ratio of 3, and constant chord. The section was chosen to be suitable for work at low Reynolds number. This is the first part of a program on a sweptback wing to provide methods of calculating the pressure at the surface, as well as the general properties of wings. This report covers what is thought to be one of the worst types of discontinuity likely to require investigation (excluding deflected flaps); that is, sudden changes in direction of both leading and trailing edges of the wing.

Aeronautical Research Council (Gt. Brit.)
THE INITIAL BUCKLING OF A LONG AND SLIGHTLY BOWED PANEL UNDER COMBINED SHEAR AND NORMAL PRESSURE. E. H. Brown and H. G. Hopkins. 1953. 19p. diagrs., 4 tabs. (ARC R & M 2766; ARC 12,605. Formerly RAE Structures 42)

Recent American experimental work has suggested that the resistance to buckling of wing skin panels under compression or shear loads is improved by aerodynamic suction. A complete theoretical analysis of this problem is very difficult, because, compression load necessarily involves the consideration of post-buckling behavior. An approach is made in this report by considering the restricted problem of the initial buckling of a long, thin, and slightly bowed panel under combined shear and normal pressure. The theoretical values of the initial shear buckling stress which agree well with American experimental values, increase with both pressure and curvature; the wave length of the buckles also increases with pressure, but decreases with curvature. The difference between the buckling stresses for simply supported and clamped edges is considerable for a flat panel under shear alone but decreases rapidly with curvature and pressure, thus making the indeterminacy of practical edge conditions of less importance.

TWO-DIMENSIONAL AEROFOIL DESIGN IN COMPRESSIBLE FLOW. L. C. Woods. 1953. 19p. diagrs., 3 tabs. (ARC R & M 2731. Formerly ARC 12,922; FM 1412)

This paper deals with the following two-dimensional problem: "The design of an airfoil to give a specified velocity against chord curve at a given free-stream Mach number." A "relaxation" method is adopted, based on the differential equations for incompressible and compressible flow. An essential feature of the method is that the calculations are carried out in the (ϕ,ψ) or w-plane in which the airfoil is represented by a slit along $\psi = 0$. The square mesh in this plane is formed by the streamlines (ψ = constant), and equipotentials (ϕ = constant) for incompressible flow about the airfoil. The method is developed for a symmetrical airfoil at zero incidence, but the modifications necessary for the more general case are indicated. A worked example is given, from which some idea of the accuracy of the method can be gained. The compressible velocity distribution about a known airfoil was taken as the initial data. This airfoil was actually 12 percent thick at 30 percent of the chord distance from the leading edge. Using a mesh giving only 14 mesh points on the airfoil, we find that the calculations yield a 12.06 percent airfoil at 28.2 percent of the chord distance from the leading edge.

Aeronautical Research Council (Gt. Brit.)
TESTS ON A WHIRLWIND AIRCRAFT IN THE ROYAL AIRCRAFT ESTABLISHMENT 24-FT WIND TUNNEL. (Includes: MOMENTUM INVESTIGATIONS ON FUSELAGE-WING INTERFERENCE AND NACELLE DRAG) T. V. Somerville, R. R. Duddy and G. H. L. Buxton. 1953. 17p. diagrs., 8 tabs. (ARC R & M 2603. Formerly RAE BA Dept. Note LWT 30; RAE BA Dept. Note LWT 34)

Simple modifications were found to decrease the drag of the airplane. The drag analysis is not complete and is focused chiefly on the drag due to leaks, cooling, and excrescences. A complete record of the tests is given. Modifications which gave an appreciable saving in drag were sealing of leaks and gaps, fairing of exhaust cooling ducts, and fairing of main cooling inlet. The saving in drag corresponds to an increase in maximum speed of about 15 mph. A further saving of 0.8 pound can be obtained by sealing the cartridge chutes.

THE INDUCED VELOCITY FIELD OF A ROTOR. K. W. Mangler and H. B. Squire. 1953. 16p. diagrs. (ARC R & M 2642; ARC 11,562; ARC 11,694. Formerly RAE Aero 2247; RAE Tech. Note Aero 1958)

A short account and the results of a theoretical investigation of the velocity field induced by a lifting rotor are given. The computation is based on the assumptions that the rotor is lightly loaded and that is has an infinite number of blades. This is applied to calculate the induced velocity distribution for disk incidences of 0°, 15°, 30°, 45°, and 90°. For the downwash at the rotor itself (the normal component of the induced velocity) the Fourier coefficients are given, as they are needed for the calculation of the blade motion.

MEASUREMENTS OF THE AERODYNAMIC DERIVATIVES FOR A HORN-BALANCED ELEVATOR. N. C. Lambourne, A. Chinneck and D. B. Betts. 1953. 15p. diagrs., photos., 2 tabs. (ARC R & M 2653. Formerly ARC 12,085; 0.796)

This report gives the results of measurements by a forced oscillation method of the direct derivatives (aerodynamic stiffness and damping) for a horn-balanced elevator. The tests were made at low airspeeds on a complete wing-fuselage-tail model at 0° and 10° incidence in a wind tunnel. Some information was obtained on the effect of mean elevator angle on the derivatives when the model was at the high incidence. Measurements were also made with trailing-edge cords and transition wires in position. The experiments suggest that none of the above factors causes a reduction in damping, but the stiffness derivative was found to be considerably influenced by the elevator angle and by the presence of trailing-edge cords and transition wires. In general, the measured values are numerically considerably less than those calculated by simple strip theory using two-dimensional vortex sheet theory results.

MULTIPLE-JET WHITE-SMOKE GENERATORS. C. Salter. 1953. 18p. diagrs., photos. (ARC R & M 2657. Formerly ARC 10,296; FM 1058; ARC 13,004; FM 1425)

Descriptions are given of equipment devised for the generation of fairly large quantities of an optically dense white smoke and special attention has been paid to the need for delivering this through long ducts or against an appreciable back-pressure. The smoke consists of very small particles of condensed paraffin vapor and is obtained by directing jets of cool air on to high-speed jets of the vapor issuing from very small orifices. The optimum outputs are about 6 cu ft (170 litres) and 8 cu ft (230 litres) per minute from No. 1 and No. 2 generators, respectively, but considerably larger quantities can be delivered

with a slight loss of opacity. Under normal operating conditions, the rate of use of paraffin is rather less than 2 cu in. (33 c.c.) (No. 1) and 3 cu in. (49 c.c.) (No. 2) per minute.

Aeronautical Research Council (Gt. Brit.)
AIR COOLING METHODS FOR GAS TURBINE COMBUSTION SYSTEMS. F. J. Bayley. 1953. 44p. diagrs. (ARC CP 133)

An account is given of the whole of the work which has been done at NGTE on the problem of air-cooling gas combustion systems. Each of the different methods of wall cooling is discussed separately and the theory and mechanism of the cooling process is developed from first principles. It is shown that "sweat," or effusion cooling, is by far the most effective and efficient method, while the use of "louvered" surfaces represents the nearest practical approach to this ideal which is possible while suitable porous materials remain unavailable.

N-28553*

Aeronautical Research Council (Gt. Brit.)
THE MEASUREMENT OF HEAT TRANSFER AND SKIN FRICTION AT SUPERSONIC SPEEDS. PART III. MEASUREMENTS OF OVERALL HEAT TRANSFER AND OF THE ASSOCIATED BOUNDARY LAYERS ON A FLAT PLATE AT M_1 = 2.43. R. J. Monaghan and J. R. Cooke. 1953. 63p. diagrs., 3 tabs. (ARC CP 139)

A mean value of 0.906 was obtained for temperature recovery factor and the overall heat transfer measurements from plate to stream agreed well with results from the low-speed formula of reference 2. There was some forward movement of boundary-layer transition, a variation in the exponent of the turbulent velocity distribution, and an increase in displacement thickness with heat transfer. However, no decrease in skin friction below its zero heat transfer value was found.

THE THEORY OF AEROFOILS WITH HINGED FLAPS IN TWO-DIMENSIONAL COMPRESSIBLE FLOW. L. C. Woods. 1953. 32p. diagrs. (ARC CP 138)

Recently published methods of deducing practical values of the various control characteristics from a knowledge of their theoretical values increases the importance of the theory of two-dimensional controls in an inviscid compressible fluid. The classical work of Glauert neglects compressibility and airfoil thickness, and while the more recent work of Goldstein and Preston includes thickness effects, it ignores compressibility. Furthermore, this latter method achieves accuracy for thick airfoils at the cost of a complicated method of calculation. This paper presents a theory of two-dimensional controls in compressible flow which is almost as simple to apply as Glauert's theory. An example given by Goldstein and Preston is treated by the author's method to illustrate this point.

Aeronautical Research Council (Gt. Brit.)
THE PERFORMANCE OF SOME TYPICAL TURBOJET ENGINE EXHAUST SYSTEMS, WITH PARTICULAR REFERENCE TO THE EFFECTS OF SWIRL. P. F. Ashwood and P. J. Fletcher. 1953. 28p. diagrs., 3 tabs. (ARC CP 130)

Tests made to determine the effect of swirl on the performance of a quarter-scale model of a typical turbojet engine exhaust system and propelling nozzle are described. The losses in the system were derived from direct measurement of thrust. The nondimensional thrust, expressed in terms of the nozzle area and the total pressure at inlet to the exhaust diffuser, was found to vary linearly with the ratio of ambient to inlet total pressures. An annular nozzle was found to give slightly over 2 percent more thrust at the choking condition than the standard system for the same air mass flow.

PROPOSED METHOD FOR DEFINING THE TAPER RATIO OF MONOPLANE WINGS. (Una Proposta per la determinazione del rapporto di rastremaxione delle ali monoplane). Giuseppe Gabrielli. February 1954. 14p. diagrs. (Trans. from Onore di Modesto Panetti, 1950, p. 67-71)

A definition is given of taper ratio applicable to all plan forms included within a double infinity of analytically defined wings. A method of plotting the plan form of a wing for which area, span, and taper ratio values are given is described. The author defines an equivalent wing to which static, aerodynamic, aeroelastic, and weight calculations may be referred in first approximation for any wing.

DECLASSIFIED REPORTS

NACA RM L6L26

FREE-FALL MEASUREMENTS AT TRANSONIC VELOCITIES OF THE DRAG OF A WING-BODY CONFIGURATION CONSISTING OF A 45° SWEPTBACK WING MOUNTED FORWARD OF THE MAXIMUM DIAMETER ON A BODY OF FINENESS RATIO 12. Charles W. Mathews and Jim Rogers Thompson. April 2, 1947. 18p. diagrs., photo. (NACA RM L6L26) (Declassified from Confidential, 11/10/53)

The National Advisory Committee for Aeronautics is measuring drag of a series of complete airplane-like configurations and their various components at transonic velocities by the free-fall method. This report covers a test of one configuration of this series. The configuration was composed of a 45° sweptback wing of aspect ratio 4.1 mounted forward of the maximum diameter of a 10-inch-diameter body of fineness ratio 12 equipped with stabilizing tail fins. The wing has a 70-inch span and incorporated an NACA 65-009 airfoil section of 12-inch chord perpendicular to the leading edge. The body-tail fin combination was externally identical with a combination tested previously by this method.

NACA RM L7C25a

TESTS OF A HORIZONTAL-TAIL MODEL THROUGH THE TRANSONIC SPEED RANGE BY THE NACA WING-FLOW METHOD. Richard E. Adams and Norman S. Silsby. April 11, 1947. 24p. diagrs., photos., tab. (NACA RM L7C25a) (Declassified from Restricted, 11/10/53)

A semispan model of the horizontal tail of a fighter airplane was tested at transonic speeds. Measurements of lift, elevator hinge moment, angle of attack, and elevator angle were made in the Mach number range from 0.75 to 1.04 for elevator deflections ranging from 10° to -10° and for angles of attack of -1.2°, 0.4°, and 3.4°. The hinge moment data are considered to be only qualitative.

NACA RM L7D22

SOME PRESSURE-DISTRIBUTION MEASUREMENTS ON A SWEPT WING AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. J. Ford Johnston and Edward C. B. Danforth. June 6, 1947. 21p. diagrs., photos. (NACA RM L7D22) (Declassified from Restricted, 11/10/53)

First results are given of chordwise pressure-distribution measurements on a 45° sweptback wing at transonic speeds. These tests are part of a fundamental investigation of flow phenomena near sonic velocity by the NACA wing-flow method. Distributions were obtained at two spanwise extensions of the half-span model of 2-inch chord and NACA 65-210 airfoil section measured perpendicular to the leading edge. The aspect ratios were 2.1 and 3.5.

CURRENT NACA REPORTS

NACA Rept. 1114

A THERMODYNAMIC STUDY OF THE TURBINE-PROPELLER ENGINE. Benjamin Pinkel and Irving M. Karp. 1953. ii, 36p. diagrs. (NACA Rept. 1114. Formerly TN 2653)

Equations and charts are presented for computing performance parameters of a turbine-propeller engine for any given set of operating conditions and component efficiencies. In order to illustrate some of the turbine-propeller system performance characteristics, the total thrust horsepower per unit mass rate of air flow and the specific fuel consumption are presented for a wide range of flight engine design operating conditions and given design component efficiencies. The performance of a turbine-propeller engine containing a matched set of components is presented for a range of engine operating conditions. The influence of the characteristics of the individual components of off-design-point performance is shown. The flexibility of operation of two turbine-propeller engines is discussed; one engine has a divided turbine system in which the first turbine drives only the compressor and the second turbine independently drives the propeller, and the other engine has a connected turbine system which drives both the compressor and the propeller.

NACA Rept. 1115

DESIGN OF TWO-DIMENSIONAL CHANNELS WITH PRESCRIBED VELOCITY DISTRIBUTIONS ALONG THE CHANNEL WALLS. John D. Stanitz. 1953. ii, 40p. diagrs., 8 tabs. (NACA Rept. 1115. Formerly TN 2593; TN 2595)

A general method of design is developed for two-dimensional unbranched channels with prescribed velocities as a function of arc length along the channel walls. The method is developed for both compressible and incompressible, irrotational, nonviscous flow and applies to the design of elbows, diffusers, nozzles, and so forth. Two types of compressible flow are considered: the general type, with the ratio of specific heats equal to 1.4, for example, and the linearized type, in which the ratio of specific heats is -1.0. Two methods of solution are used. In part I, solutions are obtained by relaxation methods and in part II, solutions are obtained by a Green's function.

NACA Rept. 1116

APPLICATION OF A CHANNEL DESIGN METHOD TO HIGH-SOLIDITY CASCADES AND TESTS OF AN IMPULSE CASCADE WITH 90° OF TURNING. John D. Stanitz and Leonard J. Sheldrake. 1953. ii, 20p. diagrs., photos., 2 tabs. (NACA Rept. 1116. Formerly TN 2652)

A technique is developed for the application of a channel design method to the design of high-solidity cascades with prescribed velocity distributions as a function of arc length along the blade-element profile. The technique applies to both incompressible and subsonic linearized compressible (ratio of specific heats equal to -1.0), nonviscous, irrotational, fluid motion. An impulse cascade with 90° turning was designed for incompressible flow and was tested at the design angle of attack over a range of downstream Mach number from 0.2 to choke flow. To achieve good efficiency, the cascade was designed for prescribed velocities with maximum allowable blade loading according to limitations imposed by considerations of boundary-layer separation.

NACA Rept. 1124

DISPLACEMENT EFFECT OF A THREE-DIMENSIONAL BOUNDARY LAYER. Franklin K. Moore. 1953. ii, 5p. diagrs. (NACA Rept. 1124. Formerly TN 2722)

A method is described for determining the "displacement surface" of a known three-dimensional compressible boundary-layer flow in terms of the mass-flow defects associated with the profiles of the two velocity components parallel to the surface. The result is a generalization of the plane flow concept of displacement thickness introduced in order to describe how a thin boundary layer distorts the outer nonviscous flow. Numerical values are found for the known three-dimensional boundary-layer flow about a cone at a small angle of attack to a supersonic stream.

NACA Rept. 1127

ONE-DIMENSIONAL ANALYSIS OF CHOKED-FLOW TURBINES. Robert E. English and Richard H. Cavicchi. 1953. ii, 18p. diagrs. (NACA Rept. 1127. Formerly TN 2810)

AVAILABLE ON LOAN ONLY.
DDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE;
E REPORT TITLE AND AUTHOR.

It is indicated that the area ratios and equivalent blade speed are the controlling factors in the design and operation of high work output turbines. For the usual class of turbine, increasing the equivalent blade speed of a given stage makes the internal flow conditions less critical. Flow conditions within choked-flow turbines are not usually sensitive to manufacturing errors in area ratio even near the stator choking limit. Six criteria are stated that will aid in establishing from test data of multistage turbines which blade rows are choked and which are not. The variation in internal flow conditions with operating conditions for a turbine equipped with an adjustable stator is determined for one application of stator adjustment.

NACA Rept. 1130

SOME EFFECTS OF FREQUENCY ON THE CONTRIBUTION OF A VERTICAL TAIL TO THE FREE AERODYNAMIC DAMPING OF A MODEL OSCILLATING IN YAW. John D. Bird, Lewis R. Fisher and Sadie M. Hubbard. 1953. ii, 17p. diagrs., photo. (NACA Rept. 1130. Formerly TN 2657)

The directional damping and stability of a fuselage - vertical-tail model oscillating freely in yaw were measured at a Mach number of 0.14 and compared with the damping and stability obtained by consideration of the effects of unsteady lift. The effects of vertical-tail aspect ratio and compressibility as predicted by the theoretical treatments are discussed in relation to the experimental stability characteristics obtained by the free-oscillation and by the curved-flow procedures.

NACA TN 3073

EXPERIMENTAL STRESS ANALYSIS OF STIFFENED CYLINDERS WITH CUTOUTS. PURE BENDING. Floyd R. Schlechte and Richard Rosecrans. March 1954. 41p. diagrs., photo., 7 tabs. (NACA TN 3073)

Bending tests were made on a cylindrical semimonocoque shell of circular cross section. The cylinder was tested without a cutout and then with a rectangular cutout which was successively enlarged through six sizes varying from 30° to 130° in circumference and from 1 to 2 bays in length. Strain measurements were made with resistance-type wire strain gages near the cutout on the stringers, the skin, and the rings for each size of cutout, and the stresses obtained are presented in tables.

NACA TN 3074

A PRELIMINARY INVESTIGATION OF THE EFFECTS OF GUSTY AIR ON HELICOPTER-BLADE BENDING MOMENTS. Joseph W. Jewel, Jr. and Paul J. Carpenter. March 1954. 28p. diagrs., photos. (NACA TN 3074)

A preliminary investigation has been made at the Langley helicopter test tower to determine the bending moments excited on typical helicopter rotor blades in quiet and gusty air. The results obtained from this investigation indicate that the effects of gusts on rotor-blade bending moments appear to be secondary compared with the vibratory moments attributed to the unsymmetrical rotor downwash for the 26-mph condition tested and analyzed. It was also found that the addition of weights at the blade tips reduced the magnitude of the blade vibratory bending moments.

NACA TN 3075

MEASUREMENTS OF PRESSURE AND TEMPERATURE FOR APPRAISAL OF THE TEMPERATURE METHOD OF AIRSPEED CALIBRATION IN THE LOWER STRATOSPHERE. Lindsay J. Lina. March 1954. 12p. diagrs., photo. (NACA TN 3075)

An investigation was made to determine whether the temperature and pressure conditions in the lower stratosphere would meet the requirements of the temperature method for accurate calibration of airspeed installations. Measurements of temperature and pressure were made in flights of a swept-wing fighter airplane on four clear days in March and April 1953 over land near Langley Field, Virginia. The results indicated that, although the temperature lapse rate was favorable to the method, large and erratic variations of temperature with time and distance precluded accurate calibration. Unfavorable atmospheric conditions had also been found previously in an investigation of the upper troposphere (NACA TN 2807).

NACA TN 3096

THEORETICAL PREDICTION OF PRESSURE DISTRIBUTIONS ON NONLIFTING AIRFOILS AT HIGH SUBSONIC SPEEDS. John R. Spreiter and Alberta Alksne. March 1954. (ii), 84p. diagrs. (NACA TN 3096)

Theoretical pressure distributions on nonlifting circular-arc airfoils in flows with high subsonic free-stream velocity are found by determining approximate solutions of an integral equation for transonic flow proposed by Oswatitsch. Solutions are obtained using an iteration process which differs from the classical methods in that the quadratic nature of the integral equation is recognized. Except for phenomena which are predominantly influenced by viscous effects, the results are in good accord with experimental data.

NACA TN 3097

TURBULENT BOUNDARY-LAYER AND SKIN-FRICTION MEASUREMENTS IN AXIAL FLOW ALONG CYLINDERS AT MACH NUMBERS BETWEEN 0.5 AND 3.6. Dean R. Chapman and Robert H. Kester. March 1954. 53p. diagrs., photos., 5 tabs. (NACA TN 3097)

Direct-force measurements have been made of the average skin-friction coefficient for completely turbulent flow along the cylindrical portion of heat-insulated cone-cylinder bodies of revolution having overall fineness ratios of 10, 15, and 25. Numerous boundary-layer surveys were made. Reynolds numbers between 4 million and 32 million were investigated. At a Mach number of 2.0, data were obtained for different pressure distributions by distorting the flexible-plate walls of the wind tunnel. The results show no significant effect of small pressure gradients and only a small effect of cylinder fineness ratio on the average skin-friction coefficient. For each fineness ratio the effect of Mach number is large and essentially the same for all Reynolds numbers investigated. Determinations of friction by the momentum method differed considerably from the more reliable direct-force measurements.

NACA TN 3099

IMPINGEMENT OF WATER DROPLETS ON AN ELLIPSOID WITH FINENESS RATIO 5 IN AXISYMMETRIC FLOW. Robert G. Dorsch, Rinaldo J. Brun and John L. Gregg. March 1954. 50p. diagrs., tab. (NACA TN 3099)

The presence of radomes and instruments that are sensitive to water films or ice formations in the nose section of all-weather aircraft and missiles necessitates a knowledge of the droplet impingement characteristics of bodies of revolution. Because it is possible to approximate many of these bodies with an ellipsoid of revolution, droplet trajectories about an ellipsoid of revolution with a fineness ratio of 5 were computed for incompressible axisymmetric air flow. From the computed droplet trajectories, the following impingement characteristics of the ellipsoid surface were obtained and are presented in terms of dimensionless parameters: (1) total rate of water impingement, (2) extent of droplet impingement zone, (3) distribution of impinging water, and (4) local rate of water impingement.

NACA TN 3100

STATISTICAL STUDY OF TRANSITION-POINT FLUCTUATIONS IN SUPERSONIC FLOW. J. C. Evvard, M. Tucker and W. C. Burgess, Jr. Appendix B. MATHEMATICAL PROCEDURES. Hugo Heermann. March 1954. 32p. diagrs., photos., tab. (NACA TN 3100)

The random movement of the transition point on a 10° cone at a free-stream Mach number of 3.12 was investigated by means of a large number of high-speed schlieren photographs. The distribution functions which statistically define the transition-point location were determined for a range of test-section Reynolds number and two levels of free-stream turbulence intensity. The intensity was varied by changing tunnel settling-chamber configurations. Temperature-recovery-factor distributions were also obtained. The axial extent of the distribution function determined from the schlieren data increased with turbulence level. The axial spread of the transition region denoted by the recovery-factor measurements roughly corresponded to that of the appropriate distribution function. These data suggest that a relatively sharp transition from laminar to turbulent flow takes place and that this flow pattern moves randomly along the aerodynamic surface. With the use of the statistical distribution functions obtained from the data and surface temperatures (as time-averaged by the surface thermocouples), the instantaneous surface-temperature distributions were calculated for two Reynolds numbers.

NACA TN 3102

AN ANALYTICAL AND EXPERIMENTAL STUDY OF THE TRANSIENT RESPONSE OF A PRESSURE-REGULATING RELIEF VALVE IN A HYDRAULIC CIRCUIT. Harold Gold and Edward W. Otto. March 1954. 54p. diagrs., photo., 3 tabs. (NACA TN 3102)

The transient response of the pressure-regulating relief valve in a hydraulic circuit is analyzed by means of an electrical analogy of the hydraulic circuit. Measurements of the transient response of a hydraulic relief valve are presented and are compared with responses calculated from the differential equation of the equivalent electric network. The comparison of experimental and analytical responses shows that the response of the relief valve can be adequately predicted by means of the equivalent network. The analysis of a typical relief valve by means of the equivalent network indicates that viscous damping is negligible and that the principle damping is derived from the flow resistance of the various elements of the hydraulic circuit. An expression is analytically developed that yields directly the area-lift relation for the relief valve for stable valve operation over the wide flow-rate ranges.

NACA TN 3103

COOLING REQUIREMENTS FOR STABILITY OF LAMINAR BOUNDARY LAYER WITH SMALL PRESSURE GRADIENT AT SUPERSONIC SPEEDS. George M. Low. March 1954. 16p. diagrs., tab. (NACA TN 3103)

The amount of cooling required to stabilize the two-dimensional supersonic laminar boundary layer for all Reynolds numbers is calculated for flows with pressure gradients of a magnitude usually encountered over slender aerodynamic shapes. Only two-dimensional disturbances are treated in the stability calculations. It is determined that small pressure gradients have an appreciable effect on stability. The cooling due to radiation alone may suffice, at moderate supersonic Mach numbers, to completely stabilize the boundary layer over wings with favorable pressure gradients. For flows with adverse pressure gradients, the cooling required for complete stability is considerably greater than that for flat-plate flows.

NACA TN 3104

EXPERIMENTAL INVESTIGATION OF SUBLIMATION OF ICE AT SUBSONIC AND SUPERSONIC SPEEDS AND ITS RELATION TO HEAT TRANSFER. Willard D. Coles and Robert S. Ruggeri. March 1954. 29p. diagrs., photo. (NACA TN 3104)

An experimental investigation was conducted in the 3.84- by 10-inch tunnel to determine the mass transfer by sublimation, heat transfer, and skin friction for an iced surface at subsonic and supersonic speeds. The results show that the Stanton numbers of sublimation and heat transfer were increased 40 to 50 percent for an iced surface of moderate roughness as compared with those obtained for a bare plate. For ice surfaces of equivalent roughness, the ratio of sublimation to heat-transfer Stanton numbers was found to be 0.90. Sublimation Stanton numbers obtained at a Mach number of 1.3 showed no appreciable deviation from those obtained at subsonic speeds. Sublimation as a means of removing ice formations of appreciable thickness is so slow as to be of little value in the de-icing of aircraft at high altitudes.

NACA TN 3105

AERODYNAMICS OF SLENDER WINGS AND WING-BODY COMBINATIONS HAVING SWEPT TRAILING EDGES. Harold Mirels. March 1954. ii, 96p. diagrs. (NACA TN 3105)

A general method, based on two-dimensional cross-flow concepts, is presented for obtaining the lift and moments on highly swept wings. Emphasis is placed on obtaining solutions for wings having swept trailing edges. The method is applicable for all problems where the velocity boundary conditions can be made homogeneous by differentiation in the streamwise or spanwise directions. Lift, roll, and pitch solutions, for highly swept wings, are presented. Both direct problems and inverse problems are considered. Applications of the method for the solution of wing-body problems and unsteady two-dimensional incompressible flow problems are also indicated.

NACA TN 3107

EFFECT OF HEAT TREATMENT UPON THE MICROSTRUCTURE AND HARDNESS OF A WROUGHT COBALT-BASE ALLOY STELLITE 21 (AMS 5385). F. J. Clauss and J. W. Weeton. March 1954. 26p. diagrs., photos. (NACA TN 3107)

An investigation has been made to study the response of wrought Stellite 21 to heat treatment. A period of 72 hours at 2250° F was sufficient for effective solution treatment of this alloy. Pearlitic structures formed at grain boundaries of solution-treated specimens during isothermal transformation at 1950°, 1750°, and 1500° F. A Widmanstaetten structure also formed during transformation at 1750° and 1500° F. Little visible precipitate formed by transformation at 1200° F for times up to 72 hours. Water quenching from 2250° F followed by aging at temperatures from 1200° to 1950° F resulted in precipitation principally along slip lines and twin boundaries. Spheroidization and agglomeration of precipitates occurred at temperatures as low as 1500° F. Isothermal or aging treatments above 1200° F increased the hardness of the solution-treated specimens. A maximum hardness of Rockwell C-42 was developed by aging 72 hours in the temperature range from 1400° to 1500° F, as compared to Rockwell C-20 to C-22 for the solution-treated condition. Overaging or softening occurred within 72 hours at temperatures of 1750° F and above for aging, and 1950° F for isothermal transformation.

NACA TN 3108

RELATION OF MICROSTRUCTURE TO HIGH-TEMPERATURE PROPERTIES OF A WROUGHT COBALT-BASE ALLOY STELLITE 21 (AMS 5385). F. J. Clauss and J. W. Weeton. March 1954. 49p. diagrs., photos., tab. (NACA TN 3108)

An investigation was conducted to determine the effects of microstructure on stress-rupture life of heat-treated wrought Stellite 21. Wrought Stellite 21, which may be considered a typical cobalt-base precipitation-hardening alloy, was found to respond readily to solution treatment and to isothermal and aging heat treatments to form pearlitic and Widmanstätten structures as well as scattered precipitates. The results obtained in this investigation, although determined specifically for the alloy wrought Stellite 21, lead to conclusions that are believed to have general significance in the heat treatment of other high-temperature alloys. The optimum high-temperature properties are associated with a dispersion of fine precipitate scattered throughout the grains of the microstructure. Such scattered precipitation was produced by solution treatment followed by a low-temperature aging treatment to develop nucleation sites and higher-temperature age to develop visible precipitation in the scattered nucleation sites.

NACA TN 3109

AN INVESTIGATION OF LAMELLAR STRUCTURES AND MINOR PHASES IN ELEVEN COBALT-BASE ALLOYS BEFORE AND AFTER HEAT TREATMENT. J. W. Weeton and R. A. Signorelli. March 1954. 50p. diagrs., photos., 12 tabs. (NACA TN 3109)

An investigation of the occurrence and nature of lamellar structures and minor phases of eleven cobalt-base high-temperature alloys (rolled, cast, and high-carbon Stellite 21, 422-19, X-63, 6059, 61, X-40, S-816, I-336, and J). The minor phases TaC, NbC, Cr_3C_2, Cr_7C_3, $Cr_{23}C_6$, M_6C, Cr_2O_3 type oxides, spinels, and sigma were identified by X-ray diffraction analysis. Sigma phase patterns appeared strongest where large numbers of carbides were also present, indicating that carbide precipitation may facilitate sigma phase formation. The most prevalent carbide indicated was $Cr_{23}C_6$. One of the two phases of the pearlitic structure consisted predominantly of the carbide $Cr_{23}C_6$.

NACA TN 3111

FRICTION AND WEAR INVESTIGATION OF MOLYBDENUM DISULFIDE. II - EFFECTS OF CONTAMINANTS AND METHOD OF APPLICATION. Marshall B. Peterson and Robert L. Johnson. March 1954. 19p. diagrs., photos., tab. (NACA TN 3111)

An experimental study was conducted using a low-speed kinetic-friction apparatus to show the effects of method of application and contaminants on the lubricating characteristics of molybdenum disulfide MoS_2. Friction coefficients for a purified grade of MoS_2 can vary from 0.025 to 0.12 merely by changing the method of application. Contaminants present in commercial grades of MoS_2 do not increase friction but can (for example, 0.5 percent silica) adversely affect wear. In room atmosphere, small amounts of oil (5 to 10 percent) reduce friction below that obtained with either purified MoS_2 or with oil alone. At least 10 percent MoS_2 should be present in the oil to obtain the lowest friction. The lowest friction values were obtained at the highest temperatures used (300° F) where the adverse effects of moisture were minimized.

NACA TN 3112

ANALOG STUDY OF INTERACTING AND NON-INTERACTING MULTIPLE-LOOP CONTROL SYSTEMS FOR TURBOJET ENGINES. George J. Pack and W. E. Phillips, Jr. March 1954. 33p. diagrs., photos. (NACA TN 3112)

An analog investigation of several turbojet control configurations was made. Both proportional and proportional-plus-integral controllers were studied, and compensating terms for engine interaction were added to the control system. Data were taken on the stability limits and the transient responses of these various configurations. Analytical expressions in terms of the component transfer functions were developed for the configurations studied and the optimum form for the compensation terms was determined. It was found that the addition of the integral term, while making the system slower and more oscillatory, was desirable in that it made the final values of the system parameters independent of source of disturbance and also eliminated droop in these parameters. Definite improvement in system characteristics results from the use of proper compensation terms. At comparable gain points the compensated system is faster and more stable. Complete compensation eliminates engine interaction permitting each loop to be developed to an optimum point independently.

NACA TN 3126

A DESIGN STUDY OF LEADING-EDGE INLETS FOR UNSWEPT WINGS. Robert E. Dannenberg. March 1954. 56p. diagrs., photos., 3 tabs. (NACA TN 3126. Formerly RM A9K02b)

A method is presented for calculating the profile coordinates for an inlet to be placed in the leading edge of an airfoil from formulas. The method includes an application of the principles of thin-airfoil theory which permits the change in velocity distribution caused by a variation in inlet profile to be calculated. Wind-tunnel tests of leading-edge inlets in an airfoil having the NACA 63_1-012 section were made to evaluate the effects of the inlets on the aerodynamic characteristics of the airfoil. The results indicated that the airfoil with an inlet devised by the design method had satisfactory aerodynamic characteristics.

NACA TN 3127

THE EFFECTIVENESS AT HIGH SUBSONIC MACH NUMBERS OF A 20-PERCENT-CHORD PLAIN TRAILING-EDGE FLAP ON THE NACA 65-210 AIRFOIL SECTION. Louis S. Stivers, Jr. March 1954. 15p. diagrs. (NACA TN 3127)

The lift-control characteristics of a 20-percent-chord plain trailing-edge flap on the NACA 65-210 airfoil section have been analyzed for Mach numbers from 0.30 to 0.875 utilizing section lift-coefficient data. In addition, the relative merits of the plain flap, a spoiler, and a dive-recovery flap employed separately as a lift-control device on the NACA 65-210 airfoil section have been determined from increments of section lift, drag, and pitching-moment coefficients which accompanied the deflection of each control device. The Reynolds number of the data varied with Mach number from about 1×10^6 to 2×10^6.

NACA TN 3129

INVESTIGATION OF A SLAT IN SEVERAL DIFFERENT POSITIONS ON AN NACA 64A010 AIRFOIL FOR A WIDE RANGE OF SUBSONIC MACH NUMBERS. John A. Axelson and George L. Stevens. March 1954. 35p. diagrs., photos., 7 tabs. (NACA TN 3129)

An investigation of a slat in several different positions on an NACA 64A010 airfoil has been conducted over a Mach number range from 0.25 to 0.85, corresponding to a Reynolds number range from 3.4 million to 8.1 million. Section force coefficients and chordwise distributions of pressure and resultant loading are presented for several different locations of the slat. The loading on the slat rather than the effects of the air flowing through the gap was found to be the primary factor determining slat performance.

NACA TN 3143

EXPERIMENTAL DETERMINATION OF THERMAL CONDUCTIVITY OF LOW-DENSITY ICE. Willard D. Coles. March 1954. 12p. diagrs., photo. (NACA TN 3143)

The thermal conductivity of low-density ice has been computed from data obtained in an experimental investigation of the heat transfer and mass transfer by sublimation for an iced surface on a flat plate in a high-velocity tangential airstream. The results are compared with data from several sources on the thermal conductivity of packed snow and solid glaze ice. The results show good agreement with the packed-snow values, and the extension of the curves for packed snow to the solid ice regime indicates that the curves are applicable to ice over the entire density range.

NACA TN 3162

EFFECTS OF SUBSONIC MACH NUMBER ON THE FORCES AND PRESSURE DISTRIBUTIONS ON FOUR NACA 64A-SERIES AIRFOIL SECTIONS AT ANGLES OF ATTACK AS HIGH AS 28°. Louis S. Stivers, Jr. March 1954. 145p. diagrs., photos., 8 tabs. (NACA TN 3162)

A high-speed wind-tunnel investigation has been made of the NACA 64A010, 64A410, 64A006, and 64A406 airfoil sections at angles of attack as high as 28°. Pressure-distribution, lift, drag, and moment characteristics were determined for each airfoil section at Mach numbers ranging from 0.30 to about 0.93, with corresponding Reynolds numbers varying from approximately 0.9×10^6 to 1.9×10^6. The $a = 0.8$ (modified) mean line was employed for the cambered airfoil sections.

NACA TN 3164

FURTHER STUDIES OF THE MECHANISM BY WHICH HYDROGEN ENTERS METALS DURING CHEMICAL AND ELECTROCHEMICAL PROCESSING. L. D. McGraw, W. E. Ditmars, C. A. Snavely and C. L. Faust, Battelle Memorial Institute. March 1954. 37p. diagrs., 4 tabs. (NACA TN 3164)

This investigation was a continuation of efforts to develop fundamental concepts which would be useful in preventing or alleviating hydrogen damage to steel. NACA Technical Note 2696 presented a new mechanism which postulates that the entry of hydrogen into metals from chemical and electrochemical action occurs when hydrogen-metal alloy formation is simultaneous with discharge (or release) of hydrogen atoms. In the present work the phenomena relating to hydrogen entry into steel were studied further. In general, the results support the newly postulated concepts.

NACA TN 3167

THERMAL CONDUCTANCE OF CONTACTS IN AIRCRAFT JOINTS. Martin E. Barzelay, Kin Nee Tong and George Hollo, Syracuse University. March 1954. 47p. diagrs., photos., 2 tabs. (NACA TN 3167)

Tests were conducted to determine the factors influencing the thermal conductance across the interface between 75S-T6 aluminum-alloy and AISI Type 416 stainless-steel structural joints. From the results it was concluded that (1) the thermal conductance of the interface joint increases with mean temperature level, while it remains approximately constant with changes in heat flow; (2) thin foils of good conducting materials inserted between the interfaces improve the heat transfer noticeably; (3) common strength-giving bonding materials produce joints with very poor thermal conductivity; and (4) none of the three modes of heat transfer (metal-to-metal conduction, air-film conduction, and radiation) has any predominance over another across the interface joints and, furthermore, there is an interdependence among these three which has not previously been recognized.

NACA TN 3177

ION TRACER TECHNIQUE FOR AIRSPEED MEASUREMENT AT LOW DENSITIES. W. B. Kunkel and L. Talbot, University of California. March 1954. 31p. diagrs. (NACA TN 3177)

A study has been made of the aerodynamic and production detection problems associated with ion tracer velocity measurement techniques, with particular emphasis on those aspects unique to low-density gas dynamics. A critical survey was made of the various techniques which have been employed and specific suggestions are offered relative to the successful use of ion tracer velocity measuring methods at low densities. A description is also included of some experimental work carried out with an ion-pulse airspeed indicator developed by the Ames Aeronautical Laboratory Low Pressures Group of the National Advisory Committee for Aeronautics for use in low-density wind tunnels.

NACA TN 3190

FATIGUE INVESTIGATION OF FULL-SCALE TRANSPORT-AIRPLANE WINGS. SUMMARY OF CONSTANT-AMPLITUDE TESTS THROUGH 1953. M. J. McGuigan, Jr., D. F. Bryan and R. E. Whaley. Appendix A. NOTES ON THE USE OF BONDED WIRES TO DETECT FATIGUE CRACKS. M. H. Levin. March 1954. 45p. diagrs., photos., 3 tabs. (NACA TN 3190)

Results are presented of constant-amplitude fatigue tests on the wings of C-46 airplanes. Eight complete wings were tested at four alternating load levels ranging from 7-1/2 to 22 percent of the design ultimate load factor. All tests were conducted with a 1 g mean load, which is about 22 percent of the design ultimate load factor. All failures which occurred are classified in five types according to the structural stress raisers in which they originated. Effective stress-concentration factors were determined for each stress raiser where failures occurred, the rate and manner of fatigue-crack propagation was investigated, and the effect of the magnitude of load on these items was determined. The scatter in fatigue life of the wings was analyzed statistically. The load-lifetime relationship of the test structure was compared with that of several other full-scale and component structures which have been subjected to fatigue tests. An appendix by M. H. Levin presents information on the use of bonded wires to detect small fatigue cracks; another appendix deals with the use of fiber glass as a method of structural repair.

NACA RM 53L22

ADDITIONAL FATIGUE TESTS ON EFFECTS OF DESIGN DETAILS IN 355-T6 SAND-CAST ALUMINUM ALLOY. I. D. Eaton and John A. Youra, Aluminum Company of America. March 1954. 24p. diagrs., photos., 5 tabs. (NACA RM 53L22)

Additional static and fatigue tests were made on aluminum-alloy 355-T6 sand-cast specimens. Direct stress fatigue tests were made on plate-type speci-

mens with a single 1-inch-diameter as-cast cored hole and on specimens in which the cored hole was reamed to 1-1/16 inch diameter. In addition, direct-stress fatigue tests were made on 0.300-inch-diameter specimens, with various degrees of porosity, machined from the butt ends of plate-type specimens. Comparisons are made with results of earlier tests, on plate-type specimens with variations in design details such as bosses and ribs, given in NACA Technical Note 2394.

EFFECT OF ICE FORMATIONS ON SECTION DRAG OF SWEPT NACA 63A-009 AIRFOIL WITH PARTIAL-SPAN LEADING-EDGE SLAT FOR VARIOUS MODES OF THERMAL ICE PROTECTION. Uwe H. von Glahn and Vernon H. Gray. March 1954. 59p. diagrs., photos. (NACA RM E53J30)

Studies were made to determine the effect of ice formations on the section drag of a 6.9-foot-chord 36° swept NACA 63A-009 airfoil with partial-span leading-edge slat. In general, the icing of a thin swept airfoil will result in greater aerodynamic penalties than for a thick unswept airfoil. Glaze-ice formations at the leading edge of the airfoil caused large increases in section drag even at a liquid-water content of 0.39 gram per cubic meter. The use of an ice-free parting strip in the stagnation region caused a negligible change in drag compared with a completely unheated airfoil. Cyclic de-icing when properly applied caused the drag to decrease almost to the bare-airfoil drag value.

NACA RM E53K24

KINETIC STUDY OF MASS TRANSFER BY SODIUM HYDROXIDE IN NICKEL UNDER FREE-CONVECTION CONDITIONS. Don R. Mosher and Robert A. Lad. March 1954. 14p. diagrs., photo., tab. (NACA RM E53K24)

An investigation was conducted using static capsules fabricated from "L" nickel tubing to determine the effect of temperature level, temperature gradient, and test duration on corrosion and mass transfer by molten sodium hydroxide under free-convection conditions. A base temperature range from 1000° to 1600° F with temperature differences to 500° was studied. The rate of mass transfer was found to be strongly dependent on both temperature level and gradient. The rate shows little tendency to decrease for test durations up to 200 hours, although the concentration of nickel in the melt approaches a limiting value after 100 hours.

NACA RM E53L21

PRELIMINARY INVESTIGATION OF THE "FREEZE-CASTING" METHOD FOR FORMING REFRACTORY POWDERS. W. A. Maxwell, R. S. Gurnick and A. C. Francisco. March 1954. 19p. diagrs., photos., 2 tabs. (NACA RM E53L21)

A method of preparing intricately shaped objects from refractory powders was investigated. The method consists in preparing an extremely thick slip with a small amount of binder, casting the slip into a mold, and freezing to retain the shape of the casting. The casting is then dried by sublimation and may subsequently be sintered by conventional means. It was found possible to cast high-solid-content slips by employing vibration during the casting process. Turbosupercharger blades of good appearance and free from radiographic flaws were produced. The factors affecting the density of a casting before sintering were determined.

NACA RM E53L21b

A FLOW CALORIMETER FOR DETERMINING COMBUSTION EFFICIENCY FROM RESIDUAL ENTHALPY OF EXHAUST GASES. Albert Evans and Robert R. Hibbard. March 1954. 21p. diagrs., 2 tabs. (NACA RM E53L21b)

A flow calorimeter for determining the combustion efficiency of turbojet and ram-jet combustors from measurement of the residual enthalpy of combustion of the exhaust gas is described. Briefly, the calorimeter catalytically oxidizes the combustible constituents of exhaust-gas samples, and the resultant temperature rise is measured. This temperature rise is related to the residual enthalpy of combustion of the sample by previous calibration of the calorimeter. Combustion efficiency can be calculated from a knowledge of the residual enthalpy of the exhaust gas and the combustor input enthalpy. An accuracy of ± 0.2 Btu per cubic foot was obtained with prepared fuel-air mixtures, and the combustion efficiencies of single turbojet combustors measured by both the flow-calorimeter and heat-balance methods compared within 3 percentage units. Flow calorimetry appears to be a suitable method for determining combustion efficiencies at high combustor temperatures where ordinary thermocouples cannot be used. The method is fundamentally more accurate than heat-balance methods at high combustion efficiencies and can be used to verify near-100-percent efficiency data.

THE LOSS IN CLIMB PERFORMANCE, RELATIVE TO THE OPTIMUM, ARISING FROM THE USE OF A PRACTICAL CLIMB TECHNIQUE. K. J. Lush. 1953. 12p. diagrs., 2 tabs. (ARC R & M 2756; ARC 12,563. Formerly AAEE/Res/243)

A practical climb technique will not in general comply with the condition for optimum climb performance and will give an inferior climb. An assessment of the loss of performance involved is, therefore, desirable. A practical climb technique is considered which is defined by a fixed relation between equivalent air speed (or Mach number) and pressure altitude, and a rough estimate made of the loss in performance involved in using such a technique with a turbine jet aircraft over a range of air temperature, engine speed, thrust, or aircraft weight. An approximate method of calculating a suitable relation is given in an appendix. If the technique for optimum climb is not fixed by compressibility effects, use of such a practical climb technique will result in a loss of performance, relative to the optimum, less than the greater of 1 percent and 1/2 ft/sec in rate of climb over a wide range of aircraft weight or a moderate range of air temperature, engine speed or thrust. Approximate limits are quoted in table 2. More precise limits may be estimated for any particular aircraft. If the technique for optimum climb is determined by compressibility effects such a practical climb technique can give optimum performance over a wide range of weight, air temperature, and engine speed.

THE ELASTIC STABILITY OF SANDWICH PLATES. J. H. Hunter-Tod. 1953. 39p. diagrs. (ARC R & M 2778; ARC 12,550. Formerly College of Aeronautics, Cranfield, Rept. 25)

This paper treats the elastic stability of supported rectangular plates of sandwich construction with isotropic and aeolotropic fillings under compression and shear loading. Formulas are developed for critical stresses for flat and curved panels in compression and flat panels in shear for the buckling of the whole panel, also for the wrinkling or local failure of the faces of flat panels in compression. It is established that for a wide range of conditions the critical stress for panels buckling in compression is independent of the form of the filling providing it is symmetrical about the normal; of the elastic constants of the filling only the transverse shear is of concern. As a result a simple extension of the equivalent plate theory of greatly improved accuracy is developed enabling the use of equations treating the plate as a whole.

THE TURBULENT BOUNDARY LAYER IN COMPRESSIBLE FLOW. W. F. Cope. 1953. 8p. diagrs., tab. (ARC R & M 2840; ARC 7634 (rev.). Formerly Nat. Physical Lab., Engineering Dept. rept.)

The flow of a compressible gas past a flat plate is investigated for a turbulent boundary layer. The local and mean skin-friction coefficients are calculated for both power and log laws of velocity distribution. The calculations show a considerable reduction of both coefficients with increasing M. In the course of the analysis, assumptions have been made whose accuracy is not proven, though they are consistent with those made in incompressible gas dynamics. The results are applied to calculate the contribution to f_R of skin friction for a typical projectile of various calibers. The calculation shows that it should be possible by a properly selected series of wind-tunnel and full-scale experiments to ascertain if the large reduction in skin friction occurs, but that it is unlikely that it will be possible to discriminate between the two hypotheses about velocity distribution.

FOUR STUDIES IN THE THEORY OF STRESS CONCENTRATION. H. L. Cox. January 1950. ii, 58p. diagrs., 9 tabs. (ARC R & M 2704. Formerly Nat. Physical Lab., Engineering Div. Repts. 359/48; 361/48; 360/48; 362/48; 444A/50)

The four papers comprised in this monograph are a study of some of the theoretical aspects of experimental work in progress in the National Physics Laboratory from 1937 to 1947. The greater part of the work is related to failure of materials by fatigue and chief attention is paid to this mode of failure. Parts II and IV deal with the development of means to compute the stress distribution in the neighborhood of holes, grooves, and fillets. Part I is mainly concerned with the effect of holes and internal flaws. Part III deals with the effect of surface irregularities on fatigue strength.

A THEORETICAL APPROACH TO THE DESIGN OF HYDROFOILS. C. H. E. Warren. 1953. 20p. diagrs., 5 tabs. (ARC R & M 2836; ARC 10,181. Formerly RAE Tech. Note Aero 1739; Tech. Note Aero 1826)

An investigation has been made into the application of the theory of thin sections to the design of hydrofoils having high cavitation speeds. Consideration is given to both symmetrical sections, which themselves are suitable for struts, and camber-lines, which, when used with the symmetrical sections, lead to cambered sections which are suitable for lifting surfaces. In all the aim has been to keep the peak local velocities to a minimum and the sections developed differ from "low-drag" airfoil sections mainly in that, being hydrofoils, the sections have sharp leading edges. The theoretical optimum section consists of an elliptic symmetrical section superimposed on a logarithmic camber-line. Typical practical sections will cavitate at a speed lower by about 5 knots than the theoretical optimum section of the same thickness/chord ratio and at the same lift coefficient. For strut sections, it is shown that sections having high cavitation speeds at zero incidence tend to be inferior to other sections at incidences as small as 2°. For lifting surface

sections it is shown that although a high cavitation speed demands a low design lift coefficient, a high loading at cavitation demands a high design lift coefficient. Operation above cavitation speeds or over wide ranges of lift coefficient is not considered.

WIND-TUNNEL TESTS ON THE PREVENTION OF BOUNDARY-LAYER SEPARATION BY DISTRIBUTED SUCTION AT THE REAR OF A THICK AEROFOIL (NPL 153). N. Gregory, R. C. Pankhurst and W. S. Walker. 1953. 7p. diagrs., tab. (ARC R & M 2788. Formerly ARC 13,446; Perf. 702; FM 1485)

Tests of a preliminary nature have been carried out on a 33-percent-thick symmetrical airfoil (NPL 153) with suction through a porous-surface from 0.80 chord to the trailing edge, which was rounded and fitted with a Thwaites flap. The distributed suction was found to prevent separation and to reduce the wake drag to zero. The overall effective drag (including an allowance for the power required for the suction) was reduced slightly, but still remains fairly high. No hysteresis was observed in the change of drag with suction quantity. The flap was essential to stabilize the flow: without it, the flow with suction was unsteady and the wake drag was appreciable. When the flap was deflected 20°, there was no increase in the suction quantity required to prevent separation.

ON THE LAMINAR BOUNDARY LAYER SEPARATION FROM THE LEADING EDGE OF A THIN AEROFOIL. P. R. Owen and L. Klanfer. October 1953. 19p. diagrs., 6 tabs. (RAE Aero 2508)

Low-speed wind tunnel tests have shown that when a laminar boundary layer separates from the leading edge of a thin airfoil at angle of attack, the flow often becomes attached to the surface again some distance downstream. It is suggested that the length of the "bubble" depends primarily on the Reynolds number based on the displacement thickness at the separation point. This Reynolds number in turn depends on the distance of the velocity peak on the upper surface of the airfoil from the stagnation point and it is inferred that, at a Reynolds number based on the chord, a long bubble is more likely to occur when the velocity peak is close to the stagnation point.

SUMMARY OF THE THEORETICAL WORK DONE ON THE STABILITY OF THIN PLATES, 1939 TO 1946. D. M. A. Leggett. 1953. 8p. (ARC R & M 2784. Formerly ARC 13,366; Strut 1376)

Attention is drawn to the more important problems of the stability of thin plates which were requiring solutions at the beginning of the war, and progress made towards their solution during the subsequent 7 years is indicated. Three types of problems are discussed: the critical buckling load of a flat rectangular plate when the edges are not all simply supported, the post-buckling behavior of a long flat plate under shear, and the initial and post-buckling behavior of a curved plate under various combinations of shear, compression, and normal pressure.

TESTS ON THE RELATIVE EFFICIENCY OF CHROMATE PIGMENTS IN ANTI-CORROSIVE PRIMERS. H. G. Cole. November 1953. 20p. diagr., 7 tabs. (RAE Tech. Note Met. 185)

Seawater spray corrosion tests have been made on two magnesium alloys, aluminum alloy, and mild steel, painted with primers made from 18 chromate pigments incorporated in turn in a litho-oil/coumarone medium. Best all round protection was given by zinc monoxy chromate, calcium chromate, and strontium chromate, and good protection by potassium zinc chrome (zinc yellow) and zinc tetroxy chromate. Four complex cadmium chromes and three lead chromates gave poor results. Of the zinc and alkaline earth pigments, those giving best protection were of intermediate solubility.

A NEW METHOD IN THE DYNAMICS OF A VISCOUS FLUID. (Novyi Metod v Dinamike Vyazkoi Zhidkosti). V. G. Nevzglyadov. 7p. (Trans. from Akademiia Nauk SSSR, Doklady, v. 77, no. 4, 1951, p.573-576)

The velocity vector of an incompressible fluid is written as the sum of two vectors; one satisfies the equation of potential flow, the other is small compared with the first. The flow equation is then obtained by replacing the velocity vector in the Navier-Stokes equation by the sum of these two vectors and neglecting products of the additional velocity vector and its derivatives. The resulting linear equation for the unknown additional velocity vector reduces to Oseen's when the vector obtained from the solution of the potential flow problem is replaced by the velocity vector very far from the body. The equation for the additional velocity vector is not solved; but it is assumed that, on a streamline near the body, the components of the additional velocity vector and their derivatives are determined by a polynomial approximation to the velocity components that is valid from this streamline to the surface of the body.

Cornell University, Graduate School of Aeronautical Engineering. ON THE RELATION AMONG STRESS, STRAIN, VELOCITY FROM TESTS ON COPPER WIRES SUBMITTED TO LONGITUDINAL IMPACT. C. Riparbelli. July 1953. (Rev.) 82p. diagrs., photos. (Cornell University, Graduate School of Aeronautical Engineering)

The relation among stress, strain and time rate of strain is found by experiments of tensile impact on copper wires. The results agree with the hypothesis that the velocity of propagation of a small disturbance is the same, whether the material is strained entirely within the elastic range or whether the disturbance is introduced and propagated in the presence of plastic flow. Results indicate that the rate of plastic flow is proportional to the excess of the strain.

AERODYNAMICS - THEORY, EXPERIMENT, APPLICATION. Hugh L. Dryden. 9p. diagrs., photos. (Reprint from Aeronautical Engineering Review, v. 12, no. 12, December 1953).

Typical examples from various time periods in the growth of aerodynamics in the first half-century of flight are given. For clarity, theory, experiment, and application are treated as separate lines of effort. Today the term aerodynamics is applied to this triplet of activities, which, starting as separate and almost distinct threads, are now thoroughly interwoven into the fabric of modern aerodynamics. The great strength of aerodynamics and aeronautical engineering lies in the close integration and teamwork of the three groups within the last 20 or 25 years.

HYDRODYNAMIC DIRECTIONAL BEHAVIOR OF A SWEPT PLANING-TAIL HULL. Donald D. Arabian. January 10, 1952. 15p. diagrs. (NACA RM L51F04) (Declassified from Confidential, 3/9/54)

A qualitative investigation of the low-speed directional behavior of a swept planing-tail hull was made in the Langley tank no. 2 in still water and still air with the use of a free self-propelled model. The configuration was directionally unstable over a range of low speed. It was, however, directionally controllable at all speeds by use of the rudder and elevator. Several modifications that were investigated did not improve the controllability.

NACA TN 3023

RESULTS OF EDGE-COMPRESSION TESTS ON STIFFENED FLAT-SHEET PANELS OF ALCLAD AND NONCLAD 14S-T6, 24S-T3, AND 75S-T6 ALUMINUM ALLOYS. Marshall Holt, Aluminum Company of America. April 1954. 18p. diagrs., photos., 2 tabs. (NACA TN 3023)

This investigation was made to augment data previously obtained on the compressive strengths of stiffened flat-sheet panels to include the range where ultimate strengths approach the compressive yield strengths of the materials. The sheet materials used were alclad and nonclad 14S-T6, 24S-T3, and 75S-T6. The ultimate strengths of the panels tested varied from 93.3 to 118.0 percent of the compressive yield strengths of the materials from which they were constructed. The ultimate strengths of these panels appear to be limited by the strengths of the rivets. Higher ultimate strengths might have resulted from the use of larger or stronger rivets or a smaller rivet spacing.

NACA TN 3070

EFFECTS OF PANEL FLEXIBILITY ON NATURAL VIBRATION FREQUENCIES OF BOX BEAMS. Bernard Budiansky and Robert W. Fralich. March 1954. 55p. diagrs. (NACA TN 3070)

Effects of local panel oscillations on bending and torsional vibrations of box beams with flexible covers and webs are investigated. Theoretical analyses of simplified models are made in order to shed light on the mechanism of coupling between local and overall vibrations and to derive results that can be used to estimate the coupling effects in box beams.

NACA TN 3071

THEORETICAL SUPERSONIC FORCE AND MOMENT COEFFICIENTS ON A SIDESLIPPING VERTICAL- AND HORIZONTAL-TAIL COMBINATION WITH SUBSONIC LEADING EDGES AND SUPERSONIC TRAILING EDGES. Frank S. Malvestuto, Jr. March 1954. 69p. diagrs., 2 tabs. (NACA TN 3071)

Formulas are obtained by means of linearized flow theory for the lateral force due to sideslip, the yawing moment due to sideslip, and the rolling moment due to sideslip for a tail arrangement composed of a vertical triangular surface attached to a horizontal triangular surface. The leading edges of the surfaces are subsonic; the trailing edges, supersonic. A series of design charts are presented for rapid estimates of the stability derivatives considered.

NACA TN 3077

THE EFFECT OF DYNAMIC LOADING ON THE STRENGTH OF AN INELASTIC COLUMN. William A. Brooks, Jr. and Thomas W. Wilder, III. March 1954. 29p. diagrs., 2 tabs. (NACA TN 3077)

The maximum loads of idealized inelastic H-section columns whose pinned ends approach each other at a constant rate are presented. The solutions indicate that as the rate of end displacement becomes smaller the dynamic buckling solutions approach the static solution as a lower limit. For all rates of end displacement investigated the static maximum load may be employed as a conservative estimate of the maximum column load.

NACA TN 3079

THE HYDRODYNAMIC CHARACTERISTICS OF MODIFIED RECTANGULAR FLAT PLATES HAVING ASPECT RATIOS OF 1.00 AND 0.25 AND OPERATING NEAR A FREE WATER SURFACE. Kenneth L. Wadlin, John A. Ramsen and Victor L. Vaughan, Jr. March 1954. 64p. diagrs., photos. (NACA TN 3079)

Results are presented from an investigation of the hydrodynamic forces and moments acting on modified rectangular flat plates with aspect ratios of 1.00 and 0.25 mounted on a single strut and operating near the free water surface. A simplified method of obtaining

*AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

the lift characteristics in unseparated flow at large depths is presented. This method shows very good agreement with the data. The experimental effects of changing the angle of attack, depth of submersion, and aspect ratio are presented. The effects of cavitation and two different types of high-angle leading-edge separation are also presented.

NACA TN 3081

THE ZERO-LIFT DRAG OF A 60° DELTA-WING—BODY COMBINATION (AGARD MODEL 2) OBTAINED FROM FREE-FLIGHT TESTS BETWEEN MACH NUMBERS OF 0.8 AND 1.7. Robert O. Piland. April 1954. 11p. diagrs., 2 tabs. (NACA TN 3081)

The zero-lift drag of a 60° delta-wing—body combination (designated AGARD model 2) has been determined by free-flight tests of two models between Mach numbers of 0.8 and 1.7. These Mach numbers correspond to Reynolds numbers, based on body length, of 4×10^6 and 12×10^6, respectively. An estimate of the drag of the configuration was made by summing the estimates of the drag of the various components. The agreement between measured and estimated drag is good.

NACA TN 3082

EXPERIMENTAL INVESTIGATION OF THE PURE-BENDING STRENGTH OF 75S-T6 ALUMINUM-ALLOY MULTIWEB BEAMS WITH FORMED-CHANNEL WEBS. Richard A. Pride and Melvin S. Anderson. March 1954. 30p. diagrs., photo., tab. (NACA TN 3082)

Experimental results are presented for the pure-bending strength of 53 multiweb beams of various proportions. The beams were fabricated from 75S-T6 aluminum-alloy sheet material and had channel-type webs which had been cold formed with bend radii of four times the web thickness. Local and wrinkling modes of buckling were observed prior to failure. All failures occurred with the formation of a trough in the compression skin extending across the web attachment flanges. The stress levels achieved at buckling and failure are discussed in terms of existing theory. Based upon the failure stresses, design charts are presented which permit rapid selection of the most efficient proportions for given values of an appropriate structural index.

NACA TN 3142

A FURTHER INVESTIGATION OF THE EFFECT OF SURFACE FINISH ON FATIGUE PROPERTIES AT ELEVATED TEMPERATURES. Robert L. Ferguson. March 1954. 27p. diagrs., photos., 3 tabs. (NACA TN 3142)

An investigation was conducted to evaluate the effects of surface roughness on fatigue properties of low carbon N-155 alloy with a grain size of A.S.T.M. 6 and of S-816 alloy with a grain size of A.S.T.M. 6 to 7. Fatigue studies were conducted at 80°, 1200°, 1350°, and 1500° F. In addition, an investigation of the effect of surface abrasion upon the character of residual stresses and of the effect of time and temperature upon the relief of these stresses was conducted. Compressive stresses were produced at right angles to the direction of abrasion. These residual compressive stresses, if of sufficient magnitude, in the surface of fatigue specimens improved fatigue strength at low temperatures. At elevated temperatures, however, these beneficial surface compressive effects were relieved and only the detrimental stress concentration effects produced by abrasion remained and reduced fatigue strength.

NACA TN 3144

COEFFICIENT OF FRICTION AND DAMAGE TO CONTACT AREA DURING THE EARLY STAGES OF FRETTING. II - STEEL, IRON, IRON OXIDE, AND GLASS COMBINATIONS. John M. Bailey and Douglas Godfrey. April 1954. 26p. diagrs., 4 tabs. (NACA TN 3144)

Experiments were conducted to study the early stages (up to 400 cycles) of fretting of steel-steel combinations at constant frequency, amplitude, load, and humidity. Pure iron, glass, and iron oxide powder compacts were used in supplementary experiments. The results of microscopic observation of the contact area, chemical analyses of fretting debris, and measurement of coefficient of friction are presented and lead to these conclusions: 1. Fretting starts with severe adhesion. The adhesion varies with the material combination, but is of primary importance because it precedes and initiates the other phenomena observed. 2. In the early stages of fretting, several other wear phenomena in addition to adhesion occur: plowing by protruding transferred material; formation of metallic and oxide debris; formation of films by compacting small particles into clearances in the contact area.

NACA TM 1362

ON THE SOUND FIELD OF A POINT-SHAPED SOUND SOURCE IN UNIFORM TRANSLATORY MOTION. (Über das Schallfeld einer gleichförmig-translatorisch bewegten punkförmigen Schallquelle). H. Hönl. April 1954. 44p. diagrs. (NACA TM 1362. Trans. from Annalen der Physik, issue 5, v. 43, 1943, p. 437-464).

A rigorous analysis presented of the excitation of sound by point sources moving in uniform translatory motion at subsonic or supersonic velocities through a two- or three-dimensional medium at rest. The construction of surfaces of constant phase is based upon Huyghens' principle in such a manner that the propagation in the medium at rest of the elementary waves emanating from the sound source is independent of the momentary state of motion of the sound source; hence, characteristic traits of the sound propagation may be understood even on the basis of simple geometric constructions.

NACA TM 1367

HEAT TRANSFER, DIFFUSION, AND EVAPORATION. (Wärmeübergang, Diffusion und Verdunstung). Wilhelm Nusselt. March 1954. 37p. diagrs. (NACA TM 1367. Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 10, no. 2, April 1930, p. 105-121).

The general similarity of heat and mass transfer (diffusion) processes is discussed, with particular reference to the lack of complete identity of the relations governing the two phenomena. It is indicated that, for example, the boundary conditions in the two cases at the surface of a body will not be the same. The correct equation of diffusion is given for various simple cases. Generalized relations for combined heat and mass transfer are then evolved for particular situations, comparisons being made among several different approaches to the problem. Finally, the effect of a buoyancy force field on the generalized relations is considered, with special reference to the evaporation of water.

NACA RM E54B01

TOOTH-TYPE NOISE-SUPPRESSION DEVICES ON A FULL-SCALE AXIAL-FLOW TURBOJET ENGINE. Edmund E. Callaghan, Walton Howes and Warren North. March 1954. 16p. diagrs., photos. (NACA RM E54B01)

A study of two jet-noise-suppression devices consisting of teeth projecting into the air stream was conducted on a current axial-flow turbojet engine. The sound fields obtained with both noise-suppression devices were similar and, when compared with a standard nozzle, showed a reduction in maximum sound pressure level downstream of the jet and increased levels on the sides and rear. The reduction in maximum sound pressure level was only 2 decibels, and the total radiated power from the toothed and standard nozzles was almost identical (±1 db). It was concluded, therefore, that the toothed devices investigated do not represent a satisfactory solution of the jet-noise problem.

THE 9 x 3 IN. INDUCED-FLOW HIGH-SPEED WIND TUNNEL AT THE NATIONAL PHYSICAL LABORATORY. D. W. Holder and R. J. North. 1953. 23p. diagrs., photos., 9 tabs. (ARC R & M 2781. Formerly ARC 12,387; TP 285)

A 9 x 3 inch high-speed wind tunnel driven by a compressed-air injector has been built in the Aerodynamics Division of the National Physical Laboratory. The tunnel operates at roughly atmospheric stagnation pressure and has so far been used to give Mach numbers up to 1.8. The general arrangement of the tunnel and the preliminary calibration, which is generally satisfactory, are described.

BRITISH PERFORMANCE REDUCTION METHODS FOR MODERN AIRCRAFT. D. Cameron. 1953. 32p., diagrs., 5 tabs. (ARC R & M 2447; ARC 6445. Formerly AAEE/Res/170)

The methods of reduction of performance measurements to standard conditions applicable to aircraft with highly supercharged engines and constant-speed propellers are the subject of this report. The theory of the agreed methods is summarized in brief form, tables are given from which the necessary charts can be constructed, and the practical method of applying the corrections is described. The report does not include methods appropriate to certain aircraft and engines of later development (turbosuperchargers, turbine engines, and high-speed aircraft).

THE THEORETICAL EFFECT OF FLIGHT PATH ANGLE ON THE LATERAL STABILITY AND RESPONSE OF AN AIRCRAFT. E. M. Frayn and M. V. Parnell. 1954. 28p. diagrs., 8 tabs. (ARC R & M 2529; ARC 9360. Formerly RAE Aero 2097)

The response of a typical aircraft of the dive-bomber class to various disturbances has been calculated at four angles of dive covering the range 0° to 90° and for four pairs of values of ι_V, n_V. The most notable effect on stability is the marked increase in spiral damping with increasing dive angle at the same T.A.S. This has little effect on the response, since in most components, this mode is scarcely excited. For dive angles up to 30°, the variations in response are so slight as to be negligible, while for larger angles of dive, the variation is small for the first 2 airsecs. Calculations of response in level flight, which slightly underestimate the response in a dive, can thus be assumed to give a sufficiently accurate picture of the behavior at small flight path angles for most requirements.

INVESTIGATION OF LATERAL AND DIRECTIONAL BEHAVIOUR OF SINGLE ROTOR HELICOPTER (HOVERFLY MK. I). J. Zbrozek. 1953. 20p. diagrs., tab. (ARC R & M 2509; ARC 11,701. Formerly RAE Aero 2268)

This note gives an elementary theory of the lateral and directional stability and control of the single rotor helicopter with particular reference to the Sikorsky R4-B. The results of the analysis give good qualitative agreement with flight tests. Preliminary flight tests show higher damping and higher frequency of oscillations than predicted by theory. A theoretical investigation of the lateral stability of the helicopter by Hohenemser, although made for a side-by-side twin-rotor helicopter, is in good agreement with the results of this note.

EFFECTS OF AIR HUMIDITY IN SUPERSONIC WIND TUNNELS. Julius Lukasiewicz and J. K. Royle. 1953. 35p. diagrs., photos., 7 tabs. (ARC R & M 2563; ARC 10,977; ARC 12,374. Formerly RAE Aero 2211; SD 20; Tech. Note Aero 1982; SD 89)

The available theoretical and experimental information on condensation of water vapor in the supersonic flow of air is reviewed and the influence of condensation on operation of supersonic tunnels is considered. The mechanism of condensation in supersonic flow is of molecular nature and does not depend on the presence of solid condensation nuclei in the air. As estimated by Oswatitsch and confirmed by experimental results, the condensation in supersonic flow of air is primarily a function of the adiabatic supercooling $\Delta T_{k \text{ to ad}}$ which determines the conditions at which the condensation shock occurs. For medium-sized supersonic tunnels (say 1-foot square working section) the adiabatic supercooling is of the order of 50° C. For most test purposes, it is essential to eliminate the detrimental effects of condensation on flow distribution in the tunnel working section. The usual method is to use highly dried air, and the question of the required dryness is considered. Other methods, which do not rely on the dryness of air, are discussed. It is shown that by increasing stagnation temperature condensation can be avoided usually only at Mach numbers smaller than 1.5. Alternatively, condensation can be eliminated from the tunnel nozzle by pre-expansion in an auxiliary nozzle, as verified experimentally.

SUPERSONIC THEORY FOR OSCILLATING WINGS OF ANY PLAN FORM. W. P. Jones. 1953. 11p. diagrs. (ARC R & M 2655. Formerly ARC 11,559; 0.730; FM 1254)

A theory for thin wings of any plan form describing simple harmonic oscillations of small amplitude in a supersonic airstream is developed. It is based on the use of the generalized Green's Theorem in conjunction with particular solutions which vanish over the characteristic cone with vertex at any point in the field of flow. The theory can be used to calculate the aerodynamic forces acting on fluttering wings when the modes of distortion are known.

FLIGHT TESTS ON SWINGING DURING TAKE-OFF ON A SINGLE-ENGINED FIGHTER-BOMBER (TYPHOON Ib). W. Stewart. 1953. 29p. diagrs., tab. (ARC R & M 2660; ARC 11,725. Formerly RAE Aero 2261)

Values of the aerodynamic side forces and yawing moments during take-off are compared with wind-tunnel measurements. Various methods of estimating the rudder angles required to trim during take-off are compared also. Results show very good agreement with wind-tunnel tests. It was not possible to obtain smooth application of the rudder and records show considerable over-correction by the pilot. This over-correction by the pilot is quite general and as a result some considerable margin of control must be available in excess of that required for trim.

Aeronautical Research Council (Gt. Brit.) CORRECTIONS FOR SYMMETRICAL SWEPT AND TAPERED WINGS IN RECTANGULAR WIND TUNNELS. W. E. A. Acum. 1953. 33p. diagrs., 41 tabs. (ARC R & M 2777. Formerly ARC 13,050; Perf. 649; ARC 14,159; Perf. 815)

In the case of wings with straight leading and trailing edges, the interference upwash due to the images of the wing in the wind-tunnel walls may be determined in terms of three functions of the parameters defining the size of the wing and tunnel. These functions have been tabulated and used to estimate the effect on C_L and C_M, for wings of a variety of sizes and shapes. The variation of mean induced incidence with sweep and taper was found to be small. A formula is given for computing the residual correction to C_M for each special case.

N-28944*

Aeronautical Research Council (Gt. Brit.) THE PRESSURE DISTRIBUTION, AT SUPERSONIC SPEEDS AND ZERO LIFT, ON SOME SWEPT-BACK WINGS HAVING SYMMETRICAL SECTIONS WITH ROUNDED LEADING EDGES. G. M. Roper. 1954. 20p. diagrs. (ARC R & M 2700; ARC 12,364. Formerly RAE Aero 2312)

Formulas are found for the pressure distribution at supersonic speeds and at zero incidence for certain symmetrical surfaces of small finite thickness, with sweptback leading edges. The surfaces are set symmetrically to the wind direction. The solution is only valid if the surfaces lie wholly within the Mach cone of the apex. Solutions are applied to give the pressure distribution for wings of small finite thickness with straight leading edges and a hyperbolic or parabolic trailing edge. Some calculations for wing drag have also been made for sweptback wings.

Aeronautical Research Council (Gt. Brit.) AN APPROXIMATE SOLUTION OF THE COMPRESSIBLE LAMINAR BOUNDARY LAYER ON A FLAT PLATE. R. J. Monaghan. 1953. 24p. diagrs., 2 tabs. (ARC R & M 2760; ARC 12,963. Formerly RAE Tech. Note Aero 2025, sup. 96)

The flat plate problem has received the attention of many workers, but as yet all solutions have been purely numerical for special cases. In this paper, an approximate, analytical solution is presented which is more general and has the merits of simplicity. The equations are algebraic in form whereas previous results have involved complex numerical integrations for individual cases. The solution given shows clearly the effects of changes in working conditions.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) FLIGHT TESTS OF A YOUNGMAN-HUGHES STALL WARNING DEVICE ON A NENE VIKING AIRCRAFT. D. A. Lang. November 23, 1953. 22p. diagrs., 4 tabs. (AAEE/Inst/91)

A Youngman-Hughes stall warning device was tested on a Nene Viking. The device depends for operation on the changes in pressure distribution around the lower surface of the leading edge of the wing as the stall is approached. The installation operated satisfactorily. Though it was tested on the Nene Viking, the device should be applicable to other aircraft. It should give suitable warning of the low altitude, slow speed stall, that is for the condition where adequate warning is imperative.

RECORDED PRESSURE DISTRIBUTION IN THE OUTER PORTION OF A TORNADO VORTEX. William Lewis and Porter J. Perkins. (Reprint from Monthly Weather Review, v. 81, no. 12, December 1953, p. 379-385)

This tornado took place on June 8, 1953 and passed through a portion of the Lewis Flight Propulsion Laboratory. Eight barographs were in operation at various locations within the laboratory at the time. Records are presented from nine barographs located in a small area close to the path of a tornado. The pressure profile in the range from 720 to 2,300 feet from the path of the tornado center as determined from the barograph records was found to be in good agreement with calculations based on a simple model consisting of a frictionless vortex with in-flow.

HEAT CONDUCTION IN LAMINATED SPHERICAL AND CYLINDRICAL BODIES. (Wärmeleitung in geschichteten kugel- und zylinderkörpern). V. Vodicka. 24p. (Trans. from Schweizer Archiv, Annales Suisses, v. 16, no. 10, October 1950, p. 297-304).

The problem of unsteady heat flow within spherical and cylindrical bodies each consisting of an indefinite number of concentric spherical or cylindrical laminae is solved. The postulated conditions are: that the successive laminae are in perfect thermal contact; that the innermost surface (which may have a zero radius) is impermeable to heat; that a fixed, finite heat-transfer coefficient exists at the outer surface; and that an arbitrary known temperature distribution exists in the body initially. All of the necessary mathematical relations are worked out, including relations required to determine the coefficients appearing in the solution equations, but no numerical examples are given.

VORTEX FLOW IN AXIAL MACHINES. (Écoulements tourbillonnaires dans les machines axiales). R. Siestrunck and J. Fabri. 83p. diagrs. (Trans. from Office National d'Études et de Recherches Aéronautiques. Pub. 45).

Properties of rotational motion in axial machines and of an incompressible fluid in a cylindrical duct are discussed. The stream function describing the evolution of the fluid motion is used systematically. The Prandtl reduction of the blades to lifting lines is retained. Several linearized solutions for a compressible fluid are given which show that the general equations for incompressible flow, linearized, do not lead to inextricable calculations. Examples given are for cylindrical and convergent ducts.

AERODYNAMIC CHARACTERISTICS OF NACA RM-10 MISSILE IN 8- BY 6-FOOT SUPERSONIC WIND TUNNEL AT MACH NUMBERS FROM 1.49 TO 1.98. I - PRESENTATION AND ANALYSIS OF PRESSURE MEASUREMENTS (STABILIZING FINS REMOVED). Roger W. Luidens and Paul C. Simon. July 20, 1950. 53p. diagrs., photos. (NACA RM E50D10) (Declassified from Confidential, 3/10/54)

Experimental investigation of flow about a slender body of revolution (NACA RM-10 missile) alined and inclined to a supersonic stream was conducted at Mach numbers from 1.49 to 1.98 at a Reynolds number of approximately 30,000,000. Boundary-layer measurements at zero angle of attack are correlated with subsonic formulations for predicting boundary-layer thickness and profile. Comparison of pressure coefficients predicted by theory with experimental values showed close agreement at zero angle of attack and angle of attack except over the aft leeward side of body. At angle of attack, pitot pressure measurements in plane of model base indicated a pair of symmetrically disposed vortices on leeward side of body.

A FINITE-STEP METHOD FOR THE CALCULATION OF SPAN LOADINGS OF UNUSUAL PLAN FORMS. George S. Campbell. July 16, 1951. 34p. diagrs., 4 tabs. (NACA RM L50L13) (Declassified from Confidential, 3/10/54)

The applicability of a finite-step method to the calculation of subsonic spanwise load distribution, lift-curve slope, lateral center of pressure, and aerodynamic center of unusual plan forms has been investigated. Computing forms are presented to simplify calculation of span loadings for conventional swept, M plan-form, and W plan-form wings. Tables of the downwash in the plane of a yawed vortex are presented. Span loadings have been compared with those obtained by Falkner and Weissinger for several plan forms. The effect of an extra vortex located near the tip, the use of yawed vortices, and the number of steps necessary are discussed in the light of calculated results.

CURRENT NACA REPORTS

NACA Rept. 1131

DEFLECTION AND STRESS ANALYSIS OF THIN SOLID WINGS OF ARBITRARY PLAN FORM WITH PARTICULAR REFERENCE TO DELTA WINGS. Manuel Stein, J. Edward Anderson and John M. Hedgepeth. 1953. ii, 20p. diagrs., photo. (NACA Rept. 1131. Formerly TN 2621)

The structural analysis of arbitrary solid cantilever wings by small-deflection thin-plate theory is reduced to the solution of linear ordinary differential equations by the assumption that the chordwise deflections at any spanwise station may be expressed in the form of a power series in which the coefficients are functions of the spanwise coordinate. Experimental deflection and stress data for constant-thickness delta-plate specimens of 45° and 60° sweep are presented and are found to compare favorably with the present theory.

NACA Rept. 1137

INITIAL RESULTS OF INSTRUMENT-FLYING TRIALS CONDUCTED IN A SINGLE-ROTOR HELICOPTER. Almer D. Crim, John P. Reeder and James B. Whitten. 1953. ii, 7p., diagrs., photos. (NACA Rept. 1137. Formerly TN 2721.)

Instrument-flying trials were conducted in a single-rotor helicopter, the maneuver stability of which could be changed from satisfactory to unsatisfactory. Results indicated that existing longitudinal flying-qualities requirements based on contact flight were adequate for instrument flight at speeds above that for minimum power. Lateral-directional problems were encountered at low speeds. The conclusion was reached that special helicopter instruments would be desirable under all conditions and necessary for sustained low-speed instrument flight.

NACA Rept. 1138

STUDY OF INADVERTENT SPEED INCREASES IN TRANSPORT OPERATION. Henry A. Pearson. 1953. ii, 11p. diagrs., tab. (NACA Rept. 1138. Formerly TN 2638)

Factors relating to inadvertent speed and Mach number increases in transport operation are discussed with the object of indicating the manner in which they might vary with different qualities of the airplane and the minimum margins required to guard against reaching unsafe values. Speed increments and the margins required under several assumed conditions are investigated. Results indicate that smaller margins should be required of high-speed airplanes than of low-speed airplanes to prevent overspeeding in inadvertent maneuvers. The possibility of exceeding placard speed in prolonged descents is illustrated by computations for typical transport airplanes. Equations are suggested that allow estimates to be made of the necessary speed margins.

NACA Rept. 1147

THE SIMILARITY LAW FOR HYPERSONIC FLOW AND REQUIREMENTS FOR DYNAMIC SIMILARITY OF RELATED BODIES IN FREE FLIGHT. Frank M. Hamaker, Stanford E. Neice and Thomas J. Wong. 1953. ii, 11p. diagrs. (NACA Rept. 1147. Formerly TN 2443; TN 2631)

The similarity law for nonsteady, inviscid, hypersonic flow about slender three-dimensional shapes is derived. Conclusions drawn are shown to be valid for rotational flow. Requirements for dynamic similarity of related shapes in free flight are obtained. The law is examined for steady flow about related three-dimensional shapes. Results of an experimental investigation of the pressures acting on two inclined cones are found to check the law as it applies to bodies of revolution.

NACA RM E53L31a

INVESTIGATION OF EFFECT OF NOTCHES ON ELEVATED-TEMPERATURE FATIGUE STRENGTH OF N-155 ALLOY. C. A. Hoffman. April 1954. 8p. diagrs., tab. (NACA RM E53L31a)

An investigation of the effect of notches on the fatigue strength of N-155 alloy at elevated temperatures was conducted by the NACA in cooperation with the Gas Turbine Panel of the joint A.S.T.M.-A.S.M.E. Committee on Effects of Temperature on the Properties of Metals. Studies were made at 1350° and 1500° F in completely reversed bending. The results on relatively few specimens indicated that: (a) Notches reduced fatigue strength at 1350° F by approximately 34 to 40 percent and at 1500° F by approximately 30 to 37 percent over the range of 3 to 150 hours, and (b) the notch sensitivity in fatigue under conditions of completely reversed bending at 1350° and 1500° F was considerably less than that predicted for static bending under elastic conditions.

NACA TN 3076

LIFT AND MOMENT COEFFICIENTS EXPANDED TO THE SEVENTH POWER OF FREQUENCY FOR OSCILLATING RECTANGULAR WINGS IN SUPERSONIC FLOW AND APPLIED TO A SPECIFIC FLUTTER PROBLEM. Herbert C. Nelson, Ruby A. Rainey and Charles E. Watkins. April 1954. 53p. diagrs. (NACA TN 3076)

Linearized theory for compressible unsteady flow is used to derive the velocity potential and lift and moment coefficients in the form of power series in terms of the frequency of oscillation for a harmonically oscillating rectangular wing moving at a constant supersonic speed. Closed expressions for the velocity potential and lift and moment coefficients associated with pitching and translation are given to the seventh power of the frequency. These expressions extend the range of usefulness of NACA Report 1028 in which similar expressions were derived to the third power of the frequency of oscillation. The section and total lift and moment coefficients are discussed with the aid of several figures. In addition, flutter speeds obtained in the Mach number range from 10/9 to 10/6 for a rectangular wing of aspect ratio 4.53 by using section coefficients derived on the basis of three-dimensional flow are compared with flutter speeds for this wing obtained by using coefficients derived on the basis of two-dimensional flow.

NACA TN 3078

TRANSIENT TEMPERATURES IN HEAT EXCHANGERS FOR SUPERSONIC BLOWDOWN TUNNELS. Joseph H. Judd. April 1954. 35p. diagrs., 2 tabs. (NACA TN 3078)

A method has been presented for the computation of tube and fluid temperatures for fluid flowing through heat exchangers of the heat-accumulator type in which the temperatures are low enough so that radiation may be neglected. Three entrance air conditions were considered, constant temperature, exponentially decreasing temperature, and linearly decreasing temperature. Agreement was found between experimental and computed tube and air temperatures for inlet air at constant temperature and at atmospheric pressure.

NACA TN 3084

A METHOD FOR MEASURING THE PRODUCT OF INERTIA AND THE INCLINATION OF THE PRINCIPAL LONGITUDINAL AXIS OF INERTIA OF AN AIRPLANE. Robert W. Boucher, Drexel A. Rich, Harold L. Crane and Cloyce E. Matheny. April 1954. 39p. diagrs., photos., 6 tabs. (NACA TN 3084)

An analysis has been made of a method for experimentally determining the moments of inertia and the product of inertia about the body reference axes, the moments of inertia about the principal axes, and the inclination of the principal longitudinal axis. The results of the application of this method and the associated equipment and techniques are discussed for both a simple model and a conventional airplane.

NACA TN 3085

AN EXPERIMENTAL STUDY OF POROSITY CHARACTERISTICS OF PERFORATED MATERIALS IN NORMAL AND PARALLEL FLOW. George M. Stokes, Don D. Davis, Jr. and Thomas B. Sellers. April 1954. 24p. diagrs., photos. (NACA TN 3085. Formerly RM L53H07)

Experimental data have been obtained to show some of the flow characteristics of perforated materials when subjected to airstreams directed normal and parallel to the surface of the material. The results of these tests showed that the effective porosity of the material dropped markedly as the stream velocity increased. The most important parameter for determining the discharge coefficients of the perforated material was the ratio of the stream velocity to the free jet velocity.

NACA TN 3110

TRENDS OF ROLLING-CONTACT BEARINGS AS APPLIED TO AIRCRAFT GAS-TURBINE ENGINES. (Papers presented at the SAE Summer Meeting, Atlantic City, N.J., 1952). Panel on High-Speed Rolling-Contact Bearings. Appendix A. PROBLEMS PERTAINING TO HIGH-SPEED ROLLING-CONTACT AIRCRAFT BEARINGS OF CONCERN TO THE BEARING INDUSTRY. Daniel Gurney, Marlin-Rockwell Corp. Appendix B. PROBLEMS PERTAINING TO HIGH-SPEED ROLLING-CONTACT BEARINGS IN AIRCRAFT TURBINE ENGINES OF CONCERN TO THE MILITARY. C. M. Michaels, Wright Air Development Center. Appendix C. ROLLING-CONTACT BEARINGS AS APPLIED TO AIRCRAFT GAS TURBINES FROM THE ENGINE MANUFACTURER'S POINT OF VIEW. Stephen Drabek, General Electric Co. Appendix D. NEW DEVELOPMENTS IN HIGH-SPEED ROLLING-CONTACT BEARINGS. Frank W. Wellons, SKF Industries, Inc. Appendix E. BASIC FRICTION AND WEAR STUDIES OF ROLLING-CONTACT-BEARING CAGE MATERIALS. Robert L. Johnson, Max A. Swikert and Edmond E. Bisson. Appendix F. PRESENT STATUS OF RESEARCH KNOWLEDGE IN THE FIELD OF HIGH-SPEED ROLLING-CONTACT BEARINGS. E. F. Macks. April 1954. (ii), 62p. diagrs., photos. (NACA TN 3110)

Requirements for rolling contact bearings for future aircraft gas-turbine engines are severe. Operating temperatures to 750° F, thrust loads to 50,000 pounds, and DN values to 3.5×10^6 are desired. Cage material compatibility, bearing endurance life, high-temperature lubricants, and lubricant cooling are expected to be the major problems. These and related problems are discussed from the viewpoints of the bearing industry, engine manufacturers, and the military. Some recent research results are given, and the need for further research on an expanded scale is emphasized.

NACA TN 3128

COMPARISON BETWEEN THEORY AND EXPERIMENT FOR INTERFERENCE PRESSURE FIELD BETWEEN WING AND BODY AT SUPERSONIC SPEEDS. William C. Pitts, Jack N. Nielsen and Maurice P. Gionfriddo. April 1954. 64p. diagrs., 2 tabs. (NACA TN 3128)

Pressure-distribution data were obtained for a wing-body combination at Mach numbers 1.48 and 2.00 and at Reynolds numbers 0.6, 1.2, and 1.5 x 10^6. The model was a single-wedge, rectangular wing mounted on a cylindrical body with an ogival nose. The body angle of attack ranged between $+6^o$ and -6° and the wing-incidence angle ranged from 0° to -5.7^o. The experimental pressure-distribution and span-loading results are compared with the linear, wing-body interference theory of NACA TN 2677.

NACA TN 3146

NOTE ON THE AERODYNAMIC HEATING OF AN OSCILLATING SURFACE. Simon Ostrach. April 1954. 12p. (NACA TN 3146)

An analysis of the temperature distributions in a fluid over an oscillating surface with heat transfer is made and associated heat-transfer parameters are compared with those for the case of conduction at a stationary surface with the same initial temperature potential. It is found that the heat transfer for the oscillating surface can be considerably different from that for conduction alone. The effect of the surface oscillations on the thermal state of the fluid is studied by means of average static- or total-temperature defects, and it is demonstrated that the oscillations could alter the fluid temperature appreciably.

NACA TN 3165

PRELIMINARY INVESTIGATION OF THE EFFECTS OF HEAT TRANSFER ON BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. April 1954. 23p. diagrs., photos., tab. (NACA TN 3165. Formerly RM L52E29a)

This paper presents the results of a preliminary investigation of the effects of heat transfer on boundary layer transition on a parabolic body of revolution (NACA RM-10) at Mach number of 1.61. This paper includes also a study of the effectiveness of cooling on boundary-layer transition with model surface roughened and a comparison of the results obtained in this investigation with other available theoretical and experimental data.

NACA TN 3166

AN EXTENSION OF THE INVESTIGATION OF THE EFFECTS OF HEAT TRANSFER ON BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. April 1954. 21p. diagrs., photo. (NACA TN 3166. Formerly NACA RM L53B25)

This paper covers the extension of a previous investigation of the effects of heat transfer on boundary-layer transition to higher Reynolds numbers, to greater amounts of heating, and to a more extensive study of the effects of surface roughness and wind-tunnel flow disturbances. The tests were made at a Mach number of 1.6 and over a Reynolds number range from 2.5 x 10^6 to 35 x 10^6. A comparison is made between the experimental results and theory.

NACA TN 3170

AN EXPERIMENTAL INVESTIGATION AT LOW SPEEDS OF THE EFFECTS OF LIP SHAPE ON THE DRAG AND PRESSURE RECOVERY OF A NOSE INLET IN A BODY OF REVOLUTION. James R. Blackaby and Earl C. Watson. April 1954. 48p. diagrs., photos. (NACA TN 3170)

A low-speed investigation, for an angle of attack and angle of yaw of 0°, was made of the effects of inlet lip bluntness and profile on the performance of a ducted body of revolution. A sharp inlet lip profile was tested in addition to five circular-arc profiles having contraction ratios (ratio of area at inlet leading edge to minimum inlet area) of about 1.04, 1.08, 1.16, 1.24, and 1.33, and two lips with elliptical internal profiles and approximately elliptical external profiles having contraction ratios of about 1.08 and 1.18.

NACA TN 3172

EFFECTS OF LEADING-EDGE RADIUS AND MAXIMUM THICKNESS-CHORD RATIO ON THE VARIATION WITH MACH NUMBER OF THE AERODYNAMIC CHARACTERISTICS OF SEVERAL THIN NACA AIRFOIL SECTIONS. Robert E. Berggren and Donald J. Graham. April 1954. 65p. diagrs., 7 tabs. (NACA TN 3172. Formerly RM A50D04)

The results of a wind-tunnel investigation at Mach numbers to approximately 0.9 and Reynolds numbers from 1 x 10^6 to 2 x 10^6 indicate no significant effects of leading-edge-radius variation on the variation with Mach number of the aerodynamic characteristics of 4- and 6-percent-chord-thick NACA 4-digit-series airfoil sections. The results indicate beneficial effects of maximum thickness reduction on lift and drag characteristics and no important effects on moment characteristics.

SURFACE DEFECTS IN VENEERING. R. J. Newall, Forest Products Laboratory. (Reprint from Wood, v. 18, December 1953, p. 462-465)

Examination of defective veneering shows that there are two main types of defect: (1) checking or cracking of the veneered surface and (2) shallow furrows in the surface. These defects are discussed in detail and suggestions are made for their elimination. It is indicated that the cause of the defects is that the moisture content of the base material might be too high when the veneer is applied.

National Gas Turbine Establishment (Gt. Brit.) A CORRELATION OF THE PERFORMANCE OF TWO AIR BLAST ATOMISERS WITH MIXING SECTIONS OF DIFFERENT SIZE. A. Radcliffe and H. Clare. October 1953. 39p. diagrs., tab. (NGTE R. 144)

The work on the N.G.T.E. air blast atomizer has been extended and the effect of increasing the orifice diameter has been examined. It is shown that the main factor controlling atomization is the air:fuel ratio and that when this is 0.1 the Sauter mean diameter is about 100 microns. This is for fuel of viscosity 20 to 40 centistokes. The droplet size increases approximately as the square root of the linear dimensions of the orifice and mixing section.

CALCULATED PRESSURE, AREA AND IMPULSE RATIOS FOR SUPER-CRITICAL EXPANSION OF COMBUSTION GASES. A. B. P. Beeton. November 1953. 31p. diagrs., 3 tabs. (NGTE R. 145)

Expansion conditions beyond the throat of convergent-divergent exit nozzles are studied. Assuming isentropic flow, theoretical values have been calculated relating the flow area, impulse and pressure for combustion gases expanded down to supercritical pressure ratios. The results are expressed in the form of two master curves which apply to 20:1 air/fuel ratio, 450° K initial air temperature and 1 atmosphere total pressure. Additional curves are given to derive an additive correction for any air/fuel ratio between 10:1 and 50:1. The range covered is from the throat down to about 12:1 pressure ratio.

THE FATIGUE PROPERTIES OF INVESTMENT-CAST 0.2 PER CENT CARBON, 18 PER CENT CHROMIUM, 2 PER CENT NICKEL STAINLESS STEEL AND THEIR IMPROVEMENT BY NITRIDING AND SHOT-PEENING. T. Fitzgerald and J. E. Northwood. October 1953. 46p. diagrs., photos., 6 tabs. (NGTE Memo. M. 162)

Low fatigue properties have been obtained with the 0.2-percent carbon, 18-percent chromium, 2-percent nickel stainless steel in the investment cast and heat treated condition. Attempts have been made to improve its fatigue strength by processes which increase the endurance ratio, without any serious effect on tensile properties and ductility. Fatigue tests have shown that nitriding or shot-peening can be used to increase the fatigue strength of investment cast blades to a level on a par with that of the wrought material. The increase in fatigue strength brought about by either of these processes was partly controlled by the condition of the metal surface prior to treatment, increases in fatigue strength of up to 40 percent above that of the "as cast" surface condition being obtained by nitriding or peening the surfaces of buffed or electrolytically polished blades and test pieces.

LIQUID MANOMETERS WITH HIGH SENSITIVITY AND SMALL TIME-LAG. F. A. MacMillan. August 14, 1953. 14p. diagrs., photos. (ARC 16,091; TP 404; FM 1941)

For some purposes a sensitive manometer is required having a small time lag when connected to a small bore tube or orifice. The time lag which can be tolerated is limited by the rate of change of the zero reading. Some problems in the design of a manometer with small time lag and small rate of change of zero reading are discussed, and some general principles of design are derived. It is shown that with a null-reading inclined-tube manometer, changes of zero reading due to variation of temperature can be eliminated by correct choice of the manometer dimensions. A manometer designed according to the principles derived is described; this has a small time lag, a range of 2.5 cm of liquid, and a sensitivity of 0.0005 cm of liquid.

NACA RM L8J06

NACA TRANSONIC WIND-TUNNEL TEST SECTIONS. Ray H. Wright and Vernon G. Ward. October 25, 1948. 93p. diagrs., photos., 3 tabs. (NACA RM L8J06) (Declassified from Confidential, 3/10/54)

An approximate subsonic theory has been developed for the solid blockage in a circular wind tunnel with walls slotted in the direction of flow. In tests of a tunnel based on this theory, a prediction of the theory regarding the possibility of practical elimination of the interference due to solid blockage has been realized. Choking limitations did not occur in the slotted tunnel, and it could be operated with continuous Mach number variation up to low supersonic Mach numbers merely by varying the power. Pressure distributions over the surface of a nonlifting model in the slotted tunnel were compared with those obtained over the same model in a much larger tunnel where the interference was negligible.

NACA RM L9D18

PRELIMINARY INVESTIGATION OF 3-INCH SLOTTED TRANSONIC WIND-TUNNEL TEST SECTIONS. George P. Bates. September 9, 1949. 18p. diagrs. (NACA RM L9D18) (Declassified from Confidential, 3/10/54)

An investigation has been made on two slotted test sections in a 3-inch circular blowdown apparatus to determine the characteristics of slotted throats for transonic and supersonic operation. One of the sections investigated had 20 slots, with 1/5-open wall area, while the other section had 8 slots and was 1/8 open.

NACA RM L9D29a

PRELIMINARY INVESTIGATION OF A VARIABLE MACH NUMBER TWO-DIMENSIONAL SUPERSONIC TUNNEL OF FIXED GEOMETRY. William J. Nelson and Frederick Bloetscher. June 9, 1949. 54p. diagrs., photos. (NACA RM L9D29a) (Declassified from Confidential, 3/10/54)

Variable Mach number supersonic flows have been generated in a 2-1/4 by 4-1/2 inch fixed-geometry rectangular channel by removal of air through longitudinal slots of several profiles and proportions. The nature of the flow over a range of Mach numbers up to 1.45 is shown in schlieren photographs and pressure distributions along the channel. The most uniform flow was produced by removal of air through a single slot in a flat surface.

NACA RM L50B01

PRELIMINARY INVESTIGATION OF CONSTANT-GEOMETRY, VARIABLE MACH NUMBER, SUPERSONIC TUNNEL WITH POROUS WALLS. William J. Nelson and Paul L. Klevatt. May 3, 1950. 27p. diagrs., photos. (NACA RM L50B01) (Declassified from Confidential, 3/10/54)

A method of generating variable Mach number supersonic flow in a channel of fixed geometry by the removal of air through uniform porous walls is discussed. Calculated porosity distributions are presented for several minimum-length nozzles designed to operate at Mach numbers up to 2.0. The axial pressure gradient has been calculated for several constant-porosity walls over a range of Mach numbers. The applicability of these calculations to a two-dimensional tunnel is illustrated by comparison of calculated and experimentally determined pressure gradients in the 2-1/4 by 4-1/2 inch channel at Mach numbers in the range covered in the present tests, 0.99 to 1.17. Schlieren photographs of the flow in the experimental channel are also presented.

NACA RM L50D27

PRELIMINARY INVESTIGATION OF POROUS WALLS AS A MEANS OF REDUCING TUNNEL BOUNDARY EFFECTS AT LOW-SUPERSONIC MACH NUMBERS. William J. Nelson and Frederick Bloetscher. September 13, 1950. 21p. diagrs., photos. (NACA RM L50D27) (Declassified from Confidential, 3/10/54)

The use of porous-walled tunnels at supersonic Mach numbers as a means of avoiding reflection of stream disturbance extending to the walls is discussed. Calculated shock-reflection characteristics of porous materials are presented in the form of design charts for Mach numbers up to 1.5 and incident shock deviations up to 6°. Shocks reflected from sintered-bronze and bonded-screen walls at a Mach number of 1.2 are consistent with the calculated reflections.

NACA RM L50G19a

PRELIMINARY INVESTIGATION OF REFLECTIONS OF OBLIQUE WAVES FROM A POROUS WALL. Don D. Davis, Jr. and George P. Wood. November 9, 1950. 33p. diagrs., photos. (NACA RM L50G19a) (Declassified from Confidential, 3/10/54)

A porous wall was used in an attempt to eliminate reflections of oblique waves from a tunnel wall. Calculations were made of the required resistance characteristics of a wall in order that the flow through the wall, due to the pressure difference across a shock wave, would equal the component normal to the wall of the flow behind the shock wave. The resistance characteristic of a sintered-bronze wall was measured and the reflections of waves impinging on the wall were observed at a Mach number of 1.62. The intensity of the reflections was greatly reduced by permitting flow through the wall.

NACA RM L51F14

COMPARISON OF TRANSONIC CHARACTERISTICS OF LIFTING WINGS FROM EXPERIMENTS IN A SMALL SLOTTED TUNNEL AND THE LANGLEY HIGH-SPEED 7- BY 10-FOOT TUNNEL. William C. Sleeman, Jr., Paul L. Klevatt and Edward L. Linsley. November 5, 1951. 44p. diagrs., photos. (NACA RM L51F14) (Declassified from Confidential, 3/10/54)

A comparison is made of the transonic aerodynamic characteristics of two unswept and two 45° swept-back wings tested in a 4.5- by 6.25-inch slotted tunnel over a Mach number range from 0.70 to 1.30 and the Langley high-speed 7- by 10-foot tunnel side-wall reflection plane up to $M = 1.08$. Two geometrically similar wings having a semispan of 4.24 and 2.55 inches for both sweep angles were tested to investigate effects of model size in the slotted tunnel. Two slot areas, 1/8 and 1/5 of the horizontal boundaries open, were used in the tests.

NACA RM L52C18

AN EXPERIMENTAL INVESTIGATION OF THE ZERO-LIFT PRESSURE DISTRIBUTION OVER A WEDGE AIRFOIL IN CLOSED, SLOTTED, AND OPEN-THROAT TUNNELS AT TRANSONIC MACH NUMBERS. William J. Nelson and Frederick Bloetscher. June 16, 1952. 34p. diagrs., photos. (NACA RM L52C18) (Declassified from Confidential, 3/10/54)

Pressure distributions and schlieren photographs of the flow about a 10-percent-thick diamond airfoil at zero lift in two-dimensional closed, slotted, and open-throat tunnels are presented and discussed. Uncorrected airfoil pressures obtained in 1/5- and 1/8-open slotted throat tunnels are compared at subsonic Mach numbers with corrected results from open and closed test sections of the same dimensions. The effect of varying the slot width has been investigated at Mach numbers up to 0.92. At Mach numbers up to 1.18, data obtained in test sections whose upper and lower boundaries were slotted to provide openings the combined width of which was equal to 1/8 of the tunnel width are shown to be consistent with theory and available experiments.

NACA RM L52E27

REFLECTION OF SHOCK WAVES FROM SLOTTED WALLS AT MACH NUMBER 1.62. George P. Wood. July 21, 1952. 16p. diagrs., photos. (NACA RM L52E27) (Declassified from Confidential, 3/10/54)

A brief study was made of the effect of slots in a test-section wall on the reflection from the wall of an incident oblique shock wave at a free-stream Mach number of 1.62. The reflection was observed with an interferometer for various combinations of slot width, spacing, and contour. The reflections from the open and closed portions of the wall, being at different angles to the wall, were not superposed and, therefore, did not cancel each other.

NACA RM L53A26

THEORETICAL STUDY OF THE TUNNEL-BOUNDARY LIFT INTERFERENCE DUE TO SLOTTED WALLS IN THE PRESENCE OF THE TRAILING-VORTEX SYSTEM OF A LIFTING MODEL. Clarence W. Matthews. April 7, 1953. 56p. diagrs. (NACA RM L53A26) (Declassified from Confidential, 3/10/54)

The equations which represent the interference on the lift of uniformly loaded wings of finite span in circular tunnels with mixed open and closed boundaries are derived, with special attention to those tunnels containing symmetrical arrangements of the open and closed portions. The equations are applicable to tunnels with other cross-sectional shapes, provided a transformation function can be found which will transform the tunnel cross section into a circle.

NACA RM L53E07b

ANALYTICAL STUDY OF BLOCKAGE- AND LIFT-INTERFERENCE CORRECTIONS FOR SLOTTED TUNNELS OBTAINED BY THE SUBSTITUTION OF AN EQUIVALENT HOMOGENEOUS BOUNDARY FOR THE DISCRETE SLOTS. Don D. Davis, Jr. and Dewey Moore. June 29, 1953. 57p. diagrs. (NACA RM L53E07b) (Declassified from Confidential, 3/10/54)

Numerical results are presented for the boundary interference on lifting wings and for the solid-blockage interference for a doublet on the tunnel axis in circular, rectangular, and two-dimensional slotted tunnels. In the analysis, an equivalent homogeneous wall has been substituted for the physical boundary of discrete slots. The results are found to be consistent with those calculated for the discrete slots and with available experimental results.

NACA RM A53E29

WALL INTERFERENCE IN WIND TUNNELS WITH SLOTTED AND POROUS BOUNDARIES AT SUBSONIC SPEEDS. Barrett S. Baldwin, Jr., John B. Turner and Earl D. Knechtel. October 9, 1953. 42p. diagrs. (NACA RM A53E29) (Declassified from Confidential, 3/10/54)

Linearized compressible-flow analysis is applied to the study of wind-tunnel-wall interference for subsonic flow in either two-dimensional or circular test sections having slotted or porous walls. Expressions are developed for evaluating blockage and lift interference.

CURRENT NACA REPORTS

NACA Rept. 1125

DYNAMICS OF MECHANICAL FEEDBACK-TYPE HYDRAULIC SERVOMOTORS UNDER INERTIA LOADS. Harold Gold, Edward W. Otto and Victor L. Ransom. 1953. ii, 21p. diagrs., photos. (NACA Rept. 1125. Formerly TN 2767)

An analysis of the dynamics of mechanical feedback-type hydraulic servomotors under inertia loads is developed and experimental verification is presented. This analysis, which is developed in terms of two physical parameters, yields direct expressions for the following dynamic responses: (1) the transient response to a step input and the maximum cylinder pressure during the transient and (2) the variation of amplitude attenuation and phase shift with the frequency of sinusoidally varying input. Close agreement was obtained between analytically determined responses and measured responses.

NACA Rept. 1128

CALCULATIONS ON THE FORCES AND MOMENTS FOR AN OSCILLATING WING-AILERON COMBINATION IN TWO-DIMENSIONAL POTENTIAL FLOW AT SONIC SPEED. Herbert C. Nelson and Julian H. Berman. 1953. ii, 16p. diagrs., 2 tabs. (NACA Rept. 1128. Formerly TN 2590)

The linearized theory for compressible unsteady flow is used, as suggested in recent contributions to the subject, to obtain the velocity potential and the lift and moment for a thin, harmonically oscillating, two-dimensional wing-aileron combination moving at sonic speed. The velocity potential is derived by considering the sonic case as the limit of the linearized supersonic theory. The paper provides extensive tables of numerical values for the coefficients contained in the expressions for lift and moment, for various values of the reduced frequency $k(0 < k \leq 3.5)$ and aileron hinge position (from 10 to 90 percent of the wing chord).

NACA Rept. 1129

TRANSVERSE VIBRATIONS OF HOLLOW THIN-WALLED CYLINDRICAL BEAMS. Bernard Budiansky and Edwin T. Kruszewski. 1953. ii, 10p. diagrs. (NACA Rept. 1129. Formerly TN 2682)

The variational principle, differential equations, and boundary conditions considered appropriate to the analysis of transverse vibrations of hollow cylindrical beams are shown. General solutions for the modes and frequencies of cantilever and free cylindrical beams of arbitrary cross section but of uniform thickness are given. The combined influence of the secondary effects of transverse shear deformation, shear lag, and longitudinal inertia is shown in the form of curves for cylinders of rectangular cross section and uniform thickness. The contribution of each of the secondary effects to the total reduction in the actual frequency is also indicated.

NACA RM E54B08

APPLICATION OF PULSE TECHNIQUES TO STRAIN GAGES. Newell D. Sanders and George H. Brodie. May 1954. 17p. diagrs. (NACA RM E54B08)

Pulse techniques have been applied to strain gages for increasing the output level and extending the usable range. Bonded and unbonded strain gages which normally operate with exciting potentials between 3.5 and 14 volts were operated satisfactorily with 200-volt pulses of 1-microsecond duration and a repetition rate of 350 per second. Outputs 15 times greater than normal outputs were measured. A pulse-generating circuit and a pulse-detecting circuit are described. An analysis of pulsed operation of strain gages is given.

NACA RM E54B15

EFFECTS OF SOME METAL ADDITIONS ON PROPERTIES OF MOLYBDENUM DISILICIDE. H. A. DeVincentis and W. E. Russell. May 1954. 22p. diagrs., photos., 6 tabs. (NACA RM E54B15)

The effect of the addition of approximately 6 percent nickel, cobalt, or platinum on some properties of molybdenum disilicide was investigated. These additions resulted in appreciably lowering the modulus-of-rupture strength from that of unalloyed molybdenum disilicide. The thermal shock resistance was unimproved. The resistance to oxidation was decreased at higher temperatures. It is believed that above 2000° and 2400° F the nickel and cobalt alloys, respectively, formed low-melting intermetallics and possibly eutectics between these intermetallics. This resulted in considerable porosity. No uncombined metal could be detected in either hot-pressed or heat-treated material. In the platinum-containing bodies, uncombined metal was detected after hot pressing. The concentration of uncombined metal decreased as a result of heat treatment, and after treatment at the higher temperatures, could not be detected.

NACA RM E54B19

VARIATION OF SPONTANEOUS IGNITION DELAYS WITH TEMPERATURE AND COMPOSITION FOR PROPANE-OXYGEN-NITROGEN MIXTURES AT ATMOSPHERIC PRESSURE. Joseph L. Jackson and Richard S. Brokaw. May 1954. 29p. diagrs., 4 tabs. (NACA RM E54B19)

The ignition delays of propane-oxygen-nitrogen mixtures as a function of temperature and composition have been determined in a flow system. The variation of the ignition lag τ at constant temperature can be represented by the equation

$$1/\tau = k\left[C_3H_8\right]\left[O_2\right]^{1/4}$$

where k is a constant. The temperature dependence of this equation over the range investigated (525° to 740° C) is given within 30 percent by the empirical equation:

$$\tau\left[C_3H_8\right]\left[O_2\right]^{1/4} = 0.030 + 5.4 \times 10^{-9}\, e^{14,500/T}$$

with concentrations expressed as mole fractions and temperature as degrees Kelvin.

NACA RM E54C05

EFFECT OF CHANNEL GEOMETRY ON THE QUENCHING OF LAMINAR FLAMES. A. L. Berlad and A. E. Potter, Jr. May 1954. 32p. diagrs., tab. (NACA RM E54C05)

The effect of channel geometry on flame quenching, as calculated on the basis of average active particle chain lengths, is related among six different geometries: plane parallel plates of infinite extent, cylindrical tubes, rectangular slots, cylindrical annuli, and tubes of elliptical and equilaterally triangular shape. Experimental determination of the quenching behavior of propane-air flames over an equivalence-ratio range of 0.82 to 1.30 was made for a series of rectangular slots, cylindrical annuli, and cylindrical tubes in the pressure range 0.08 to 1.0 atmosphere. Ten rectangular-slot geometries covering a length-to-width ratio range of 1:1 to 33.3:1, nine cylindrical annulus geometries covering a diameter-ratio range of 1.33:1 to 25:1, and four cylinder diameters were investigated. Generally good agreement between theory and experiment was found for both rich and lean flames. The average deviation of the predicted quenching distances from the observed ones is 4.3 percent for equivalence ratios less than or equal to unity and 8.6 percent for equivalence ratios greater than unity. These deviations are generally systematic, rather than random. It was also found that relatively small cold surfaces may, when flame immersed, exhibit very large quenching effects.

NACA TN 3067

ROLLING EFFECTIVENESS AND AILERON REVERSAL OF RECTANGULAR WINGS AT SUPERSONIC SPEEDS. John M. Hedgepeth and Robert J. Kell. April 1954. 79p. diagrs., 4 tabs. (NACA TN 3067)

Linearized supersonic lifting-surface theory is used in conjunction with structural influence coefficients to formulate a method for analyzing the aeroelastic behavior in roll at supersonic speeds of a rectangular wing mounted on a cylindrical body. Rolling effectiveness and aileron reversal speed are computed by using a numerical solution which incorporates matrices. Results obtained for an example configuration by using this method are compared with the results obtained by using simplified methods of analysis. For the particular configuration considered, the variation of rolling effectiveness with Mach number is found for two constant-altitude flights.

NACA TN 3086

MANEUVER ACCELERATIONS EXPERIENCED BY FIVE TYPES OF COMMERCIAL TRANSPORT AIRPLANES DURING ROUTINE OPERATIONS. Thomas L. Coleman and Martin R. Copp. April 1954. 26p. diagrs., 3 tabs. (NACA TN 3086)

The magnitude and frequency of occurrence of maneuver accelerations experienced by five types of commercial transport airplanes during routine operations obtained from time-history (VGH) records are presented. The results are compared with available gust-acceleration data for the operations considered.

NACA TN 3141

COMBINED NATURAL- AND FORCED-CONVECTION LAMINAR FLOW AND HEAT TRANSFER OF FLUIDS WITH AND WITHOUT HEAT SOURCES IN CHANNELS WITH LINEARLY VARYING WALL TEMPERATURES. Simon Ostrach. April 1954. 74p. diagrs., 2 tabs. (NACA TN 3141)

The flow of fluids with and without heat sources and subject to body forces between two plane parallel surfaces which are oriented in the direction of the generating body force is analyzed under the condition that the temperature vary linearly along these surfaces. Solutions of this problem are obtained in terms of "universal" functions which are tabulated for simple application to specific cases. Representative velocity and temperature distributions from which detailed study of the heat transfer is made are then computed. It is found that under certain conditions the effects of aerodynamic or frictional heating can be appreciable. Asymptotic solutions (for large values of the Rayleigh number) which render the computations simple are also presented. Comparison of the results from the method given herein with those obtained elsewhere in an approximate manner for a special case simulating the natural-convection flow of fluids with heat sources in a completely enclosed region shows that the approximate method is sufficiently accurate for problems in which the modified Rayleigh number is less than 10^4.

NACA TN 3145

ANALYSIS OF TURBULENT HEAT TRANSFER, MASS TRANSFER, AND FRICTION IN SMOOTH TUBES AT HIGH PRANDTL AND SCHMIDT NUMBERS. Robert G. Deissler. May 1954. 53p. diagrs. (NACA TN 3145)

The expression for eddy diffusivity from a previous analysis was modified in order to account for the effect of kinematic viscosity in reducing the turbulence in the region close to a wall. By using the modified expression, good agreement was obtained between predicted and experimental results for heat and mass transfer at Prandtl and Schmidt numbers between 0.5 and 3000. The effects of length-to-diameter ratio and of variable viscosity were also investigated for a wide range of Prandtl numbers.

NACA TN 3147

IMPINGEMENT OF WATER DROPLETS ON AN ELLIPSOID WITH FINENESS RATIO 10 IN AXISYMMETRIC FLOW. Rinaldo J. Brun and Robert G. Dorsch. May 1954. 37p. diagrs., tab. (NACA TN 3147)

The presence of radomes and instruments that are sensitive to water films or ice formations in the nose section of all-weather aircraft and missiles necessitates a knowledge of the droplet impingement characteristics of bodies of revolution. Because it is possible to approximate many of these bodies with an ellipsoid of revolution, droplet trajectories about an ellipsoid of revolution with a fineness ratio of 10 were computed for incompressible axisymmetric air flow. From the computed droplet trajectories, the following impingement characteristics of the ellipsoid surface were obtained and are presented in terms of dimensionless parameters: (1) total rate of water impingement, (2) extent of droplet impingement zone, and (3) local rate of water impingement. These impingement characteristics are compared briefly with those for an ellipsoid of revolution with a fineness ratio of 5 reported in NACA TN 3099.

NACA TN 3160

A CALCULATION STUDY OF WING-AILERON FLUTTER IN TWO DEGREES OF FREEDOM FOR TWO-DIMENSIONAL SUPERSONIC FLOW. Donald S. Woolston and Vera Huckel. April 1954. 26p. diagrs., tab. (NACA TN 3160)

Results are presented of some sample calculations made for the bending-aileron and torsion-aileron flutter of a wing-aileron system of infinite aspect ratio for several values of Mach number in supersonic flow and also for some subsonic Mach numbers. It is pointed out that the results are subject to various limitations and are not intended to be applicable to a particular configuration. They may serve, however, to provide a preliminary knowledge of the influence of variations in certain parameters and to indicate some of the differences in trends exhibited by the calculations for high speeds and those known to exist for low speeds.

NACA TN 3179

A THEORETICAL INVESTIGATION OF THE HEATING-UP PERIOD OF INJECTED FUEL DROPLETS VAPORIZING IN AIR. M. M. El Wakil, O. A. Uyehara and P. S. Myers, University of Wisconsin. May 1954. 83p. diagrs., tab. (NACA TN 3179)

Theoretical calculations were performed to determine whether the unsteady state, or the time during which the droplet is heating up or cooling down to the wet-bulb temperature, is of importance when single fuel droplets are vaporizing under conditions of interest in jet engines. The calculations were performed for droplets of different size and fuel composition under different ambient air conditions and the results are presented in the form of temperature-, mass-, and penetration-time histories as well as heat and mass transfer histories of single droplets. Experimental apparatus set up in an attempt to verify the importance of the unsteady state is described and a few experimental curves are presented.

NACA TN 3183

MINIMUM-WAVE-DRAG AIRFOIL SECTIONS FOR ARROW WINGS. Morton Cooper and Frederick C. Grant. May 1954. 26p. diagrs., 5 tabs. (NACA TN 3183)

A linearized theoretical analysis has been made to determine minimum-wave-drag airfoil sections for arrow wings at supersonic speeds. The drag was minimized subject to the conditions of either a given thickness ratio at a specified chordwise location or a given volume. Numerical computations were performed for a delta wing and an arrow wing having a ratio of the tangent of the trailing-edge sweep angle to the tangent of the leading-edge sweep angle of 0.4.

NACA TN 3184

BUCKLING OF LONG SQUARE TUBES IN COMBINED COMPRESSION AND TORSION AND COMPARISON WITH FLAT-PLATE BUCKLING THEORIES. Roger W. Peters. May 1954. 15p. diagrs., photo. (NACA TN 3184)

The results of buckling tests of long square tubes loaded in compression, torsion, and combined compression and torsion are compared with theoretical compression and shear buckling curves and with theoretical interaction curves for the buckling of simply supported flat plates. A compression buckling curve previously compared with experiment is again shown to be in good agreement with experimental results; the shear buckling curves derived from compressive stress-strain data by the secant modulus method is in good agreement with experimental results; and theoretical interaction curves previously presented are in good agreement with the results of the combined-load buckling tests. The direction of the loading path is shown to have little or no effect on the shape of the interaction curve.

NACA TN 3189

MINIMUM-DRAG DUCTED AND POINTED BODIES OF REVOLUTION BASED ON LINEARIZED SUPERSONIC THEORY. Hermon M. Parker. May 1954. 30p. diagrs. (NACA TN 3189)

The linearized-drag integral for bodies of revolution at supersonic speeds is presented in a double-integral form which is not based on slender-body approxima-

tions but which reduces to the usual slender-body expression in the proper limit. With the aid of a suitably chosen auxiliary condition, the minimum-external-wave-drag problem is solved for a transition section connecting two semi-infinite cylinders. The projectile tip is a special case and is compared with the Von Kármán projectile tip. Calculations are presented which indicate that the method of analysis gives good first-order results in the moderate supersonic range.

NACA TN 3211

STATISTICAL STUDY OF OVERSTRESSING IN STEEL. G. E. Dieter, G. T. Horne and R. F. Mehl, Carnegie Institute of Technology. April 1954. 34p. diagrs., photos., 7 tabs. (NACA TN 3211)

The effect of overstressing on the fatigue properties of SAE 4340 steel has been studied statistically. In the first part of the study the effect of microstructure on the fatigue damage produced by overstressing was investigated. Fatigue damage was measured by the percentage decrease in fatigue life at the test stress for specimens subjected to varying cycle ratios of fatigue damage at the prestress. The second part of the study was an investigation of the effect of a certain amount of overstressing on the endurance limit and its statistics.

ON THE INFLUENCE OF SINKS ON THE LIFT AND PRESSURE DISTRIBUTION OF AIRFOILS WITH SUCTION SLOTS. F. Ehlers. September 1, 1946. 45p. diagrs., photos. (MAP VG 67; MAP Reports & Translations 189)

The lift and the pressure distribution of an airfoil with suction slots are calculated by the potential theory under special consideration of the trailing-edge suction. The alteration of the lift is shown to be only a function of the sucked-off quantity, if the suction slot is sufficiently distant from the trailing edge; if the suction is applied at the trailing edge, it is moreover dependent on the profile shape, the width of the suction slot, and, to a higher degree, on the angle of incidence. The maximum lift attainable by suction depends on the profile shape according to an estimate. In order to attain higher lift values by trailing-edge suction, it is advantageous to employ thick profiles.

TWO-DIMENSIONAL WIND-TUNNEL INTERFERENCE. L. G. Whitehead. 1954. 15p. diagrs. (ARC R & M 2802. Formerly ARC 13,198; FM 1451)

Exact solutions are given for the inviscid flow past two cylindrical profiles in the center of a stream of limited depth. The first of these relates to a nearly circular cylinder and the second to a thin section giving a constant pressure drop over the greater part of its surface. The stream has either parallel walls, constant pressure walls, or the boundaries may be partly parallel and partly of the constant pressure type. For the thin profiles, the changes of thickness ratio required to give the same pressure distribution as in an unlimited flow are found.

CHEMICAL SOLIDS AS DIFFUSIBLE COATING FILMS FOR VISUAL INDICATIONS OF BOUNDARY-LAYER TRANSITION IN AIR AND WATER. J. D. Main-Smith. 1954. 16p. diagrs., photos., 2 tabs. (ARC R & M 2755; ARC 13,115. Formerly RAE Chem. 466)

Experimental investigations have been made on various chemical solids as diffusible coating films for visual indication of boundary-layer transition in air and water. Originally, the method was applicable only at low speeds in wind tunnels and water tanks, and the indications were somewhat transient. More durable coating materials have now been made available, admitting of use at subsonic and supersonic wind-tunnel speeds from 30 to 1350 mph, and at ship-hull speeds from 2-1/2 to 20 kt. The method has also proved capable of extension to aircraft in flight at speeds from 100 to 445 mph at temperatures down to -22° C and at altitudes up to 20,000 ft. The diffusible-solid-coating method, with its advantages of autographic indication and simplicity and rapidity of operation, has thus become a versatile technique in investigations on fluid flow in aerodynamics and hydrodynamics.

RESONANT VIBRATION OF HELICOPTER ROTOR BLADES. J. Morris. 1954. 4p. diagr. (ARC R & M 2801; ARC 13,485. Formerly RAE SME 4042)

The blades of the operative rotors of helicopters are usually hinged both in the lift and rotational planes and it is because of this articulation that the blades in the course of rotation are akin dynamically to "pendulum vibration dampers." If the fundamental frequency of this species of pendulum vibration is numerically equal to nN where n is the number of blades and N is the frequency of rotation of the rotor then serious resonant forced vibration may ensue and it would appear that this is quite likely to occur in practical cases with the blades in vibration in the plane of rotation of the rotor.

Aeronautical Research Council (Gt. Brit.)
A NEW RELAXATIONAL TREATMENT OF THE COMPRESSIBLE TWO-DIMENSIONAL FLOW ABOUT AN AEROFOIL WITH CIRCULATION. L. C. Woods and A. Thom. 1954. 17p. diagrs., 2 tabs. (ARC R & M 2727. Formerly ARC 13,034; FM 1429; Oxford Univ., Engineering Lab. No. 35)

The method appears to be satisfactory treatment of the compressible flow of an inviscid fluid about an airfoil. Discrepancies with experiment appear at high Mach numbers due to the movement of the velocity peak towards the trailing edge where the boundary layer cannot be ignored. The airfoil used presented a difficult case for calculation as the nose was very sharp.

Department of Supply (Australia)
SOME CONTRIBUTIONS TO THE STUDY OF THE TURBULENT BOUNDARY-LAYER NEAR SEPARATION. B. G. Newman. March 1951. 40p. diagrs., photos. (Department of Supply. ACA-53)

An experimental and theoretical study is made of the turbulent boundary layer near separation in subsonic incompressible flow. A hot wire anemometer was developed and tested by measuring the shearing stress in turbulent flow down a circular pipe. The instrument was used in two series of measurements of turbulent boundary-layer flow near separation and some qualitative conclusions on turbulent separation are drawn. The use of the von Karman momentum equation as a means of determining the skin friction near separation is examined. Simple analysis of the flow in the laminar sublayer leads to estimation of skin friction in a turbulent boundary layer.

THE UNSTEADY BURNING OF CORDITE. J. D. Huffington. February 1954. 23p. diagrs., photos. (RAE Tech. Note RPD 95)

By burning cordite charges in small vented vessels an investigation has been made of chuffing (sporadic burning with the pressure falling to atmospheric between peaks) and of the continuous but oscillatory burning into which chuffing is transformed when the nozzle size is reduced. The observations lead to the postulate that burning during chuffing is thermal-explosive in nature. During a chuff, the surface layer of the propellant is first liquified and then immediately burns explosively down to a certain critical depth, the process being repeated during subsequent chuffs. Some information is given on steady oscillatory burning.

CALIBRATION OF THE R.A.E. NO.18 (9 IN. x 9 IN.) SUPERSONIC WIND TUNNEL. PART II - TESTS AT ATMOSPHERIC STAGNATION PRESSURE. W. T. Lord, G. K. Hunt, R. J. Pallant and J. Turner. September 1953. 25p. diagrs., 3 tabs. (RAE Tech. Note Aero 2236)

This report presents distribution of Mach number in the empty working section of the R.A.E. No. 18 (9- by 9-inch) supersonic wind tunnel at nominal Mach numbers of 1.4, 1.5, 1.6, 1.8, and 1.9, for condensation-free flow at atmospheric stagnation pressure and at a stagnation temperature of 35° C. The mean measured Mach numbers are 1.41, 1.61, 1.81, and 1.91 when calculated from values of pitot and stagnation pressures. The major contributions to the nonuniformity of the flow are from the disturbances which arise from the junctions of the windows with the side walls of the tunnels.

NOTE ON SAMPLING AND PHOTOGRAPHING CLOUD DROPLETS IN FLIGHT. F. J. Bigg and G. C. Abel. September 1953. 27p. diagrs., photos., tab. (RAE Tech. Note Mech. Eng. 156)

This note describes the progress made at R.A.E. and A. & A.E.E. in the development of a satisfactory means for determining the size and distribution of supercooled water droplets in icing clouds. The system is at present adequate for measuring in flight the median droplet diameter of liquid cloud droplets up to a speed of 220 knots. The system should be capable of development to a stage where with a possible flight speed limitation the liquid water content, total water content, and liquid median droplet diameter can be obtained under any type of icing condition.

INTERIM NOTE ON THE DEVELOPMENT OF A MAGNETIC POWDER CLUTCH. F. L. West. January 1954. 18p. diagrs. (RAE Tech. Note IAP 1028)

The most important test results obtained during the course of work on experimental magnetic powder clutches and iron powder materials in IAP Dept., RAE have been collected to illustrate difficulties being encountered with magnetic media for the guidance of future workers. The note covers an investigation of shear forces transmitted to a flat steel plate by magnetized iron powder media, and outlines phenomena observed during tests on experimental clutches of disk and cylinder rotor construction. The development and performance of a small cylinder clutch designed for use with an aircraft autopilot servoactuator is dealt with in some detail up to the stage of small quantity reproduction.

UNPUBLISHED PAPERS

N-15881*

ON A FEW METHODS OF RELAXATION CALCULATION. (Über einige Methoden der Relaxationsrechnung). Eduard Stiefel. April 1954. 50p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 3, no. 1, 1952, p. 1-33)

The general outlines of the so-called relaxation technique are developed. After a short discussion of the trial methods developed by Southwell and his school, allowing full leeway to the intuition of the computing person, the general mathematical background is treated. After a study of the gradient method, it is shown that relaxation methods are not necessarily successive approximations taking an infinite number of steps but that it is possible to speed up convergence such that the desired result is reached in a finite number of steps. These methods may be suitable for use on a sequence-controlled computing machine.

Iowa State College, Iowa Engineering Experiment Station. HEAT CAPACITY LAG OF GAS MIXTURES. Thomas D. Rossing and Sam Legvold. August 31, 1953. (i), 49p. diagrs., 4 tabs. (Iowa State College, Iowa Engineering Experiment Station)

The vibrational relaxation time has been measured in monochlorodifluoromethane (Freon 22) and its mixtures with argon and helium. The addition of argon or helium is found to reduce slightly the time necessary to excite molecular vibrations. Freon 22 is found to have a single relaxation time, and binary collisions are responsible for its vibrational excitation. The interferometer has been calibrated for absorption measurements. Absorption measurements are reported for Freon 22, argon, and a 9:1 mixture of the latter two.

Calif. Institute of Technology, Pasadena. Guggenheim Aeronautical Lab. THE LIFT OF THIN AIRFOILS AT HIGH-SUBSONIC SPEEDS. William W. Willmarth. September 1953. v, 87p. diagrs., photos. (Calif. Institute of Technology, Pasadena. Guggenheim Aeronautical Lab.)

Experimental results are presented for the lift characteristics of thin, two-dimensional airfoils at high-subsonic speeds and small angles of attack. Symmetrical airfoils with different locations of maximum thickness were investigated. Flow fields over each airfoil are discussed and the quantitative results for the lift and location of the center of lift are compared with theory. The effects of flow separation caused by boundary-layer shock-wave interaction are noted and discussed. The possibility of the forced oscillation of control surfaces due to boundary-layer separation is mentioned.

Univ. of Fla., Engineering and Industrial Experiment Station. HEAT TRANSFER TO CLOUDS OF PARTICLES AT ELEVATED TEMPERATURES. Robert B. Bennett, C. M. Oktay and B. G. Kyle. February 10, 1954. (iii), 81p. diagrs., photos., 34 tabs. (Univ. of Fla., Engineering and Industrial Experiment Station)

Sand and glass beads were dropped at various rates through still air at various temperatures. Overall heat-transfer coefficients and the radiation component of heat transfer were calculated. Experimental results show that heat transmission takes place principally by convection at low temperatures, and by radiation to an increasing extent at high temperatures. Of all the variables tried, the feed rate had the greatest effect on the overall coefficient of heat transfer. Presumably this was due to the shielding effect of the increase in cloud concentration.

STATIC MEASUREMENT OF AERODYNAMIC ROLLING DERIVATIVES. (Mesure statique des dérivées aérodynamiques de roulis). M. Bismut. April 1954. 17p. diagrs., photo. (Trans. from Recherche Aeronautique, no. 30, 1952, p. 9-13)

Conventional wind-tunnel balances permit measurement of the forces as a function of the components of the velocity of the center of gravity. Complementary methods must be employed for the measurement of forces as a function of the rotation of the axes fixed in the airplane. The procedure described has permitted measurement of the forces due to the rolling component (the reduced rolling velocity) in subsonic and supersonic wind tunnels.

NACA Rept. 1126

THE EFFECT OF BLADE-SECTION THICKNESS RATIOS ON THE AERODYNAMIC CHARACTERISTICS OF RELATED FULL-SCALE PROPELLERS AT MACH NUMBERS UP TO 0.65. Julian D. Maynard and Seymour Steinberg. 1953. ii, 55p. diagrs., photos., tab. (NACA Rept. 1126. Formerly RM L9D29)

Results of an investigation of two full-scale NACA propellers are presented for a range of blade angles from 20° to 55° at airspeeds up to 500 miles per hour. These results are compared with the results from previous tests of five related NACA propellers to evaluate the effects of blade-section thickness ratios on propeller aerodynamic characteristics.

NACA Rept. 1136

ESTIMATION OF THE MAXIMUM ANGLE OF SIDESLIP FOR DETERMINATION OF VERTICAL-TAIL LOADS IN ROLLING MANEUVERS. Ralph W. Stone, Jr. 1953. ii, 12p. diagrs., 5 tabs. (NACA Rept. 1136. Formerly TN 2633)

This paper presents the results of a study, by a step-by-step integration of the equations of motion, of the variations of angle of sideslip and angle of attack in rolling maneuvers, particularly for airplanes with mass distributed mainly along the fuselage. The results are compared with those of existing methods for estimating angles of sideslip for determining vertical-tail loads in rolling maneuvers.

NACA RM 54D01

DEVELOPMENT OF METAL-BONDING ADHESIVES WITH IMPROVED HEAT-RESISTANT PROPERTIES. John M. Black and R. F. Blomquist, Forest Products Laboratory. May 1954. 12p., 3 tabs. (NACA RM 54D01)

Results are reported of current studies at the Forest Products Laboratory to develop a metal-bonding adhesive with greater resistance to temperatures up to 600° F that is easier to use than present ones.

NACA TN 3080

MEASUREMENT AND ANALYSIS OF WING AND TAIL BUFFETING LOADS ON A FIGHTER-TYPE AIRPLANE. Wilber B. Huston and T. H. Skopinski. May 1954. i, 86p. diagrs., photo., 8 tabs. (NACA TN 3080)

Wing and tail buffeting loads measured in 194 runs with a fighter-type airplane are tabulated with the associated flight conditions. Measurements were made at altitudes of 30,000 to 10,000 feet and at Mach numbers up to 0.8. Preliminary analysis indicates that the loads vary with the square root of the dynamic pressure and shows the effects of aerodynamic damping, duration of buffeting, maneuver abruptness, penetration beyond the buffet boundary, and reduction of the wing natural frequency in bending through addition of wing-tip weights.

NACA TN 3083

DETERMINATION OF LATERAL-STABILITY DERIVATIVES AND TRANSFER-FUNCTION COEFFICIENTS FROM FREQUENCY-RESPONSE DATA FOR LATERAL MOTIONS. James J. Donegan, Samuel W. Robinson, Jr. and Ordway B. Gates, Jr. May 1954. 61p. diagrs., 12 tabs. (NACA TN 3083)

A method is presented for calculating the lateral-stability derivatives and lateral transfer-function coefficients from frequency-response data for a rigid airplane. Two examples are used to illustrate the method. Accurate lateral-stability derivatives can be obtained only when accurate frequency-response data are available.

NACA TN 3148

EVALUATION OF ALLOYS FOR VACUUM BRAZING OF SINTERED WROUGHT MOLYBDENUM FOR ELEVATED-TEMPERATURE APPLICATIONS. Kenneth C. Dike. May 1954. 13p. diagrs., photos., 2 tabs. (NACA TN 3148)

The brazing characteristics of 28 alloys, with liquidus temperatures in the range 2000° to 2500° F, were established in vacuum. The tensile strength of butt-brazed molybdenum joints of 10 of the alloys ranged from 21,000 to 49,000 pounds per square inch at room temperature and 0 to 18,900 pounds per square inch at 1800° F. The three alloys having 1800° F bonding strengths greater than 17,000 pounds per square inch were heated in vacuum for 24 hours at 1800° F to determine the effect on tensile strength.

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1724 F ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

This treatment lowered the strength of one considerably but did not seem to affect the 84 percent nickel - 16 percent titanium and 52 percent niobium - 48 percent nickel alloy bonds. Therefore, these two alloys may be potentially useful for brazing molybdenum.

NACA TN 3156

CHARTS FOR ESTIMATING TAIL-ROTOR CONTRIBUTION TO HELICOPTER DIRECTIONAL STABILITY AND CONTROL IN LOW-SPEED FLIGHT. Kenneth B. Amer and Alfred Gessow. May 1954. 54p. diagrs., photo., 2 tabs. (NACA TN 3156)

Theoretically derived charts and equations are presented by which tail-rotor design studies of directional trim and control response at low forward speed can be conveniently made. Comparisons between theoretical and experimental results are presented. The charts indicate and flight tests confirm that, under certain flight conditions, a region of vortex roughness is encountered by the tail rotor, making prolonged operation difficult in this region.

NACA TN 3173

A STUDY OF HYPERSONIC SMALL-DISTURBANCE THEORY. Milton D. Van Dyke. May 1954. 51p. diagrs. (NACA TN 3173)

The small-disturbance equations are derived for inviscid flow past thin bodies at high supersonic speeds. Reinterpreted, they apply throughout the supersonic range. The theory is used to find pressures on cones and wedges, initial gradients on ogives, and initial pressure curvatures on ogives of revolution. Additional approximations from existing theories are discussed.

NACA TN 3175

DOWNWASH CHARACTERISTICS AND VORTEX-SHEET SHAPE BEHIND A 63° SWEPT-BACK WING-FUSELAGE COMBINATION AT A REYNOLDS NUMBER OF 6.1×10^{6}. William H. Tolhurst, Jr. May 1954. 45p. diagrs., photo. (NACA TN 3175. Formerly RM A52J08)

Downwash-angle contour maps are presented for nine vertical transverse planes located between 0.57 and 2.71 semispans aft of the 0.25 mean aerodynamic chord point for three angles of attack. The shape of the vortex sheet is presented for the various survey planes and angles of attack. Theoretical and experimental downwash angles are compared.

NACA TN 3176

WALL INTERFERENCE IN WIND TUNNELS WITH SLOTTED AND POROUS BOUNDARIES AT SUBSONIC SPEEDS. Barrett S. Baldwin, Jr., John B. Turner and Earl D. Knechtel. May 1954. 42p. diagrs. (NACA TN 3176. Formerly RM A53E29)

Linearized compressible-flow analysis is applied to the study of wind-tunnel-wall interference for subsonic flow in either two-dimensional or circular test sections having slotted or porous walls. Expressions are developed for evaluating blockage and lift interference.

NACA TN 3181

EXPERIMENTAL INVESTIGATION OF HEAT-TRANSFER AND FLUID-FRICTION CHARACTERISTICS OF WHITE FUMING NITRIC ACID. Bruce A. Reese and Robert W. Graham, Purdue University. May 1954. 46p. diagrs., tab. (NACA TN 3181)

Experiments have been conducted to determine the heat-transfer and fluid-friction characteristics of white fuming nitric acid over a wide range of conditions. A satisfactory equation for relating the Fanning friction coefficient with heat transfer and the isothermal friction coefficient measured at the same Reynolds number is presented. An equation is also presented for correlating the heat-transfer results. Some preliminary results are presented for the regime of forced convection with nucleate boiling.

NACA TN 3182

MANUAL OF THE ICAO STANDARD ATMOSPHERE. CALCULATIONS BY THE NACA. International Civil Aviation Organization, Montreal, Canada and Langley Aeronautical Laboratory, Langley Field, Va., U.S.A. May 1954. iii, 132p. incl. 102p. tabs., diagrs. (NACA TN 3182. Supersedes and extends NACA Rept. 218)

The physical constants and basic equations defining the International Civil Aviation Organization (ICAO) Standard Atmosphere are presented together with tables and diagrams of the properties of the ICAO Standard Atmosphere computed by the National Advisory Committee for Aeronautics in both metric and English units for altitudes from -5,000 meters to 20,000 meters and from -16,500 feet to 65,800 feet.

NACA TN 3186

EVALUATION OF THE ACCURACY OF AN AIRCRAFT RADIO ALTIMETER FOR USE IN A METHOD OF AIRSPEED CALIBRATION. Jim Rogers Thompson and Max C. Kurbjun. May 1954. 15p. diagrs., photos., tab. (NACA TN 3186)

A method which may provide a rapid and convenient means for calibrating the airspeed systems of high-performance aircraft is proposed and discussed. The accuracy of the method is comparable with that of the NACA radar phototheodolite method (NACA Rep. 985), but the tests must be performed over a large body of water.

NACA TN 3201

DIRECTIONAL STABILITY CHARACTERISTICS OF TWO TYPES OF TANDEM HELICOPTER FUSELAGE MODELS. James L. Williams. May 1954. 44p. diagrs., photos. (NACA TN 3201)

The results of a low-speed wind-tunnel investigation of the directional stability characteristics of an overlap-type fuselage as affected by fuselage and pylon (vertical tail) modifications and of a nonoverlap type fuselage as influenced by spoilers and vertical-tail changes are presented in this report. Tuft-grid pictures of the air flow behind the nonoverlap type fuselage are also presented.

NACA TN 3210

THE ROLE OF TRIPLE COLLISIONS IN EXCITATION OF MOLECULAR VIBRATIONS IN NITROUS OXIDE. Richard A. Walker, Thomas D. Rossing and Sam Legvold, Iowa State College. May 1954. 24p. diagrs., photo., 3 tabs. (NACA TN 3210)

Results are presented of an investigation to determine the importance of triple collisions in the thermal relaxation process (heat capacity lag) of gaseous mixtures. The experimental work involved the measurement at ultrasonic frequencies of the velocity of sound in mixtures of the basic dispersive gas nitrous oxide and impurity gases nitrogen, helium, and argon. Wide ranges of pressures and concentrations for the gas mixtures were required in the experiments to ascertain the possible effects of triple collisions. The rudiments of the theory of sound dispersion and relaxation phenomena are presented along with an analysis of the manner in which the effects of triple collisions might be determined.

EXPERIMENTS ON THE FLOW PAST A POROUS CIRCULAR CYLINDER FITTED WITH A THWAITES FLAP. R. C. Pankhurst and B. Thwaites. APPENDIX II - SMOKE VISUALIZATION OF FLOW PAST CIRCULAR CYLINDER WITH THWAITES FLAP. W. S. Walker. 1953. 28p. diagrs., photos. (ARC R & M 2787. Formerly ARC 13,447; FM 1486; 13,507; FM 1496)

This paper describes wind-tunnel experiments on a porous circular cylinder of 3-inch diameter fitted with a Thwaites flap. Measurements were made of the pressure distribution at midspan, together with a number of wake traverses, over a range of suction quantity, flap size, wind speed, and flap setting. The distributed suction effectively prevented boundary layer separation and enabled a close approximation to potential flow to be achieved. The flap was essential to the attainment of steady flow conditions with suction.

RECORDS OF MAJOR STRENGTH TESTS. P. B. Walker. 1954. 5p. diagrs., tab. (ARC R & M 2790; ARC 12,601. Formerly RAE Structures 44)

The strength attained in major strength tests, made over a period of 10 years, is given for 24 wing systems and 10 fuselages. A preliminary analysis is also presented from the standpoints of safety and design efficiency. One third of all the wing systems tested are found to be seriously understrength as originally designed, and it is concluded that wing and fuselage testing for all new types is essential for safety. The majority of understrength aircraft, however, were brought up to the required standard by local strengthening, and it is concluded that this has an important bearing on design efficiency.

THE EFFECT OF SWEEPBACK ON THE FUNDAMENTAL DERIVATIVE COEFFICIENT FOR FLEXURAL MOTION. J. B. Bratt and K. C. Wight. 1953. 22p. diagrs., photos., 5 tabs. (ARC R & M 2774. Formerly ARC 13,452; 0.898; S & C 2438)

Measurements have been made with new equipment for derivative tests in a 9- by 7-foot tunnel, to determine the effect of sweepback on the derivatives $\lambda_{\dot{\phi}}$ and λ_{ϕ} for a rectangular airfoil of aspect ratio 6. A numerical reduction was observed in each case. Values of $\lambda_{\dot{\theta}}$ and λ_{θ} for the swept model were obtained from measurements relating to oscillation about an axis perpendicular to the leading edge. A comparison of $\lambda_{\dot{\phi}}$ and λ_{ϕ} with available theoretical results for finite aspect ratio is made and good agreement observed in the case of the former. The less satisfactory agreement with λ_{ϕ} is thought to be due to lower accuracy of the theoretical values.

AN INVESTIGATION OF HIGH-ALTITUDE CLEAR-AIR TURBULENCE OVER EUROPE USING MOSQUITO AIRCRAFT. G. S. Hislop and D. M. Davies. 1953. 39p. diagrs., 3 tabs. (ARC R & M 2737; ARC 13,316. Formerly Brit. European Airways Corp. RSD Rept. 15)

Some 20 areas of turbulence were actually investigated, the greatest vertical gust velocity encountered was 26 ft/sec E.A.S. The results were examined

from the passenger comfort and structural aspect, and from the meteorological aspect. More data are needed before a forecasting technique can be established. It has been found that severe turbulence may be found in a jet stream and that turbulence is frequently found near the tropopause.

THE PERFORMANCE AFTER POWER FAILURE OF A HELICOPTER WITH BLADE PITCH CONTROL. PARTS I AND II. F. O'Hara and H. A. Mather. 1953. 16p. diagrs. (ARC R & M 2797; ARC 12,892; ARC 13,867. Formerly Airborne Forces Exp. Establishment AFEE Rept. Rota 1; AFEE Rept. Rota 6)

In part I, a review is made of helicopter performance after engine failure. Transition from powered operation to autorotation is discussed and a theoretical analysis of the motion is given for a single-rotor helicopter with blade-pitch control. In part II, tests are made to investigate the performance of a Hoverfly I in the transition to autorotation following power cut in level flight.

A SURVEY OF PERFORMANCE REDUCTION, WITH PARTICULAR REFERENCE TO TURBO-PROPELLER AIRCRAFT. K. J. Lush. 1954. 7p. (ARC R & M 2757; ARC 12,951. Formerly AAEE/Res/247)

A survey of the methods available for performance reduction, with particular reference to turbo-propelled aircraft, has been made. The purpose of performance reduction is briefly examined. Methods in use are classified into experimental methods, which require no advance numerical data, and analytical methods, which require such data. The latter class if subdivided into methods based on small corrections and methods based on performance analyses. The suitability of each class of method is discussed.

SOME ADDITIONAL NOTES ON THE DERIVATION OF AIRWORTHINESS PERFORMANCE CLIMB STANDARDS. A. K. Weaver. 1953. 12p. diagr. (ARC R & M 2769; ARC 13,500. Formerly AAEE/Tech/61)

After the publication of a report (R & M 2631) on the derivation of airworthiness performance climb standards, various subsidiary points raised in the course of discussions were examined. Some of these have been collected together in the present note. They are in the nature of elaborations of the original method and include a refined method of deriving the take-off climb standard, a method of treating interdependence of engine failure and a method for including the effect of sideslip in the margin allowed for pilotage errors. The main principles set forth in the earlier report remain unaffected.

PRESSURE DISTRIBUTION AND BOUNDARY LAYER INVESTIGATIONS ON 44 DEGREE SWEPT-BACK TAPERED WING. PART I - THREE-DIMENSIONAL TESTS ON THE WING. PART II - TWO-DIMENSIONAL PRESSURE DISTRIBUTION TESTS ON 10 PER CENT THICK SYMMETRICAL AEROFOIL SECTION. Joseph Black. 1953. 52p. diagrs., photos., 2 tabs. (ARC CP 137)

Chordwise pressure distributions at a number of spanwise locations were measured over a range of incidence. Attention was given to investigating the boundary layer, quantitative measurements being made with a novel form of yawmeter head. A technique for revealing the direction of flow and formation of vortices in the layer was developed. One of the most important results established was the relation of the unstable break in the pitching-moment curve to the initiation of stalling at the tip.

A REVIEW AND ASSESSMENT OF VARIOUS FORMULAE FOR TURBULENT SKIN FRICTION IN COMPRESSIBLE FLOW. R. J. Monaghan. 1953. 52p. diagrs. (ARC CP 142)

An extended comparison is made of available formulas which have been developed for the variation of turbulent skin friction on a flat plate in compressible flow, with and without heat transfer. Assumptions made in their development are examined and are checked against experimental evidence where possible. A formula is given which should be sufficiently accurate in application probably up to M = 4 until further experimental evidence may make refinement possible.

AN INVESTIGATION INTO THE PITOT RAKE METHOD OF MEASURING TURBO JET ENGINE THRUST IN FLIGHT. J. Stephenson, R. T. Shields and D. W. Bottle. 1954. 60p. diagrs., 9 tabs. (ARC CP 143)

Tests were made to find whether a pitot rake could be used as an absolute measure of the thrust of a jet engine on the ground and in flight. The tests were made on Derwent 5 engines installed in Meteor 4 aircraft. The test covered a wide range of flight conditions and included test bed measurements on bare engines and later, measurements of exit static pressure. The same final nozzle was used in all the main tests. The tests were also planned to check the generally nondimensional thrust relationship for jet engines.

EXPERIMENTAL WORK ON THE ELECTROSTATIC CHARGES FORMED ON AIRCRAFT CAMERA FILM. J. A. Wells. October 1953. 50p. diagrs., photos., 4 tabs. (RAE Tech. Note Ph. 479)

The note gives a survey of the existing information on frictional electricity with particular reference to its application to "static" on aircraft camera film. Suitable equipment for the measurement of frictional charges is described. Some limited experimental work on the distribution of charge which occurs when a dielectric rubs continuously over a fixed surface and a method of assessing films for liability to static discharge are described. Recommendations are made for methods of reducing the occurrence of discharges.

National Gas Turbine Establishment (Gt. Brit.)
SOME EXPERIMENTS ON THE MEASUREMENT OF AIR FLOW BY TRAVERSING A DUCT. H. A. Knight. November 1953. 51p. diagrs. (NGTE Memo. M. 178)

Experiments to obtain a reliable aerodynamic calibrating technique in a measuring duct are summarized. The final result was only partly successful and the method has been postponed while an alternative is tried. The tests resulted from attempts to reduce errors as they were discovered. The principle source of inaccuracy with the original method was the static pressure variation across the measuring plane. Features of the experiments which are applicable to general flow measurements are listed. Three untried improvements are listed.

THE INFLUENCE OF THE EXIT VELOCITY PROFILE ON THE NOISE OF A JET. Alan Powell. September 22, 1953. 20p. diagrs., 4 tabs. (ARC 16,156; FM 1952. Formerly ARC 15,473; FM 1837)

The noise levels of a jet issuing from a long pipe are compared with those of a jet having a square velocity profile at the exit. On comparison with a jet of smaller diameter which has an equal thrust for the same maximum jet velocity, it is found that the changes in noise level are smaller. For jets of equal diameters the effects on the subsonic aerodynamic noise generated by a reduction of velocity gradient near the boundary are more than offset by the increased velocities necessary near the center of the jet to obtain equal thrust.

THE SLIP BAND EXTRUSION EFFECT OBSERVED IN SOME ALUMINIUM ALLOYS SUBJECTED TO CYCLIC STRESSES. P. J. E. Forsyth and C. A. Stubbington. January 1954. 19p. diagrs., photos. (RAE Met. 78)

Extrusion of crystal material from slip bands has been observed during the final stages of fatiguing of a number of solution heat treated materials. The extruded material is in the form of ribbon, the thickness of which is estimated as less than 0.1 μ. It appears suddenly after a period of cyclic stressing, and leaves behind a crevasse which represents the initial crack. The effect may be associated with a segregation or ordering of the solute atoms in the lattice. This ordering may to a certain extent already exist in the solution heat treated material, but is mainly caused by the action of the cyclic stresses on the metastable matrix.

THE DIVIDED-FLOW "ASPIN I" TURBOJET. (Le réacteur a double flux). M. Faury. May 1954. 25p. diagrs., photo., 3 tabs. (See also Docaero, no. 6, Nov., 1950, p. 19-38)

The propulsive efficiency of propellers, even of the most modern type, drops rapidly at speeds above 700/km/h, while that of jet engines is not important at speeds below 900 km/h. The range between these two limits, that of the heavy airplanes of tomorrow, demands a new propeller. The divided-flow turbojet, midway between turbojet and simple jet, seems best suited for this purpose.

CURRENT NACA REPORTS

NACA Rept. 1132

LAMINAR BOUNDARY LAYER ON CONE IN SUPERSONIC FLOW AT LARGE ANGLE OF ATTACK. Franklin K. Moore. Appendix B: NUMERICAL SOLUTION OF DIFFERENTIAL EQUATIONS. Lynn Albers. 1953. ii, 13p. diagrs. (NACA Rept. 1132. Formerly TN 2844)

The laminar boundary-layer flow about a cone at large angles of attack to a supersonic stream has been analyzed in the plane of symmetry. At the bottom of the cone, velocity profiles were obtained showing the expected tendency of the boundary layer to become thinner on the under side of the cone as the angle of attack is increased. At the top of the cone, the analysis failed to yield unique solutions, except for small angle of attack. Beyond a certain critical angle of attack, boundary-layer flow does not exist in the plane of symmetry, thus indicating separation.

NACA Rept. 1139

CHARTS AND APPROXIMATE FORMULAS FOR THE ESTIMATION OF AEROELASTIC EFFECTS ON THE LATERAL CONTROL OF SWEPT AND UNSWEPT WINGS. Kenneth A. Foss and Franklin W. Diederich. 1953. iii, 25p. diagrs., 2 tabs. (NACA Rept. 1139. Formerly TN 2747)

Charts and approximate formulas are presented for the estimation of static aeroelastic effects on the spanwise lift distribution, rolling-moment coefficient, and rate of roll due to aileron deflections on swept and unswept wings at subsonic and supersonic speeds. Some design considerations brought out by the results of this paper are discussed.

NACA Rept. 1148

A SPECIAL INVESTIGATION TO DEVELOP A GENERAL METHOD FOR THREE-DIMENSIONAL PHOTOELASTIC STRESS ANALYSIS. M. M. Frocht and R. Guernsey, Jr., Illinois Institute of Technology. 1953. ii, 17p. diagrs., photos., 3 tabs. (NACA Rept. 1148. Formerly TN 2822)

The method of strain measurement after annealing is reviewed and found to be unsatisfactory for the materials available in this country. A new, general method is described for the photoelastic determination of the principal stresses at any point of a general body subjected to arbitrary loads. The method has been applied to a sphere subjected to diametral compressive loads. The results show possibilities of high accuracy.

NACA RM 54D19

PRELIMINARY MEASUREMENTS OF TURBULENCE AND TEMPERATURE FLUCTUATIONS BEHIND A HEATED GRID. A. L. Kistler, V. O'Brien and S. Corrsin, Johns Hopkins University. June 1954. 24p. diagrs., photo. (NACA RM 54D19)

Preliminary measurements have been made of velocity and temperature fluctuations in the flow behind a heated grid in a uniform air stream. Temperature correlation shows a reasonable degree of isotropy, and the temperature fluctuations die out at large distances more slowly than the turbulence, as has been predicted theoretically under some strongly simplifying postulates.

NACA TN 3072

A THEORETICAL INVESTIGATION OF THE AERODYNAMICS OF WING-TAIL COMBINATIONS PERFORMING TIME-DEPENDENT MOTIONS AT SUPERSONIC SPEEDS. John C. Martin, Margaret S. Diederich and Percy J. Bobbitt. May 1954. 226p. diagrs., tab. (NACA TN 3072)

A theoretical investigation is presented on the contribution of the horizontal tail to the lift and pitching moment due to angle of attack, a constant rate of pitch, and a constant vertical acceleration. Numerical values of the aerodynamic coefficients associated with these motions are presented for a number of two-dimensional wing-tail combinations, a triangular-wing—triangular-tail combination, and a number of rectangular-wing—triangular-tail combinations. A method of treating unsteady aerodynamics based on an infinite series of stability derivatives of successively higher order is presented. Methods for calculating the flow fields behind wings with a constant vertical acceleration are developed. Calculated results are presented for the upwash behind two-dimensional wings and for certain regions behind triangular and rectangular wings for a constant rate of pitch and for a constant rate of vertical acceleration.

NACA TN 3150

METHOD FOR RAPID DETERMINATION OF PRESSURE CHANGE FOR ONE-DIMENSIONAL FLOW WITH HEAT TRANSFER, FRICTION, ROTATION, AND AREA CHANGE. James E. Hubbartt, Henry O. Slone and Vernon L. Arne. June 1954. 22p. diagrs., 2 tabs. (NACA TN 3150)

An approximate method for rapid determination of the pressure change for subsonic flow of a compressible fluid under the simultaneous action of heat transfer, friction, rotation, and area change is developed. In the development of this method, the momentum equation was approximated and re-

arranged for a convenient solution employing charts. This report presents the analysis involved in simplifying the momentum equation, the charts necessary for obtaining particular solutions, and comparisons with more rigorous numerical solutions with conditions typical for air-cooled turbine blades.

NACA TN 3174

INFLUENCE OF AIRFOIL TRAILING-EDGE ANGLE AND TRAILING-EDGE-THICKNESS VARIATION ON THE EFFECTIVENESS OF A PLAIN FLAP AT HIGH SUBSONIC MACH NUMBERS. Albert D. Hemenover and Donald J. Graham. June 1954. 101p. diagrs., photos., 5 tabs. (NACA TN 3174. Formerly RM A51C12a)

The effects of variation of trailing-edge angle and trailing-edge thickness on the characteristics of a 10-percent-chord thick NACA airfoil section with a 25-percent-chord plain flap are appraised from wind-tunnel tests at Mach numbers from 0.3 to 0.9 and Reynolds numbers varying correspondingly from 1 to 2 million. The airfoil trailing-edge angle was varied from 18° to 6°, and the trailing-edge thickness from zero to the thickness at the flap hinge line.

NACA TN 3207

ROLE OF NICKEL DIP IN ENAMELING OF SHEET STEEL. D. G. Moore, J. W. Pitts and W. N. Harrison, National Bureau of Standards. June 1954. 27p. diagrs., photos., 8 tabs. (NACA TN 3207)

An investigation was made of the effects of the firing time and the weight of the nickel deposited from the nickel-dip solution on the adherence developed by a cobalt-free and a cobalt-bearing ground-coat enamel on both enameling iron and a titanium-bearing low-carbon steel.

NACA TN 3215

TESTS OF BONDED AND RIVETED SHEET-STRINGER PANELS. Leonard Mordfin and I. E. Wilks, National Bureau of Standards. June 1954. 45p. diagrs., photos., 5 tabs. (NACA TN 3215)

Bending and compression tests were performed on 21 sheet-stringer panels of 75S-T6 aluminum alloy having alclad sheets nominally 0.051 inch thick and stringers nominally 3-1/2 inches apart. Nine panels had I-stringers bonded to the sheets with Araldite Type I adhesive, three panels had I-stringers bonded to the sheets with Metlbond adhesive, and nine panels had Z-stringers riveted to the sheets. All tests were carried to failure and strain and deformation measurements were made. The test results did not indicate any great superiority of one type of construction over the other but rather that the choice in any given case would depend upon the particular designs being compared. They also showed that the scatter of results obtained with bonded construction was not significantly greater than that obtained with riveted construction and that cleavage was not always the governing factor in the strength of bonded panels.

Royal Aircraft Establishment (Gt. Brit.)
A HIGH SPEED ELECTRO-MECHANICAL MULTIPLIER. C. A. A. Wass and D. W. Allen. February 1954. 13p. diagrs., photos. (RAE Tech.Note GW 300)

Requirements exist in simulator work for a simple high-speed squaring and multiplying unit of moderate accuracy. This note describes a simple electro-mechanical multiplier using a type E.4 relay as a position servo driving a potentiometer. The unit will operate on frequencies up to 15 cps without introducing any appreciable phase shift. Accuracy depends primarily on the quality of the potentiometers used but maximum errors of 1 percent of the maximum output appear possible.

Royal Aircraft Establishment (Gt. Brit.)
A NOTE ON THE USE OF STRAIN GAUGES IN WIND TUNNEL BALANCES. J. R. Anderson. January 1954. 28p. diagrs., photos. (RAE Tech. Note Aero 2290)

This note is substantially that presented at the NATO/AGARD wind tunnel and model testing panel on September 3, 1953. It reviews briefly some of the experience obtained in the employment of wind-tunnel balances using bonded, resistance type electrical strain gages, in the smaller high-speed wind tunnels of Aerodynamics Department. The effects of temperature on the strain gages are discussed and shown to be a major limitation in their use. A self-balancing potentiometer instrument, specially designed and developed for use with wind-tunnel strain-gage balances, is also described briefly.

N-30837*

Marine Aircraft Experimental Establishment (Gt. Brit.) THE DEVELOPMENT OF A MINIATURE PRESSURE PICK-UP. J. K. Friswell. March 1954. 10p. diagrs., photos. (MAEE F/TN/3)

Details are given of the construction of a miniature pressure pickup of the diaphragm and strain-gaged cantilever type. The unit is cylindrical, with overall diameter 1 inch and overall length 2 inches, its weight being 1.9 ounces. It is designed to operate in the range 0-20 psi and will record either positive or negative pressures. It can be readily adapted for use over a much greater pressure range. It is easy to service.

N-30839*

Marine Aircraft Experimental Establishment (Gt. Brit.) ASSESSMENT OF REVERSIBLE PITCH PROPELLER TRAIL INSTALLATION - SOLENT N. J. 201. J. Taylor. March 1954. 23p. diagrs., photos., 2 tabs. (MAEE F/TN/2)

An assessment was required on the operation of the reversible pitch propeller trial installation, on the Solent N. J. 201, as part of a general research program for seaplanes. Results are given with the reversing pitch propellers fitted to the inboard engines in tests on low speed maneuvering, particularly in buoy approaches, and when used as braking units during landing. Some brief turning circle measurements have also been done.

Aeronautical Research Council (Gt. Brit.) THE PERFORMANCE OF THE 108 COMPRESSOR FITTED WITH LOW STAGGER FREE VORTEX BLADING. D. V. Foster. 1954. 36p. diagrs., photos. (ARC CP 144)

A large three-stage compressor is described which is designed for detail three-dimensional flow investigations. Particular attention has been paid to the accuracy of measurement on the rig and it is shown that the main errors are due to the unsteady nature of the flow and to speed fluctuations. Test characteristics of the first set of low stagger free vortex blading are presented and compared with various theoretical performance calculations. A description of the surging behavior of the compressor and the effect of blade position upon the measured static pressure are given.

N-30844*

Aeronautical Research Council (Gt. Brit.) ZERO LIFT DRAG MEASUREMENTS ON SWEPT WINGS AT TRANSONIC AND SUPERSONIC SPEEDS USING THE GROUND-LAUNCHED ROCKET-BOOSTED MODEL TECHNIQUE. T. Lawrence and C. Kell. 1954. 35p. diagrs., photo., tab. (ARC CP 145)

This is mainly a documentary record of drag measurements on 14 swept wings varying in plan form from deltas to swept untapered wings from 4 percent to 10 percent thick. Results are compared with theory for wings of double-wedge section; an attempt is made to check the validity of supersonic similarity laws. Three primary conclusions are drawn; at supersonic speeds, wave drag of a given wing varies as the square of thickness ratio; supersonic similarity law allows drag of "similar" wings to be compared; drag of round-nose wings perhaps may be estimated from calculations of drag of double-wedge wings.

N-30845*

Aeronautical Research Council (Gt. Brit.) VIBRATION AND FLUTTER OF AIRCRAFT AERIALS. W. H. Johnson. 1954. 15p. diagrs., photos. (ARC CP 146)

Fatigue failures of blade and whip aircraft aerials have been investigated and it is shown that stalling flutter and mechanically excited vibration have both contributed in large measure to the failures. All the aerial types involved possess considerable flexibility and very low internal damping. It is shown that the introduction of damping into the mounting of the aerials has a very beneficial effect on their behavior as regards both flutter and mechanically excited vibration. Methods are described for preventing failure from either cause.

N-30846*

Aeronautical Research Council (Gt. Brit.) FACTORS INFLUENCING THE OPTIMUM AERODYNAMIC DESIGN OF COOLED TURBINES. G. F. C. Rogers. 1954. 27p. diagrs. (ARC CP 155)

Owing to the losses in performance which increase with the rate of heat extraction required for turbine cooling, it is desirable to know what range of aerodynamic designs is associated with low values of this quantity. Different aerodynamic designs of turbine, all passing the same mass flow and having approximately the same disc and blade stresses, have been compared on the basis of the ratio of heat extraction rate to work output. It is found that high values of flow coefficient are beneficial in this respect, and that impulse turbines have a slight advantage over reaction turbines.

N-30847*

Aeronautical Research Council (Gt. Brit.) THE EFFECT OF ROLLING ON FIN-AND-RUDDER LOADS IN YAWING MANOEUVRES. D. R. Puttock. 1954. 31p. diagrs., 3 tabs. (ARC CP 153)

Exact solutions are derived for angle of sideslip and fin-and-rudder loads for an aircraft performing two yawing maneuvers induced by the rudder. Angles of sideslip and fin-and-rudder loads are then calculated for three selected aircraft and compared with results obtained by a simplified method in which rolling motion is neglected. Further calculations are made using a modified method in which the coefficients of the response formulas of the simplified method have been adjusted to take some account of rolling. The analysis shows that errors of 20 percent may be incurred if rolling is neglected in the estimation of fin-and-rudder loads for aircraft with swept and delta wings.

N-30895*

Royal Aircraft Establishment (Gt. Brit.)
SECONDARY FLOW IN A BOUNDARY LAYER. L. Sowerby. March 1954. 21p. diagrs., tab. (RAE Aero 2512)

The laminar boundary layer on a flat plate is considered. It is shown that a secondary flow in the boundary layer is a consequence of curvature in the streamlines of the mainstream flow (in planes parallel to the plate). The special case in which the streamlines form a family of translates is discussed and the equations of possible families of streamlines are determined. The boundary-layer equations are solved in the case where the streamlines are a family of equal parabolas; this leads to an extension of Blasius' result for uniform flow over a flat plate. Finally, in the appendix, the skin friction coefficient is calculated, from which is obtained a quantity analogous to the profile-drag coefficient of a swept wing, for comparison with the results of Weber and Brebner for the latter case. The comparison confirms the assumptions made by them in the development of their theory.

Royal Aircraft Establishment (Gt. Brit.)
NOTES ON THE RESPONSE OF A LINEAR VIBRATION SYSTEM TO IMPACT LOADING. H. K. P. Neubert. March 1954. 21p. diagrs. (RAE Tech. Note Instn. 138)

In the course of investigations into the effect of impact loadings, the general equations for deflection, velocity, and acceleration of a linear system of one degree of freedom with velocity damping have been derived for a case of a mass being dropped onto a spring (with negligible mass). Response curves are plotted and discussed for two idealized cases of aircraft landing, and for a drop table test. The possible errors for a proposed integrating touch-down velocity meter are discussed. Frequency spectra for three typical impact curves have been computed and the error introduced when measuring the impact with an accelerometer of inadequate frequency response is discussed.

UNPUBLISHED PAPERS

N-1726*

ON SEVERAL MEASURES, TAKEN IN PRACTICE, FOR ELIMINATING OSCILLATORY YAW WITH FREE RUDDER. (Über einige praktisch durchgeführte Massnahmen zur Beseitigung von Gierschwingungen mit losem Ruder). R. Schmidt. April 1954. 10p. diagrs., photo. (Trans. from Lilienthal-Gesellschaft für Luftfahrtforschung, Berlin, Bericht 143, Nov. 6-7, 1941, p. 22-24)

Measures, tested and carried out on several airplanes at Dornier works when unsatisfactorily damped oscillatory yaw had occured, and its elimination by modifications of the tail had not been possible, are discussed. The two groups of measures discussed are measures which augment the increase of rudder moment in the region of zero position of the controls; and measures which impede the free motion relative to the air of the rudder.

N-31386*

MEASURES FOR ELIMINATION OF OSCILLATORY YAW WITH FREE RUDDER. (Massnahmen zur Beseitigung von Gierschwingungen mit losem Seitenruder). H. G. Schumann. April 1954. 6p. diagrs. (Trans. from Lilienthal-Gesellschaft für Luftfahrtforschung, Berlin, Bericht 143, Nov. 6-7, 1941, p. 27-29)

Experiences are given which were made with the Ju 88 in controlling oscillatory yaw with free rudder. This method of attaining the degree of rudder load reduction required in the individual case by the control force itself, involved the return to harmless variations of rudder-self-adjustment and eliminated thus for a long time the difficulties occurring now and again at other firms.

N-31449*

THEORETICAL AND EXPERIMENTAL STUDY OF THE MEANS OF PROTECTING AN AIRPLANE FROM GUST ACCELERATIONS. CHAPTER VIII - EXPERIMENTAL STUDY. (Recherches théoriques et expérimentales sur les moyens de soustraire un avion aux accélérations que peuvent engendrer les perturbations atmosphériques. Chapitre VIII - Étude expérimentale). René Hirsch. February 1954. 45p. diagrs., photos. (Trans. from Ministère de l'Air. Publications Scientifiques et Techniques, no. 138, 1938)

Changes in direction and intensity of the relative wind which strikes the airplane in flight induce changes in the total hinge moment of the controlled aileron so that the consecutive rotations of the latter produce exactly defined variations of the total lift coefficient. Two basic airfoils were studied, the Potez 403 and NACA 23012.

NACA Rept. 1140

CHARTS AND APPROXIMATE FORMULAS FOR THE ESTIMATION OF AEROELASTIC EFFECTS ON THE LOADING OF SWEPT AND UNSWEPT WINGS. Franklin W. Diederich and Kenneth A. Foss. 1953. iii, 48p. diagrs., 3 tabs. (NACA Rept. 1140. Formerly TN 2608)

Charts are presented for the estimation of aeroelastic effects on spanwise lift distribution, lift-curve slope, aerodynamic center, and damping in roll of swept and unswept wings at subsonic and supersonic speeds. Some design considerations brought out by the results of this paper are discussed.

NACA TM 1375

ON THE THREE-DIMENSIONAL INSTABILITY OF LAMINAR BOUNDARY LAYERS ON CONCAVE WALLS. (Über eine dreidimensionale Instabilität laminarer Grenzschichten an konkaven Wänden). H. Görtler. June 1954. 32p. diagrs. (NACA TM 1375. Trans. from Gesellschaft der Wissenschaften zu Göttingen, Nachrichten, Mathematik, v. 2, no. 1, 1940)

A study is made of the stability of laminar boundary-layer profiles on slightly curved walls relative to small disturbances that result from vortices whose axes are parallel to the principal direction of flow. The result is an eigenvalue problem by which, for a given undisturbed flow at a prescribed wall, the amplification or decay is computed for each Reynolds number and each vortex thickness. For neutral disturbances (zero amplification) a critical Reynolds number is determined for each vortex distribution. The numerical calculation produces amplified disturbances on concave walls only.

NACA RM E54E03

EFFECT OF HIGH PRESSURE ON SMOKING TENDENCY OF DIFFUSION FLAMES. Glen E. McDonald and Rose L. Schalla. June 1954. 7p. diagrs., tab. (NACA RM E54E03)

The variation in smoking tendency of a diffusion flame was measured over a pressure range of 4 to 20 atmospheres (abs) for the two fuel types ethane and ethylene. The fuels were burned as diffusion flames inside a pressure vessel equipped with windows for observation of the flame. It was found that the changes in flame height, which measures the relative amount of fuel that can be burned without producing smoke, vary inversely with the pressure.

NACA TN 3130

A PROCEDURE FOR THE DESIGN OF AIR-HEATED ICE-PREVENTION SYSTEMS. Carr B. Neel, Jr. June 1954. 63p. diagrs., photo. (NACA TN 3130)

The procedure to be followed in the design of aircraft ice-prevention equipment in which the components are protected by means of internally circulated heated air is outlined. In addition to presentation of the required heat-transfer and air-pressure-loss equations, a simple electrical analogue is described which was devised to facilitate the design of an air-heated system. An illustration is given of the application of the analogue to a design problem.

NACA TN 3153

VARIATION OF LOCAL LIQUID-WATER CONCENTRATION ABOUT AN ELLIPSOID OF FINENESS RATIO 5 MOVING IN A DROPLET FIELD. Robert G. Dorsch and Rinaldo J. Brun. July 1954. 68p. diagrs., photos., 2 tabs. (NACA TN 3153)

Analyses of calculated water-droplet trajectories show that the concentration of liquid water at various points about an ellipsoid of revolution moving through a droplet field varies considerably. Curves of local concentration factor as a function of spatial position are presented in terms of dimensionless parameters.

NACA TN 3154

INFRARED SPECTRA OF 47 DICYCLIC HYDROCARBONS. John H. Lamneck, Jr., Harold F. Hipsher and Virginia O. Fenn. June 1954. 34p. diagrs., 5 tabs. (NACA TN 3154)

The infrared spectra are presented for 47 dicyclic hydrocarbons consisting of some alkyldiphenylmethanes, alkyldicyclohexylmethanes, alkylnaphthalenes, alkyltetralins, 1,3-diphenyl-2-alkylpropanes and 1,3-dicyclohexyl-2-alkylpropanes. The physical properties of these highly purified compounds are included for reference purposes.

NACA TN 3161

AN INVESTIGATION OF THE USE OF ROCKET-POWERED MODELS FOR GUST-LOAD STUDIES WITH AN APPLICATION TO A TAILLESS SWEPT-WING MODEL AT TRANSONIC SPEEDS. A. James Vitale, H. Press and C. C. Shufflebarger. June 1954. 36p. diagrs., photos., tab. (NACA TN 3161)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

Flight tests in continuous rough air at transonic speeds have been made of a tailless 45° sweptback-wing rocket model as part of a program to investigate the feasibility of using existing rocket-model techniques for obtaining gust-loads information. The results of airplane flight surveys for determining a working basis for forecasting and selecting suitable test days are presented. Use is made of power-spectral methods of generalized harmonic analysis in presenting both the experimental and calculated characteristics of load response in rough air of a configuration having low damping in pitch.

NACA TN 3168

A NEW HODOGRAPH FOR FREE-STREAMLINE THEORY. Anatol Roshko, California Institute of Technology. July 1954. 39p. diagrs., 3 tabs. (NACA TN 3168)

The Helmholtz-Kirchhoff method for separated flow past a flat plate normal to the stream is modified to allow arbitrary separation velocity and base pressure so that values more in conformity with experiment may be chosen. The solution depends on a single base-pressure parameter k. The computations depend on a particular choice of free-streamline hodograph which gives a definite wake width for every value of k. In this way the wake width is correlated with the drag. Examples are worked out for a wedge and a circular cylinder.

NACA TN 3169

ON THE DRAG AND SHEDDING FREQUENCY OF TWO-DIMENSIONAL BLUFF BODIES. Anatol Roshko, California Institute of Technology. July 1954. 29p. diagrs., tab. (NACA TN 3169)

A semiempirical study was made of the bluff-body problem. The relation between the wake and the potential flow outside the wake and cylinder was studied and some experiments were made with interference elements in the wake close behind a cylinder. Free-streamline theory was combined with experimental results to obtain a correlation between bluff cylinders of different shapes.

NACA TN 3171

SOME NEW DRAG DATA ON THE NACA RM-10 MISSILE AND A CORRELATION OF THE EXISTING DRAG MEASUREMENTS AT M = 1.6 AND 3.0. Robert J. Carros and Carlton S. James. June 1954. 24p. diagrs., photos., tab. (NACA TN 3171)

Measurements of the zero-lift total drag of the NACA RM-10 missile were made on gun-launched, free-flight models at Mach numbers of 1.6 and 3.0 and corresponding Reynolds numbers of 3.0 million and 5.0 million. Results showed transition location to have an important effect on the drag. Results of this and several other investigations were correlated on the basis of considerations of Mach number, Reynolds number, transition location, and heat-transfer effects.

NACA TN 3180

DETERMINATION OF VISCOSITY OF EXHAUST-GAS MIXTURES AT ELEVATED TEMPERATURES. J. C. Westmoreland, National Bureau of Standards. June 1954. 41p. diagrs., photo., 10 tabs. (NACA TN 3180)

The viscosities of five samples of dry-exhaust-gas mixtures at approximately atmospheric pressure and at temperatures of from 0° to 1,100° C are presented. A method of analysis and correlation proposed by Sutherland has been applied to the data and equations were derived therefrom for representing the results. It is believed that these equations may be used for computing viscosities of all mixtures having compositions within the range of the five studied at any temperature up to about 1,300° C. The effect of moisture upon the viscosity of exhaust gas was computed by a relation developed from experimental values for moist air.

NACA TN 3185

TABLES FOR THE COMPUTATION OF WAVE DRAG OF ARROW WINGS OF ARBITRARY AIRFOIL SECTION. Frederick C. Grant and Morton Cooper. June 1954. 9p. diagr., 28p. tabs. (in pocket) (NACA TN 3185)

Tables and computing instructions are presented for the rapid evaluation of the wave drag of delta wings and of arrow wings having a ratio of the tangent of the trailing-edge sweep angle to the tangent of the leading-edge sweep angle from -1.0 to 0.8. The tables cover a range of both subsonic and supersonic leading edges.

NACA TN 3187

THE NEAR NOISE FIELD OF STATIC JETS AND SOME MODEL STUDIES OF DEVICES FOR NOISE REDUCTION. Leslie W. Lassiter and Harvey H. Hubbard. July 1954. 38p. diagrs., photos. (NACA TN 3187)

Experimental studies of the pressure fluctuations near jets were made during unchoked operation of both a full-scale turbojet engine and a 1-inch-diameter high-temperature model jet and during choked operation of model jets of 0.275-inch to 2.00-inch diameter with unheated air. Frequency spectra and spatial distributions of pressure magnitude are given for the full-scale configuration and model data are used to illustrate probable trends at different operating conditions for the unchoked jets. Model tests for choked operation indicate the presence of a discrete-frequency component, and shadowgraph records illustrate that an unusual type of flow formation is associated with this condition. The frequency of this component is shown to be somewhat related to the shock-separation distances and to nozzle diameter. Laboratory methods of reducing the magnitude of pressure fluctuations from choked and unchoked jets are discussed and sample illustrations are given.

NACA TN 3188

AN ANALYTICAL INVESTIGATION OF AIRPLANE SPIN-RECOVERY MOTION BY USE OF ROTARY-BALANCE AERODYNAMIC DATA. Stanley H. Scher. June 1954. 38p. diagrs., tab. (NACA TN 3188)

A method for analytically investigating the motions of an airplane while in a spin or a recovery from the spin by use of applicable equations of motion, modified wind-tunnel rotary-balance measurements, and spin-geometry relationships is presented and applied to the step-by-step calculation of the spin recovery for one airplane configuration. Difficulties encountered in applying the rotary-balance data in the calculations are discussed, and it is pointed out that certain inconsistencies must be cleared up before the method can be accepted as adequate to give detailed spin-recovery motions for a specific airplane.

NACA TN 3193

AN EXPLORATORY INVESTIGATION OF SKIN FRICTION AND TRANSITION ON THREE BODIES OF REVOLUTION AT A MACH NUMBER OF 1.61. John H. Hilton, Jr. and K. R. Czarnecki. June 1954. 15p. diagrs. (NACA TN 3193)

The present report contains results of an exploratory investigation of the effects of pressure gradient on skin friction and boundary-layer transition of three bodies of revolution at a Mach number of 1.61. The pressure gradients investigated were those obtained on an ogive-cylinder, a cone-cylinder, and a blunt-base (NACA RM-10) parabolic body, all having a fineness ratio of 12.2. Tests were made at zero angle of attack and over a Reynolds number range, based on body length, from about 2.5×10^6 to 37×10^6.

NACA TN 3194

STATISTICAL MEASUREMENTS OF CONTACT CONDITIONS OF 478 TRANSPORT-AIRPLANE LANDINGS DURING ROUTINE DAYTIME OPERATIONS. Norman S. Silsby. June 1954. 32p. diagrs., photos., 3 tabs. (NACA TN 3194)

Statistical measurements have been obtained from photographs taken with a specially built motion-picture camera of 478 landings of present-day transport airplanes during routine daylight operations in clear air at the Washington National Airport. From these measurements, sinking speeds, bank angles, rolling velocities, and horizontal speeds have been evaluated and a limited statistical analysis of the results has been made. An attempt was made to determine the effect of various parameters such as gusty-wind conditions, wing loading, and size of airplane (number of engines) which influence the landing contact conditions.

NACA TN 3195

TIME-TEMPERATURE PARAMETERS AND AN APPLICATION TO RUPTURE AND CREEP OF ALUMINUM ALLOYS. George J. Heimerl. June 1954. 35p. diagrs., tab. (NACA TN 3195)

The application of time-temperature parameters to stress-strain, rupture, and creep data for metals and alloys is reviewed. Some comparisons are made of theoretical and experimental parameters. A parameter based upon rate-process theory was successfully applied to rupture and creep data for aluminum and various aluminum alloys. The value of the constant in the parameter, which provided the best correlation of the data, was determined for each material and application. Master curves of stress against the parameter which summarize extensive data on the aluminum alloys are presented for rupture, minimum creep rate, and time to 1 or 2 percent strain. Predictions of long-time life from short-time data are shown to be possible.

NACA TN 3198

DYNAMIC STABILITY AND CONTROL CHARACTERISTICS OF A CASCADE-WING VERTICALLY RISING AIRPLANE MODEL IN TAKE-OFFS, LANDINGS, AND HOVERING FLIGHT. Marion O. McKinney, Louis P. Tosti and Edwin E. Davenport. June 1954. 45p. diagrs., photos., tab. (NACA TN 3198)

An investigation has been made to determine the stability and control characteristics of a cascade vertically rising airplane model in the take-off, landing, and hovering phases of flight. The model had four propellers with the shaft axes essentially parallel to the fuselage axis and distributed along the span so that the four wings, which were arranged in cascade relation to turn the slipstream downward approximately 90°, were completely immersed in the slipstream of the propellers.

NACA TN 3202

OSCILLATING PRESSURES NEAR A STATIC PUSHER PROPELLER AT TIP MACH NUMBERS UP TO 1.20 WITH SPECIAL REFERENCE TO THE EFFECTS OF THE PRESENCE OF THE WING. Harvey H. Hubbard and Leslie W. Lassiter. July 1954. 35p. diagrs., photos., tab. (NACA TN 3202)

Static tests were conducted for the measurement of free-space oscillating pressures near the propeller in the region where a wing might be located for the tip Mach number range of 0.50 to 1.20. Some measurements were also made near the tips in the region of the fuselage in order to extend the range of existing work from a tip Mach number of 1.00 to 1.20. Some comparisons of these results with theory are given. In addition to a description of the free-space pressure field, measurements are given for some of the same field points with a wing in place. Charts based on experimental data are presented to enable a designer to estimate the maximum free-space oscillating pressures near the propeller for tip Mach numbers up to 1.20.

NACA TN 3204

AN INVESTIGATION OF THE CREEP LIFETIME OF 75S-T6 ALUMINUM-ALLOY COLUMNS. Eldon E. Mathauser and William A. Brooks, Jr. July 1954. 28p. diagrs., photos., tab. (NACA TN 3204)

The results of short-time elevated-temperature creep tests of 75S-T6 aluminum-alloy columns are presented and examined with the objective of obtaining procedures for predicting column lifetime. Semiempirical lifetime curves are obtained with the aid of a previously published column creep theory and are used for deriving column curves. A study is made of the effects of variations of stress and out-of-straightness on column lifetime. Small variations in out-of-straightness have been found to be of little practical significance; whereas, small stress variations change the column lifetime considerably. Plots that do not explicitly include out-of-straightness are presented and may be satisfactory for predicting column lifetime for design purposes.

NACA TN 3214

FUNDAMENTAL STUDY OF EROSION CAUSED BY STEEP PRESSURE WAVES. B. G. Rightmire and J. M. Bonneville, Massachusetts Institute of Technology. June 1954. 30p. diagrs., photos., 2 tabs. (NACA TN 3214)

A fundamental study of erosion caused by steep pressure waves has been carried out. It is believed that the study gives an insight to the possible causes of damage in high-speed sleeve bearings. In particular, the effect on annealed copper surfaces of steep-fronted pressure waves in oil has been studied, the general conclusion being that cavitation of the oil is the probable cause of damage.

NACA TN 3220

AERODYNAMIC LOADS ON A LEADING-EDGE FLAP AND A LEADING-EDGE SLAT ON THE NACA 64A010 AIRFOIL SECTION. John A. Kelly and George B. McCullough. June 1954. 33p. diagrs., 8 tabs. (NACA TN 3220)

Loads data in the form of chordwise distributions of pressure, normal-force, chord-force, and moment-coefficients are presented for a leading-edge flap and leading-edge slat installed on a two-dimensional NACA 64A010 airfoil. Pressure data for various model arrangements are presented in tabular form. The data were obtained for a Reynolds number of 6 million.

NACA TN 3221

STUDY OF THE SUBSONIC FORCES AND MOMENTS ON AN INCLINED PLATE OF INFINITE SPAN. Bradford H. Wick. June 1954. 25p. diagrs. (NACA TN 3221)

A study has been made of the flow about an inclined plate, the forces on the plate, the adequacy of theory in predicting the forces, and the extent to which the force characteristics of the plate are indicative of those of thin airfoil sections.

NACA TN 3222

MEASUREMENT OF HEAT TRANSFER IN THE TURBULENT BOUNDARY LAYER ON A FLAT PLATE IN SUPERSONIC FLOW AND COMPARISON WITH SKIN-FRICTION RESULTS. C. C. Pappas. June 1954. 32p. diagrs., tab. (NACA TN 3222)

Local heat-transfer rates and average skin-friction coefficients on the surface of a heated flat plate at zero incidence to the air stream at Mach numbers of 1.69 and 2.27 are presented for a Reynolds number range of 10^6 to 10^7. The variation of heat transfer with Mach number was found to be the same as that of directly measured skin friction on unheated bodies.

NACA TN 3228

AERODYNAMIC INVESTIGATION OF A FOUR-BLADE PROPELLER OPERATING THROUGH AN ANGLE-OF-ATTACK RANGE FROM 0° TO 180°. H. Clyde McLemore and Michael D. Cannon. June 1954. 62p. diagrs., photo. (NACA TN 3228)

The results of an investigation in the Langley full-scale tunnel of the aerodynamic characteristics of a four-blade, 5.33-foot diameter propeller are presented for angles of attack from 0° to 180°, blade angles from 0° to 67.5°, and a range of advance ratio from 0 to 6.2. The results include a preliminary exploration of vertical descent and a comparison with theory of the rate of change of the normal-force coefficient with angle of attack and the aerodynamic characteristics of the propeller at zero angle of attack.

NACA TN 3230

INVESTIGATION OF DISTRIBUTED SURFACE ROUGHNESS ON A BODY OF REVOLUTION AT A MACH NUMBER OF 1.61. K. R. Czarnecki, Ross B. Robinson and John H. Hilton, Jr. June 1954. 35p. diagrs., photo., 2 tabs. (NACA TN 3230)

An investigation has been conducted in the Langley 4- by 4-foot supersonic pressure tunnel to study the effect of surface roughness on the skin friction and temperature-recovery factor of an ogive-cylinder body of revolution at a Mach number of 1.61. Tests of models having four different surface roughnesses were made at zero angle of attack through a Reynolds number range (based on body length) of 2.5×10^6 to 37×10^6. The drag, base pressure, and surface temperatures were measured for conditions of natural and fixed transition.

REPORT ON THE FLOW PHENOMENA AT SUPERSONIC SPEED IN THE NEIGHBOURHOOD OF THE ENTRY OF A PROPULSIVE DUCT. G. H. Lean. 1954. 15p. diagrs., photos. (ARC R & M 2827. Formerly ARC 11,868; EAP 94)

With a parallel entry duct followed by a straight divergent diffuser of 10° total angle, the flow inside the parallel tube was supersonic provided the outlet pressure of the diffuser was less than a certain critical value. For pressure higher than the critical value, the flow became subsonic at the duct entry, a shock wave was formed at the entrance lip and the rate of air flow through the tube decreased. For outlet pressure less than critical, the flow was supersonic for a distance inside the duct entry depending on the outlet pressure, the flow becoming subsonic further along the duct. Annular type intakes gave lower pressure recoveries than the unobstructed type.

Aeronautical Research Council (Gt. Brit.)
THE USE OF TENSOR NOTATION TO DEVELOP CHARACTERISTIC EQUATIONS OF SUPERSONIC FLOW. C. N. H. Lock and R. C. Tomlinson. 1954. 18p. diagrs. (ARC R & M 2632; ARC 11,584. Formerly ARC 12,206; FM 1341)

General equations of steady motion of a nonviscous fluid are given in tensor notation. It is assumed that one family of coordinate surfaces, x^{a} = constant, are characteristic surfaces, that is, surfaces in which the transverse derivatives of the flow variables are not determined by their values on the surface itself. The condition for this gives the result that the velocity normal to the surface is sonic. The relation which must then hold between the variables on the surface itself is also determined (characteristic equation). Simplicity gives a deeper insight into behavior of axisymmetric and two-dimensional flows.

CRITICAL MACH NUMBERS FOR THIN UNTAPERED SWEPT WINGS AT ZERO INCIDENCE. S. Neumark. 1954. 74p. diagrs., 12 tabs. (ARC R & M 2821; ARC 13,541. Formerly RAE Aero 2355)

This report is a continuation of two previous papers. Subsonic flow is further investigated using linear theory. Methods for calculating "lower" and "upper" critical Mach numbers are given, the solution for the main problem being preceded by a short analysis of critical Mach numbers for the simpler cases of infinite wings. Critical Mach numbers for wings with four different profiles, showing the effect of thickness ratio and of sweepback angle, are determined. The method applies strictly to wings of large aspect ratio. Several conclusions concerning the practical use of swept-wing design are presented.

DETERMINATION OF REVERSAL SPEED OF A WING WITH A PARTIAL-SPAN FLAP AND INSET AILERON. W. G. Molyneux and E. G. Broadbent. 1954. 10p. diagrs., tab. (ARC R & M 2793; ARC 13,308. Formerly RAE Tech. Note Structures 23)

Control reversal due to deformation of a wing with a partial-span flap and inset aileron is considered theoretically for the particular case of a flap held at the root end. The semirigid method is used. An investigation is made for a particular aircraft. The calculated reversal speed is found to be considerably lower than for the straight-forward wing-aileron case. The effect of variation of the degrees of wing and flap constraint is also considered. It is concluded that an increase in reversal speed is best obtained by an increase in flap root stiffness.

Aeronautical Research Council (Gt. Brit.)
WIND-TUNNEL TESTS ON TWO-DIMENSIONAL SUPERSONIC AEROFOILS AT M = 1.86 AND M = 2.48. D. Beastall and R. J. Pallant. 1954. 20p. diagrs., photos., 4 tabs. (ARC R & M 2800; ARC 13,768. Formerly RAE Aero 2384)

Unswept double-wedge and circular-arc airfoils were used to study the viscous effects which are not accounted for in the linearized and shock-expansion airfoil theories. Characteristics derived from measured surface pressures are compared with theoretical values. Schlieren observation was employed to observe the flow and, in particular, the separation near the trailing edges. Wires caused a delay in separation; pitot-tube traverses indicated the velocity profiles. The position of separation was also examined by means of oil.

GENERAL PERFORMANCE CALCULATIONS FOR GAS TURBINE ENGINES. D. H. Mallinson. 1954. 58p. diagrs. (ARC R & M 2684; ARC 10,552. Formerly Power Jets Rept. R. 1214)

An attempt is made to summarize theoretical work carried out during the past few years aimed at discovering the potentialities of the gas turbine as power plant in many fields of application, especially as an aircraft power unit. The performance of various modification of the ideal gas turbine cycle is considered in some detail. Works of various authors are combined and edited in order to depict performance attainable by practical engines. Association between the gas turbine and jet reaction is considered. A method of estimating performance of a simple jet engine is detailed.

VELOCITY DISTRIBUTION ON THIN BODIES OF REVOLUTION AT ZERO INCIDENCE IN INCOMPRESSIBLE FLOW. S. Neumark. 1954. 42p. diagrs. (ARC R & M 2814; ARC 13,756. Formerly RAE Aero 2389)

A new method of determining velocity distribution on slender bodies of revolution in axial flow is expounded, analogous to the linear perturbation method widely used for slender symmetrical profiles in two dimensions. The proposed method leads to simple approximate formulas for velocity distribution on a body, once the equation of the meridian line is given, either in the form of a polynomial, of a square root of one. The method has been used for computing velocity distributions on 12 different bodies, of seven different thickness ratios each, so as to exhibit the most characteristic features in typical cases, and to show some effects of thickness changes.

PRESSURE DISTRIBUTIONS ILLUSTRATING FLOW REATTACHMENT BEHIND A FORWARD MOUNTED FLAP. E. C. Maskell. March 1954. 23p. diagrs., tab. (RAE Tech. Note Aero 2295)

A series of pressure distributions over an NACA.0015 wing with a forward mounted 5-percent chord split flap are presented. The results, obtained by Clarke in 1946, have not previously been published. Two basic types of pressure distribution are identified; and these are associated with fully detached flow behind the flap, and with reattachment of the flow to the wing surface. An intermediate type - corresponding, it is suggested, to reattachment in the neighborhood of the wing trailing edge - is also identified. The physical nature of the flow behind a flap is considered and some ideas on the mechanism of reattachment are suggested.

24-FT. WIND TUNNEL TESTS ON A PROPELLER WITH NACA 16 SERIES SECTIONS. TEST RESULTS AND ANALYSIS INTO MEAN LIFT-DRAG DATA. A. R. C. MacDougall and A. B. Haines. 1954. 18p. diagrs., 6 tabs. (ARC R & M 2602; ARC 11,817. Formerly RAE Aero 2276)

The de Havilland propeller was designed to give good performance at high speeds and the aim of the tests was to check whether, as a result, serious losses in take-off performance had been incurred. Results are reassuring and have been analyzed into lift and drag data for use with the standard single-radius method. Data are compared with results from Clark Y propellers. Improvement becomes greater with increase in Mach number, and so NACA series 16 sections appear to have a beneficial effect on the stalling performance at all tip speeds.

HEAT TRANSFERENCE AND PRESSURE LOSS FOR AIR FLOWING IN PASSAGES OF SMALL DIMENSIONS. J. Remfry. 1954. iv, 56p. diagrs., photos., 4 tabs. (ARC R & M 2638)

This investigation had as its primary object the experimental determination of the heat-transfer and pressure-loss characteristics for air flowing in small triangular, square, hexagonal, and round passages. The heat interchanger models, with a frontage 6 inches square, each comprised from just under 150 to over 2,250 passages, according to their size and spacing. The hydraulic diameter of the smallest tubes was about 0.08 inch. The heat transfer in small smooth passages was found to be less than that usually measured for turbulent flow in tubes of larger size, and there was a tendency for a prolonged transition.

THE DERIVATION OF AIRWORTHINESS PERFORMANCE CLIMB STANDARDS. F. G. R. Cook and A. K. Weaver. 1954. 64p. diagrs., 3 tabs. (ARC R & M 2631; ARC 12,079. Formerly AAEE/Res/239)

A more rational basis for deriving climb standards is proposed. The conception is introduced of a "datum" performance, below which conditions predisposing to an accident exist, and the level of safety judged by an "incident rate" which is the frequency with which the operational performance of aircraft falls below this datum. A standard is chosen so that when the aircraft type complies, the incident rate will not exceed some tolerable value. The effect of engine failure is included by taking account of the probability of engine failure and the associated loss in performance.

MEASUREMENTS OF MID-CHORD PITCHING MOMENT DERIVATIVES AT HIGH SPEEDS. J. B. Bratt and A. Chinneck. 1954. 36p. diagrs., photos., 9 tabs. (ARC R & M 2680. Formerly ARC 10,709; 0.672; FM 1125)

Measurements were made on a 7-1/2 percent biconvex airfoil oscillating about a midchord axis in a high-speed wind tunnel by the method of decaying oscillations. The effect of variation of frequency parameter was also investigated, and conditions giving rise to sustained or growing oscillations at subsonic speeds were examined. Comparison with existing flat plate theories for supersonic flow shows complete disagreement in the trend of the damping with Mach number change, the linearized theory for a flat plate giving an increasing positive value. A recent theory which takes into account the shape of the profile agrees in trend with experiment.

AN INVESTIGATION OF THE DISTURBANCES CAUSED BY A REFLECTION PLATE IN THE WORKING-SECTION OF A SUPERSONIC WIND TUNNEL. A. O. Ormerod. 1954. 16p. diagrs. (ARC R & M 2799; ARC 13,915. Formerly RAE Tech. Note Aero 2084)

In the region above the plate, two main disturbances were found; there was a small disturbance from the leading edge and a disturbance further downstream which had originated beneath the plate. Between the two there was a region of approximately constant pressure in which a model could be located. The forward disturbance seemed unavoidable. Increasing the area of the passage beneath the plate by a recess in the tunnel wall was the most effective way of moving back and reducing the magnitude of the disturbance at the rear.

DESIGN AND USE OF COUNTING ACCELEROMETERS. J. Taylor. 1954. 11p. diagrs., photos., 3 tabs. (ARC R & M 2812; ARC 13,587. Formerly RAE Structures 78)

The fundamental principles underlying acceleration recording by means of a counting accelerometer are analyzed. The essential design requirements for a counting accelerometer are presented. A design that has been specially made to meet these requirements is described. Both mechanical and electrical counting are considered, but mechanical counting is found to be superior.

EXPERIMENTS AT M = 1.8 ON BODIES OF REVOLUTION HAVING OGIVAL HEADS. H. K. Zienkiewicz, A. Chinneck, C. J. Berry and P. J. Peggs. 1954. 11p. diagrs., photos., 2 tabs. (ARC CP 148)

Measurements have been made in the N.P.L. 9- by 3-inch high-speed wind tunnel of the pressure distributions at a Mach number of 1.8 on three bodies of revolution with ogival heads of different shapes at zero incidence. Comparison between the experimental pressures and those obtained theoretically showed good agreement.

ANALYSIS OF FLIGHT MEASUREMENTS ON THE AIRBORNE PATH DURING TAKE-OFF. W. R. Buckingham and D. Lean. 1954. 26p. diagrs., 2 tabs. (ARC CP 156)

Analysis of a series of systematic take-off tests with a Meteor IV aircraft has shown that to a good approximation the minimum airborne path to 50 feet may be treated as an arc of a circle. With this assumption, it is a simple process to derive the mean equivalent lift coefficient used during this part of the take-off. It has been found that the total equivalent lift coefficient used during the airborne phase decreases with increase in the ratio of the airspeed to the stalling speed in a simple manner, which is independent of the thrust/weight ratio when the shortest possible distance is required.

THEORETICAL LOAD DISTRIBUTIONS ON WINGS WITH CYLINDRICAL BODIES AT THE TIPS. D. E. Hartley. 1954. 39p. diagrs., tab. (ARC CP 147)

The effect of tip-tanks on spanwise lift distributions is investigated theoretically for the case of minimum induced drag in incompressible potential flow. Charts enabling rapid estimation of the changes in span loadings, total lifts, and induced drags are presented for a practical range of the ratio to tank diameter to wing span. It is shown how the results may be applied approximately to wings of any plan form, including those with sweep or of low aspect ratio.

CRITERIA FOR CONDENSATION FREE FLOW IN THE R.A.E.NO. 18 (9 IN. x 9 IN.) SUPERSONIC TUNNEL. D. J. Raney and B. Beastall. 1954. 18p. diagrs. (ARC CP 164)

Tests were made to determine the dryness of the air circulating through the tunnel necessary to ensure condensation free flow through the working section. Indications are that a strong shock wave has little effect in causing premature condensation but that local expansions around a model may substantially reduce the critical humidity.

NOTE ON THE EFFECT OF THICKNESS AND ASPECT RATIO ON THE DAMPING OF PITCHING OSCILLATIONS OF RECTANGULAR WINGS MOVING AT SUPERSONIC SPEEDS. W. E. A. Acum. 1954. 16p. diagrs. (ARC CP 151)

An estimate is made of the effect of variation of aspect ratio and thickness parameter on the damping derivative of a rectangular wing performing pitching oscillations in a supersonic stream. After a discussion of various theories of unsteady two-dimensional supersonic flow round airfoils, that due to Van Dyke is combined with the linearized supersonic theory for a rectangular flat plate to obtain the effect on the damping in pitch. The values given apply to wings of symmetrical biconvex section oscillating at low frequency, in a stream of Mach number such that the shock at the leading edge is attached.

ON THE CRITERION OF WING TORSIONAL STIFFNESS. (Sul Criterio Di Rigidezza Torsionale Delle Strutture Alari). Placido Cicala. February 1954. 15p. diagrs. (Trans. from Onore di Modesto Panetti, 1950, p. 45-49)

The official regulations for the stress analysis of airplanes provide criteria which specify in simple form the required torsional stiffness. At the time the Italian standards were established a criterion of stiffness had been introduced which consisted in fixing the maximum angle of torsion produced by a stipulated torsional moment, distributed spanwise by a law proportional to the square of the chord. The present report is an attempt to improve this criterion with due consideration to the characteristics of every type of aircraft in relation to the threats of the cited aeroelastic phenomena, while maintaining the necessary simplicity.

NACA Rept. 1144

AERODYNAMIC CHARACTERISTICS OF A REFINED DEEP-STEP PLANING-TAIL FLYING-BOAT HULL WITH VARIOUS FOREBODY AND AFTERBODY SHAPES. John M. Riebe and Rodger L. Naeseth. 1953. ii, 19p. diagrs., photos., 8 tabs. (NACA Rept. 1144. Formerly TN 2489; RM L8F01)

An investigation was made in the Langley 300-mph 7- by 10-foot tunnel to determine the aerodynamic characteristics of a refined deep-step planing-tail hull with various forebody and afterbody shapes and, for comparison, a streamline body simulating the fuselage of a modern transport airplane. The results of the tests indicated that the configurations incorporating a forebody with a length-beam ratio of 7 had lower minimum drag coefficients than the configurations incorporating a forebody with length-beam ratio of 5. The lowest minimum drag coefficients, which were considerably less than that of a conventional hull and slightly less than that of a streamline body, were obtained on the length-beam-ratio-7 forebody, alone and with round center boom. Drag coefficients and longitudinal- and lateral-stability parameters presented include the interference of a 21-percent-thick support wing.

NACA TM 1372

DROP HAMMER TESTS WITH THREE OLEO STRUT MODELS AND THREE DIFFERENT SHOCK STRUT OILS AT LOW TEMPERATURES. (Fallhammerversuche mit drei Ölfederstrebenmustern und drei verschiedenen Federstrebenölen bei tiefen Temperaturen). Kranz. July 1954. 55p. diagrs., photos., 10 tabs. (NACA TM 1372. Trans. from Zentrale für wissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin, UM 564, Jan. 17, 1939)

Drop hammer tests with different shock strut models and shock strut oils were performed at temperatures ranging to -40 C. The various shock strut models do not differ essentially regarding their springing and damping properties at low temperatures; however, the influence of the different shock strut oils on the springing properties at low temperatures varies greatly.

NACA TN 3191

THEORETICAL INVESTIGATION OF LONGITUDINAL RESPONSE CHARACTERISTICS OF A SWEPT-WING FIGHTER AIRPLANE HAVING A NORMAL-ACCELERATION CONTROL SYSTEM AND A COMPARISON WITH OTHER TYPES OF SYSTEMS. Fred H. Stokes and Charles W. Mathews. July 1954. 50p. diagrs., tab. (NACA TN 3191)

An analysis is made of a normal-acceleration control system as applied to a swept-wing fighter airplane. The results show the response characteristics of the airplane-autopilot combination. The effects that changes in altitude and Mach number have on these response characteristics and the effects of changes in the parameter settings of the system are investigated. A comparison is also made of the normal-acceleration system with pitch-attitude, pitching-velocity, and angle-of-attack systems.

NACA TN 3192

EXPERIMENTAL STRESS ANALYSIS OF STIFFENED CYLINDERS WITH CUTOUTS. SHEAR LOAD. Floyd R. Schlechte and Richard Rosecrans. July 1954. 87p. diagrs., photo., 13 tabs. (NACA TN 3192)

A cylindrical semimonocoque shell of circular cross section was mounted as a cantilever and loaded by a direct shear at the tip. The cylinder was tested with no cutout, with a rectangular cutout on the tension side, and with the cutout centered on the neutral axis on one side of the cylinder. The cutout was successively enlarged through six sizes varying from 30° to 130° in circumference and from 1 and 2 bays in length. Strain measurements were made with resistance-type wire strain gages near the cutout on the stringers, the skin, and the rings for each case, and the stresses obtained are presented in tables.

NACA TN 3196

LIFT AND PITCHING MOMENT AT SUPERSONIC SPEEDS DUE TO CONSTANT VERTICAL ACCELERATION FOR THIN SWEPTBACK TAPERED WINGS WITH STREAMWISE TIPS. SUPERSONIC LEADING AND TRAILING EDGES. Isabella J. Cole and Kenneth Margolis. July 1954. 67p. diagrs., 4 tabs. (NACA TN 3196)

On the basis of linearized time-dependent supersonic flow theory, the lift and pitching-moment derivatives due to constant vertical acceleration are evaluated for a series of thin sweptback tapered wings with streamwise tips. The analysis is valid, in general, at those speeds for which the wing leading and trailing edges are both supersonic. The major portion of the computational results is presented in the form of detailed charts covering the practical range of wing-geometry parameters and Mach number from which fairly rapid estimates of the derivatives may be obtained.

CONSIDERATIONS ON A LARGE HYDRAULIC JET CATAPULT. Upshur T. Joyner and Walter B. Horne. July 1954. 49p. diagrs., photos., tab. (NACA TN 3203. Formerly RM L51B27)

A survey of various types of catapults, which has been made in connection with the problem of accelerating a large (100,000 lb) car along a track to a speed of 150 miles per hour, is given. A hydraulic jet catapult is indicated as the best suited among these catapult types for the purpose intended, and various design problems of this type are treated. Equations are given for calculating the performance of the jet and of the test car, and consideration is given to the physical conditions affecting the jet flow. Design procedures are presented for the jet nozzle and for the bucket on the car which receives the jet and imparts thrust to the car. The expected propulsive efficiency of the jet catapult is given and the effect of a side wind on the jet trajectory is calculated.
